THIS is the species or variety in most general cultivation. Whether the name is botanically correct or not, I cannot say; but it is so far truly descriptive, that *G. intermedia* is about midway in size between *G. Fortunei* and *G. florida*. *G. Fortunei* is without doubt the noblest *Gardenia* in cultivation; but then, as a rule, it blooms but sparsely, yielding but one flower, while *intermedia* or *florida* will yield a dozen. *G. florida* is also most floriferous, but it is too small for the present fashion for button-holes. When the latter return, as they probably will, to their normal and more reasonable dimensions, *G. florida*, and even *radicans*—the latter now so seldom seen—will probably have a great future before them as button-hole flowers. For the present, however, *G. intermedia*, which is all that can be desired in purity and fragrance as well as in size, is in full fashion. It is well, however, to bear in mind that size of flower as well as floriferousness are to a very large extent matters of culture. It is no uncommon thing to see the self-same sort in different gardens of widely differing sizes. A liberal *regimen* develops size; a starving one dwarfs it more in the matter of *Gardenias* than in regard to other flowers. Apart from rich soils or stimulating manures, even the mere addition or withholding of heat and moisture may enlarge or cut down the size of *Gardenia* blooms one-half or more. The particular question of the most suitable

TEMPERATURE FOR GARDENIAS can hardly be said to be settled within 20°. In other words, the most successful cultivators range from 70° to 90°. With a moist atmosphere and plenty of water at the roots the latter is by no means excessive. With a semi-saturated atmosphere it is a fact difficult to overheat *Gardenias*, and time is gained

as well as size developed under what may be called a forcing *regimen*. Gardenias also seem filled with a fuller fragrance when thus rapidly developed. It must, however, be noted that a high temperature apart from a moist atmosphere is specially injurious, and results in bud dropping and heavy crops of scale, spider, or mealy bug. The former mishap is one of the most disappointing *contretemps* in Gardenia culture, and the presence of the latter pests may generally be accepted as proof of the lack of good cultivation.

FLORIFEROUSNESS is also largely a matter of manipulation or culture. Gardenia blooms should never be cut with their branches attached, but each picked off separately, and for this obvious reason. It is the natural habit of Gardenia shoots to produce three or more shoots from the base of each flower bud; cut the flower with its branch and all these are removed. Pick the flower out with its elongated leaves intact, and the whole of these shoots grow into flowering branchlets furnished with a terminal flower-bud. By careful attention to this apparently small matter, Gardenia plants advance in prolificness by the rapid leaps and bounds of multiples, by threes or more. Thus the one shoot becomes three, the three nine, the nine twenty-seven, the twenty-seven eighty-one, and so on. In this way are flowers not only multiplied, but the plants advance in bulk. Nor is this process of multiplication only repeated once a year, but twice. For the whole tendency of the present high and forcing culture of Gardenias is to compel the plants to yield two crops a year instead of one, as well as to have both crops finer and more plentiful than they used to be. In relation to this

SECOND CROP OF BLOOM, the saving of time incidental to high and forcing culture becomes of the greatest importance. For example, assuming the first crop of flowers to be gathered in March, a supply of wood may be made and sufficiently ripened to yield a second crop in September and October. Neither is it found in practice that the autumn or winter bloom seriously lessens or injures the spring flowering of the plants. The demand for Gardenias has now become so insatiable, that no doubt a continuous supply will have to be forthcoming. Cultivation, however, can hardly be said to have yet reached this stage, though it is seldom that a stray Gardenia bloom cannot be found in Covent Garden or other markets. But the chief seasons at present are the early spring and late autumn, and it is a wondrous advance on the ancient culture of these plants that resulted, as a rule, in a scanty supply of blooms once a year to have forced them to yield two plentiful harvests within the twelve months. In several respects, too, this second harvest is better, as well as more valuable, than the first. The first is very apt to come in with a rush. There is a prodigality of Gardenias succeeded by a famine, the flower seemingly preferring to run in abreast in battalions many hundreds strong. We have a magnificent feast of Gardenias, succeeded sometimes within a short time by a complete fast. A good deal may be done to prolong the feast by having several small pits or houses instead of one larger one, as well as by growing Gardenias in pots. But grow them how or where we may, Gardenias have a strong tendency to bloom abreast in the spring. But in autumn this inconvenient tendency is far less pronounced, and the plants unfold their harvest of sweetness and beauty in a more leisurely way, extending it over two months or more. The advantages of this habit of continuous blooming in the autumn or winter can hardly be over-estimated. But, it may be asked, is nothing more than liberal diet and forcing conditions of temperature and atmosphere needful to insure this double harvest of Gardenia blossoms within the year? Yes, a rest is needful, and some cultivators also think a lightening of the spring load of bloom useful in adding to the numbers and size of the autumnal ones. Whether the latter is needful or would prove useful depends on the strength of the plants. Where these are vigorous and in robust condition the dual crop does not seem to hurt

them. As to the so-called rest, it is only comparative. The plants should be kept somewhat cooler and drier for about a month or six weeks. Much more air should also be given during the resting period. This tends to harden and consolidate the growth of embryo flower buds, and also makes them more sensitive to respond to heat and moisture when these are given, so that really time is saved and not lost in the forcing of Gardenias by an interregnum of rest between. The question of

BOTTOM HEAT or no heat for Gardenias may be said to be still in suspense. They are equally well grown and bloomed without and with bottom heat. In all cases, however, in which the harvests of bloom are expected from the same plants within the year bottom heat should be provided. Bottom heat, in fact, may be said to be the very key of the position of a rapid and safe start. With the roots sufficiently moist and in vigorous health a bottom heat of from 75° to 85° may not only be applied with safety, but with the happiest results in hastening the development of the buds and their full expansion with perfect blooms.

NEW FRENCH CHRYSANTHEMUMS.

THE Chrysanthemum as a florists' flower was never more popular than it is to-day; as a decorative plant it is more and more extensively cultivated every year. Chrysanthemum exhibitions, the fine displays made in the Temple Gardens and in sundry of the London parks during the autumn months, have shown how easy it is to have a conservatory gay with flowers during the duldest and most foggy time of the year. Quite recently I have read that one of the large conservatories in the Royal Gardens at Frogmore was last season made very attractive by means of hundreds of Chrysanthemums, all of which is most encouraging. In no other country is the Chrysanthemum so well grown as in England, near Liverpool, and in London especially, but it is to some of us a source of regret that while we cultivate this plant so well nearly all the new kinds are imported from the Continent, and we hope for the time to come when every grower will save seed and raise a few new seedlings every year. As it is, most of the new varieties are raised either in the Channel Islands or in France. With regard to those from France I am indebted to M. Lemoine, the well-known horticulturist of Nancy, for the following select list of kinds recently sent out.

1. EARLY-FLOWERING VARIETIES (viz., those which flower from October 15 to November 15).—Alexandre Dufour (Délaux), Japanese, full flower of a rich violet colour; Amarantina (Délaux), Pomponé, perfect in shape, purple amaranth with white points; Curiosité (Boucharlat), Pomponé, poppy colour with gold centre; Etincelle (Lacroix), Japanese, very large and very dark crimson tipped with gold; Ile Japonaise (Délaux), large and very full petals curled, violet-rose with a light silver tint; Mdle. Lacroix (Lacroix), Japanese, rosy white changing to pure white; Mdle. Maney (Délaux), Pomponé, very full, delicate rose, the reverse of the petals tinted silver.

2. POMPONES.—Apothéose (Lemoine), flowers full, purple-carmine; Arbre de Noël (Lemoine), flowers very full, brilliant orange tinted with scarlet; Laïs (Lemoine), flowers of medium size, sulphur tipped with gold; La Mascotte (Lemoine), flowers full, reddish brown and violet; La Traviata (Délaux), flowers brownish red, tinted with dark scarlet; Lavinia (Lemoine), flowers middle-sized, light violet; M. Robillard (Délaux), late flowering, lilac-rose edged with white; Séduction (Lemoine), flowers full, reddish brown; Volcan (Lemoine), flowers small, mahogany red.

3. LARGE-FLOWERING VARIETIES.—Gloire Lyonnaise (Boucharlat), flowers middle-sized, piped petals, centre white, with reddish brown tips; Grenadière (Boucharlat), flowers large, garnet red pointed with gold; Jeanne d'Arc (Lacroix), flowers snow white, reverse of the petals lilac; Mdle. Croizette (Lemoine), flowers dark rose, changing to delicate rose; Mdle.

Madeleine Tezier (De Reydellet), late flowering, perfect in form, snow white, flowers in bouquets; Tragédie (Lemoine), flowers full, violet-rose; Vereschagine (Lemoine), dark rose spotted with purple.

JAPANESE.—Admiration (Lacroix), petals long and tubular, delicate lilac, turning pure white in the centre; Fr. Délaux (Délaux), flowers very large and full, crimson-red, tinted with fiery red, centre curled, reverse golden; Général de Lartigue (Délaux), flowers very full, petals curled, fiery red, reverse yellow; J. Délaux (Délaux), flowers full and very large, dark brown, tinted with crimson, reverse gold. Among the Japanese varieties sent out in 1882 several did not flower. This list will be interesting to our own growers, and allow me to suggest that as the same name is now applied not unfrequently to very dissimilar varieties, the *bona fide* raiser's name be added on the labels of all exhibited plants, as is generally done in the case of the Auricula.

F. W. B.

Eucharis amazonica.—We grow this queen of winter flowering plants here in a large Pine pit or stove plunged in tan in various sized pots, and great quantities of bloom have been cut from it throughout the winter months. Fresh tan is put into the pit in the spring and autumn of each year, and the plants are in no way subjected to the drying-off system. I cannot speak too highly of this system of growing Eucharis, for the amount of bloom produced by these plants throughout the past winter has been and is still something very remarkable.—G. DRUMMOND, *Wilton Park*.

Tar varnished pipes.—I know of nothing more pernicious to vegetable life than heated tar effluvium, and I know of only one effectual and immediate means of eradicating it, and that is to remove the pipes from the house and fire them until they are nearly or quite red hot. A more simple and inexpensive means (though not so quick or certain as fire) is to clear the house of everything as far as possible, throw open all means of ventilation, and then get the pipes as hot as it is possible to get them; then dress them two or three times with limewash, so as to get a thick coat on them. If one dressing is not found to be effectual, the pipes should be scraped or washed and again heated and dressed as before; but if the water in the pipes can be made to boil so much the better, as the limewash will have greater power to draw and absorb the tar from the pores of the pipes in which it is imbedded.—R. WESTCOTT, *Raby Castle, Darlington*.

—In order to obviate the injurious effects of tar varnish on hot-water pipes your correspondent must make the pipes hot, at the same time opening the ventilators to allow the destructive gas to escape. Get sufficient lime fresh from the kiln, put it into a bucket, and slake it with water, allowing it to boil well. As soon as the boiling ceases give the pipes a good coating with the lime, applying it with a brush all over them. Allow it to remain on for several weeks, when it may be removed by keeping the pipes damp with a syringe for a few hours. It may then all be scraped off. Allow the pipes to get thoroughly dry; then give a coat of thin paint made of boiled linseed oil and lamp-black.—JAMES SMITH *Waterdale*.

—“Subscriber” need not remove the tar varnish from his hot-water pipes. He should clear his house of plants, keep on a strong fire to keep the pipes hot, with plenty of ventilation for a few days, when all smell will disappear, and all danger to plants will be removed. This is our own practice always when we blacken our pipes with tar, and we never have any bad results herefrom.—JAS. BARRON, *Old Meldrum, Aberdeenshire*.

—In removing tar varnish has your correspondent ever tried alcohol methylated or turpentine? I think these would clean his piping. He could then paint them with “calceum” or the “Torbay” paint?—READER.

Campanula Vidalii.—This is one of the most useful of plants for the conservatory or greenhouse, and as a Campanula one of the most interesting in the genus. It is a half hardy perennial of dwarf shrubby habit, forming a woody stem about

9 inches or a foot in height, on the top of which short branches clothed with serrated fleshy leaves about 3 inches long are borne in abundance every year. Some of these branches lengthen out to about 2 feet, and bear on the upper half pure white bell-shaped flowers, drooping and very fleshy. These shoots after flowering require to be cut away, as they do not branch again, the shorter ones and others newly formed on the top of the stem being those from which the flowering shoots are developed in the following year. We grow our plants of this Campanula in a cool frame in winter, potting them in the autumn in a good loamy soil, so that a steady growth may go on through the winter. As the shoots lengthen, the plants are removed into the greenhouse where their flowers have a striking effect amongst Begonias, Fuchsias, &c. Seeds ripen freely every year, so that a stock of this plant is easily procured. It is said to be quite hardy, and although I have never seen it tried-out-doors all the year round, it may yet prove a useful plant for the herbaceous border as well as for the greenhouse.—B.

ROSE GARDEN.

SPRING AMONG THE ROSES.

WRITING on April 4, I can say we have had four days and one night of spring, for the first two nights of April registered 10° of frost. Already the sap has started on its course through the Roses, and is trying to find its way along blackened pith and seared-looking wood. In many cases it seems at a loss to find its way, and runs into tiny transparent silvery-looking globules on the heft of the knife. They glisten like quicksilver in the bright sunshine, and suggest new hopes as well as fresh dangers. Only a few days since all the Roses were firmly bound in the cast-iron-like fetters of frost of a strength of 20°. Every started bud and all spongy soft wood are destroyed. And yet hardly has the sun come forth with any vernal warmth than the arrested sap bounds once more to the front and asserts its presence and power. The latter hardly seems impaired by its stoppages, for in all Rose shoots not hopelessly killed the moving sap is found. So plentiful, indeed, is it in injured shoots and branches, that it seems more like a mere solution into fluid of what the frost had rendered solid than a conveyance of fresh sap from the roots. Be that, however, as it may, the spring has once more filled our Roses with fluid in an active and growing state. Hardly has it breathed upon our Roses than they live anew and grow afresh, and this state of things summons the rosarian to prompt decision and immediate action. The duty of those who had not pruned their Roses is tolerably clear—to prune forthwith without a day's delay. March severities will also have indicated pretty clearly the points to prune to. In general terms all injured wood should be cut off, and the pruner should go back to a healthy bud on sound wood. In many cases this will be, to the pruner of dwarfs, at the ground line. Neither is this so great an evil as it may seem, unless on account of the loss of time and material. Cutting to the ground line will, renew the youth, and brighten and improve the ultimate results in not a few Roses. As to standards, many of them will also have to be cut back to the Briers, which is synonymous to the ground line in dwarfs. Dormant buds seem to have, on the whole, passed through this black March better than growing branchlets. This is singular, one bud bearing cold better than many.

Those who had already pruned before the terrible frosts of March will have much more difficulty in deciding what to do. The frosts have so many different effects on different varieties, and also affects the colour of the shoots so differently, that it is really a difficult matter to test the amount or extent of the injury sustained. The pith test is perhaps the safest and most reliable. Where the pith is green and of a proper character, the shoots will force adventitious buds and recover. This may be accepted as an axiom however hardly bit the wood may be by the frost.

But where the pith is black or brown, or seems damaged or decomposed, the Roses will generally become diseased or die outright. But they will not do so at once and right away. No; those shoots with the worst pith often break the soonest and the strongest and look the most promising. But these breaks and blooms are but the haste and hurry of disease on death-stricken plants. Could one only gauge the depth of the injury to the pith and cut beyond that, the Roses might mostly be saved. But the injury to the pith is most difficult to trace. In many cases it is not a straight line of injury from top to bottom; pieces are missed here and there. Sound pieces are found around harder nucleus of buds, and then again the pith is blackened, and thus cutting to the sound healthy pith becomes difficult in practice. It is, however, really the only safe and general rule that can be laid down after frost-bites. It needs wonderful courage, however, to adhere to it. We began the other day on our dwarfs to pick out the injured wood by the pith test, and gave it up. So many promising buds had to be sacrificed, that we decided to see what they promised to be after a week or so before proceeding further.

The colour of the wood test is even more uncertain and capricious. At first sight the darkest or yellowest wood might be thought the most severely frost-bitten. But this does not seem to be always the case by any means, as tested by actual dissection. Among all these difficulties of dealing with frost-bitten Rose wood there is one general principle that may bring much comfort to semi-distracted rosarians. It is this—the more severely they prune, the better for the future well-being and beauty of the plants. The Roses are weakened more or less by the cold; hence the more they are reduced in area, the less will their impaired strength have to do, and the more effectually will they do it. Thus, by concentrating vital force by pruning, we virtually augment it. Consequently, though we must have fewer flowers and a later harvest of blooms, we may even yet have finer ones through the cutting severities of this late winter, now, it is to be hoped, merged for good in the vernal genialities of real spring weather. If so, rosarians may yet be able to say of March, 1883, with the French lady, "that any weather is better than none at all."

D. T. FISII.

Rose Cheshunt Hybrid.—We have here a specimen of this Rose, now in full bloom, on the roof of a house from which frost is excluded. I counted on it the other day between 80 and 90 fully expanded Roses and about 200 buds, and we have cut about four or five dozen blooms off it already. The plant covers about 9 feet of roof, and is planted in a border 9 inches wide and 3 feet long.—J. W. LONGROOT, *Pull Court, Terkesbury.*

Gloire de Dijon Rose.—Of all the Roses in cultivation, this, in my opinion, is the most useful. It is the last Rose of summer and the first of spring. Indeed, with two or three plants in a cool greenhouse, and the same number on any wall out of doors, a constant supply of blooms may be had from February until November. In constitution it is most robust, as there is no situation in which it will not succeed, and I cannot remember a Gloire de Dijon dying of either disease or old age; one of our plants here I know will soon be out of its teens, and still it grows as robustly and blooms as freely and profusely as the youngest of them. During the last three weeks we have cut at least two hundred blooms from this plant which occupies a restricted place in a cool conservatory. Another one which was planted in a miniature form at the end of an unheated Peach house three years ago has this spring produced five hundred buds and blooms; and this is only one crop, as successional ones will follow until the end of the season. If this Rose has a fault at all, it is in being over-floriferous. In many instances it is allowed to injure itself through bearing too many flowers; if left to itself there will be a bloom from every eye, and there is hardly any way of preventing this, except cutting off the bloom. The shoots should be cut well into the main stems, and this will induce fresh shoots to push

forth, and it is these which, before long, bloom again. At the same time, next year's crops must be seen to, and we find that the best way to provide for these is not to depend wholly on spur pruning, but to lay in a number of young shoots, which always spring from the base of healthy plants, and in the winter time some of the oldest of the branches may be cut away to make room for these. Sometimes these young shoots may be 10 feet or 12 feet in length, but this is none too long, as in spring they will break regularly, and produce a host of massive gorgeous blooms. Out of doors the only profitable way of growing this Rose is against a wall where it will have plenty of head room. In dwarf or standard form in a bed it is lost. As a natural rambling bush it would be better, but against the walls of mansions, villas, cottages, churches, it is at home. A well-drained bed, with plenty of rich soil and a never-failing supply of moisture, are its only wants throughout the season; and should green fly appear at any time, liberal syringing will at all times dispel it.—J. MUIR, *Margam.*

Roses indoors.—I never saw such a fine display of Roses in March as I saw the other day in a house devoted to their culture at Woodwater Park, Weybridge. On the roof were the following kinds, vigorous in growth and one mass of bloom, viz., Glory of Waltham, Souvenir d'un Ami, Gloire de Dijon, Céline Forestier, Anna Alexieff, Maréchal Niel, Lamarque, Mdle. A. Wood, and Mdme. Levet, a grand Rose. These are planted out in a well prepared inside border. A stage in the centre of the house is occupied with finely bloomed Hybrid Perpetuals and Teas in pots. There was no mildew, and the plants were otherwise unblemished.—A. I.

Rose leaves (A. M.).—The Rose leaves which you enclose are attacked by red spider; syringe them well with water, taking care that the undersides get the full force of the deluge of water. Red spider has a great dislike to moisture; if possible keep the air about your Roses rather damper than you have been doing. If this is not sufficient to stop the attack, syringe with 4 ounces of sulphate of lime, 2 ounces of soft soap well mixed, and then dissolved in 1 gallon of hot water.—G. S. S.

ORCHIDS.

LARGE VARIETY OF DENDROBIUM NOBILE.

THE annexed illustration represents the exact size of a flower of *Dendrobium nobile* sent to us a short time ago by Sir William Marriott, Down House, Blandford. Not only was it large, but both it and the flowers which accompanied it were unusually well coloured, their sepals and petals being flushed with a rich deep purplish carmine, while the massive labellum in each case was marked with an intensely deep maroon-crimson blotch. Such varieties as this are extremely rare, many Orchid cultivators of wide experience having never seen any form of *D. nobile* at all equal to it. An appropriate varietal name for it would be *giganteum*. It is a companion variety to that called *nobilis*, which bears flowers that measure just upon 4 inches in diameter, and which are extremely deep and rich in colour.

Orchids in flower in Mr. Bull's nursery, Chelsea, include the following noteworthy kinds: In the Cattleya house are many fine varieties of *C. Mendelli*, just commencing to flower, and taking the place of *C. Trianae*. The rarely seen *C. speciosissima* is finely in bloom, and one plant bears two large flowers in one sheath. This kind can only be compared with some of the finest forms of *C. gigas*. Among the *Laelias* is a new variety of *L. elegans* called *Mastersi*, in the way of the beautiful variety *alba*, but the rich amethyst colour of the lobe of the lip is carried round the rim of the throat, which, with the white sepals and petals, renders the flower extremely handsome. Of *Cymbidium eburneum*, the very distinct variety *Dayanum* is finely represented by several flowering specimens. This variety may be at once distinguished from the type by the broad

purple band which runs down the middle of the labellum. A new *Oncidium* called *cryptocopsis* is worthy of note. It is in the way of *O. serratum*, and similar to another new and rare kind which has flowered here for the past few seasons, called *O. tetracopsis*. The flowers are large, yellow and brown, borne on a long spike. Among rare *Dendrobiums* is *D. Draconis*, a very handsome species belonging to the nigro-hirsute or black hair-stemmed section. It resembles *D. infundibulum* somewhat, but the markings on the labellum are of a deeper, brighter orange-red, a colour which contrasts well with the waxy white sepals and petals, which shine as if varnished. In habit of growth and mode of flowering it is similar to *D. infundibulum*. *D. leucolophotum* is another new and rare kind. It may be best described as being like *D. barbatum*, but is of taller growth, the stems more resembling those of *D. superbiens* than any other. The spikes are borne

the spike to branch, a character rather uncommon in this *Orchid*.

LONGEVITY OF *ODONTOGLOSSUM CRISPUM* AND *VEXILLARIUM*.

DOUBTLESS there are plants of these *Odontoglossums*, as of other *Orchids*, that after getting over the hardships consequent on their importation grow for a time, and then die off in a way that gives rise to the question of their ability to last long under cultivation. But there is proof enough of an opposite character to show that there is no ground for coming to the conclusion that these, in common with most *Orchids*, will not go on for an indefinite time provided the treatment is such as is conducive to their healthy existence. Most growers, I think, will have found that *O. vexillarium* is not so easily kept in good condition as *O. crispum*, although when once it gets fairly established after

losses that take place in this way, although outside the question now raised, have much to do with the impression frequently entertained as to *Orchids* being short-lived.

A good many species that used to be looked on as impossible of being long kept in a healthy state do as well as others supposed to be more enduring, such, for instance, as *Cattleya citrina* and *Cymbidium eburneum*, that, when the right management is hit upon, continue to grow as free and healthy as the commonest *Dendrobe*. A good many years back when the spot disease (brought on by semi-darkness, insufficient air, and a reeking atmosphere) was so rife, the conclusion came to by some looked upon as authorities was that the highly artificial conditions under which *Orchids* required to be grown were such as not to admit of their having more than a limited existence. But now, when a more reasonable course of treatment is followed, little of the disease is seen. Those who have had anything to do with *Orchids* will have learnt that with them more than other cultivated plants there are some species much more delicate and difficult to deal with than others; neither is there anything surprising in this if a little reflection is directed to the widely varied conditions under which they grow naturally. When the extent of this is fully realised, the wonder is that so many species from so many different parts of the world can be induced to thrive in the same house.

T. BAINES.

Large flowered variety of *Dendrobium nobile*, from Sir William Marriott's collection, Down House, Blandford.

from the top of the stems, and the flowers are pure white. *Odontoglossums* form the finest feature in this nursery at present, and the large display of them in bloom includes some rarities. *O. Ruckerianum* is represented by the finest form we have ever seen, its flowers being fully twice the usual size and superbly marked. Among the numerous forms of *O. gloriosum* is one called *pictum*, remarkable for the close, yet large, spike of flowers, which are far deeper in the markings than those of any other in the collection. The name is appropriate, and the plant well deserves it. Amongst the *Alexandrae* varieties are some lovely forms, particularly those with a suffusion of rosy purple in the flowers. *O. Andersonianum*, *O. mulus*, *O. hebraicum*, *O. triumphans*, and a host of others are also in fine condition. The *Harryana* section of *Masdevallias* is just beginning to bloom, and already such splendid forms as *brilliantissima*, *vivicans*, and *lilacina* enliven the *Masdevallia* house with their glowing colours.

Odontoglossum Andersonianum.

—We omitted to mention in our report of the last meeting at South Kensington that a remarkable specimen of this *Orchid* was shown by Mr. Clinckaberry, Forby Hill, Enfield. It bore a spike nearly a yard long, carrying twenty-five large flowers having a creamy white ground and abundantly spotted with chestnut-brown. It was one of the finest forms of *O. Andersonianum* we had seen. There was a decided tendency in

importation it usually goes on freely enough where there is a continuance of the treatment first found to answer. Not a few of the failures that take place in *Orchid* culture are traceable to a want of following the well-proved maxim of leaving well alone—a mistake that usually arises from an inclination to adopt the treatment someone else follows who seems to get on faster. These two *Odontoglossums*, particularly *O. vexillarium*, have not been so long in cultivation as some *Orchids* in a way to give absolute proof of their ability to keep on in a healthy condition for an indefinite time; but there are enough examples of *O. crispum* of the early importations as full of strength and vigour as ever they were to give promise of their going on equal to the most enduring. If the fact that so many more of these plants have been imported than evidently are now in existence was taken as conclusive that they necessarily wear out and are short-lived, the case might be said to be proved, for there is little doubt that a large percentage of the vast quantities of these *Odontoglossums* that for many years have now been brought over are non-existent; and the same may be said of other *Orchids* to a greater or less extent proportionate to the ability the individual species possesses to bear hard usage—not alone the hard usage inseparable from collecting and transit, but the still further weakening by being cut up into small bits in the manner often practised, to which collectively is attributable the death of so many. The

Oncidium inscriptum, like a good many other *Oncids*, is deficient in brilliancy of colours, but nevertheless, owing to the length of its flower-spike and its thick, fleshy, or waxy-looking flowers, it is not without interest. A plant of it in the cool *Orchid* house at Kew bears a spike 13 feet in length, with branches at intervals of 6 inches about a foot or so long. The flowers are nearly as large as those of *Oncidium crispum* and somewhat similar in shape. They are chocolate-brown, with a narrow margin of pale yellow round the undulated edges. To lovers of the curious amongst *Orchids* this *Oncidium* presents attractive features even in collections in which more gorgeously coloured flowers predominate. At Kew this *Oncidium* flowers freely every year, and there it is where one expects to find such interesting, though not showy, plants.

Phalænopsis Parishii.—The silvery green foliage with which this pretty little plant is furnished distinguishes it from the rest of the *Phalænopsids*. Its flowers, which are borne on a short spike, vary from two to six on each spike, and are about the size of a sixpence. The sepals and petals are creamy white, well reflexed so as to give prominence to the white column with its purple spotted base, and the turf-cutter-shaped labellum, which is dull purple in colour. The lip hangs by a thread; therefore if blown upon it moves quite freely, and on its top there is a moustache consisting of long bristle-like white hairs, or rather four or five long and the rest shorter. This *Phalænopsis* is a native of Moulmein, and is now in flower in the East Indian *Orchid* house at Kew.

Eulophia streptopetala, now in flower at Kew, is an old-fashioned and rare plant, not very handsome if judged by the standard of brilliant colours and large flowers, but still interesting. It is terrestrial, has bulbs and foliage resembling those of *Calanthe veratrifolia*, and produces a flower-spike about 2 feet long, which bears about a dozen flowers of the size of those of *Lælia harpophylla*. The form of these flowers is somewhat singular, reminding one of a bird just alighting, the two petals being fixed horizontally and curved exactly as a wing is. These wing-like petals are primrose-yellow, and the *Cattleya*-like lip is of the same colour, with chocolate-brown sides. The sepals are green, spotted with brown. This plant thrives in a cool house and should be potted in a mixture of peat, loam, and Sphagnum, and given plenty of water while growing. It is a native of South Africa, and, like many of the terrestrial *Orchids* from that region, requires a long period of rest after making its growth.

IN MADEIRA.

ESCAPING from the grey northern seas—too often tormented by storm—into the gardens at Madeira is one of those changes grateful to all, but most so to those who have passed through a cold and flowerless English winter. Reaching the steep shore, a bank of purple is noticed between two houses. It seems a plot of Wallflowers with a purple hue, but one who knows the place says it is the *Bougainvillea*! We have all heard of its effects in some warm countries, but words cannot do justice to its superb colour and abundant blossom. There is the splendid rosy purple kind which is not seen in England, and it runs over bower and wall and trellis and house, becoming in early spring a flood of the richest purple-rose. Flowering in winter this kind is not so easily grown in England as the rose-coloured one which blooms in summer. Not less surprising is the red variety, or species, never seen with us, for probably the same reason. A large, second-story verandah in Count Lambert's house has its pillars clad with this red kind, and the effect is very fine. There seems no limit to the free growth of either. The commoner *B. glabra*, often seen in England, is also here in flower, but it is scarcely noticed beside the other kinds. Near Major Bolton's house there are some wide trellises covered with *Bougainvillea* to such an extent that the house seemed to float in a flood of this glorious creeper's coloured leaves.

Though the *Bougainvilleas* are the showiest plants, and their effect on rock, wall, or house both beautiful and new to the northerner, it is no less pleasing to see many old friends of the warm greenhouse here all happy in the open air and in free bloom—Cherry Pie, *Pelargoniums* in various colours, *Plumbago*, scarlet *Salvias*, large red *Hibiscus*, *Acacias*, the Coral Tree, *Calla Lily*, *Bignonia venusta*, and others; the scarlet *Passion Flower*, *Ice Plants*, the beautiful *Macartney Rose*, the New Zealand *Speedwells*, the bright-flowered *Russelia*, here with many coral flowers on graceful bushes in the open air; *Azaleas*, white and red, along with our *Rosemary*, *Periwinkle*, and an occasional *Pansy*, and many *Roses*; the Trumpet Flower, white and orange; *Camellias* in large bushes, with *Rhododendrons*, *Oak-leaved Pelargoniums*, fragrant and spicy, the showy *Gazania*, and many others. Among these flowers, those that strike one most for their value are the *Bignonias* and the bright scarlet *Passion Flower*. The last grows as high as 40 feet, and freely bears its vivid flowers. It is, we think, the Vine-leaved *Passion Flower*, and it ought to be in every stove in England.

BIGNONIA VENUSTA is a noble climber, with a bold free habit and long graceful shoots, with the handsomest heads of orange blossoms one could desire. It is well to see it here, because it shows us the error of attempting the culture of such a plant in a pot in England or in any place where it has not plenty of room above and below. In a roomy, warm greenhouse a fine feature may be made of this plant. Our old friend *Euphorbia jacquiniiflora* is a most graceful shrub here, best perhaps as a standard with a stem 2 feet high, and breaking then into a number of long shoots, brightly set with blossoms, and more graceful in habit than any *Fuchsia*. The plant, as grown in England, is too small for its rare habit to be seen. The old *Poinsettia* is a big shrub here, and some *Aloes* are round bushes, one with very handsome large coral blossoms. There are myriads of the bells of *Abutilons*, and *Cannas* 10 feet high with showy red flowers, and the great Cape *Anaryllis* with a white and pink head of flower more than a foot through, and the rich purple *Ipomæa*, and the *Vinca rosea* and blue *Eranthemum* of our stoves—all in flower in the open air, with the fringed Chinese *Iris*, the Florentine *Iris*, *Scilla peruviana*, the common *Periwinkle*, and everywhere the *Heliotrope*, the ground shaded by great *Campor trees* and Indian Fig. Among climbers, *Thunbergia laurifolia*, with its large purplish flowers, is superb over trellised archways, the foliage is so good and the flowers very numerous. In our stoves this does not often get a chance of showing its vigour and beauty; it

is a very fine climber. The *Lantanas* show over the walls by the streets their varied flowers, so vigorous are they here, though they are not so welcome as the fragrant and spicy *Oak-leaved* and many other *Pelargoniums*, *Heliotropes*, and *Azaleas* that perfume the warm air.

The *Belladonna Lily* is in wild profusion, and becomes a weed, quantities of it being thrown out in the hope of eradicating it. The blue African *Lily* (*Agapanthus*) also grows quite freely, and must be a pretty feature in summer with its many blue heads. The true wild *Hyacinth*—parent of our cultivated *Hyacinth*—is wild, or apparently so, in various places.

THE *PELARGONIUM* is the joy of the gardens in winter, and no doubt for many months, not in circles or lines, but growing softly and naturally, now forming a hedge, now a tall shrub. A line of scarlet varieties look over a wall, bounding Dr. Grabbam's garden, towards the sun. Over them lean the branches and foliage of large old evergreen trees; below the grey wall. Seen from a point outside and below the wall, this formed a curious and brilliant picture such as any artist might be proud to paint. In Major Reeve's garden there were high fences on each side of the main walks formed of an *Oak-leaved* species in full bloom. It is indeed a paradise for *Pelargoniums*, and the new kinds sparkle with pure and brilliant colour in Mrs. Hinton's and various other gardens where they have taken the trouble to obtain them. The old citron-scented and other Cape *Pelargoniums* are also all happy as bushes in the open air and in every garden. The *Aloes*, tame and poor in our glasshouses from want of bloom, here sparkle with many graceful spikes of flower; when they form old and wide bushes their effect is good. Growing over a high wall bordering Mr. J. Blandy's garden they project into bold masses. Relieved by similarly free and large masses of the light blue *Plumbago* of our greenhouses, and the vivid scarlet *Passion-flower* too seldom seen in our warm houses, they, all untrained and untouched, combine to form a rare garden picture.

THE NOBLY-FORMED *Ruscus androgyneus*, a native of the island, is one of the most valuable plants in it, and one of the best ornaments of its gardens. Its fine form of leaf and bold, graceful habit make it one of the noblest plants for a high pillar in a conservatory or a piece of high wall in any house. It will do with very slight aid in the way of artificial heat, and would do in an unheated house. Here it grows freely in the open air. There used to be a good plant of it in the Crystal Palace, but it is not so common as it deserves to be in our houses. There was a very handsome wreath of it in Prince Demidoff's garden at Florence. It has various uses, and would be admirable in connection with good stonework. A plant over the entrance to Mrs. Cossart's quinta wreaths round the stonework in a very fine way without concealing it.

The fine effect that should be got in the gardens is put out of the question by the same practice that mars our own efforts—the mixed shrubby kind of planting which hinders all definite and many happy special effects. Where the range of form and foliage is so great as the climate permits of here, the good effects might be more varied and finer than usual. But the muddled, meaningless effect of the shrubbery in England is repeated all over the world in gardens. We are so much concerned with the individual, that we do not consider how much we lose by the way it is placed. Only here and there where a fine Alexandrian *Laurel* covers 50 feet of a high wall, or a *Monstera* with noble foliage forms a group by itself, or an enormous many-stemmed *Strelitzia* springs up in the air, making us forget all but its own noble *Banana-like* growth, do we get an idea of how much is lost by the usual "mixture." Owing partly to the vigorous growth of the plants, it is the fashion here to clip them till their natural shapes are lost, and the flowering beauty of the plant is destroyed too. Things like the double *Spirea*, in which flowers spring from the sides of old branches forming wreaths, can show no beauty when cut in as with a scythe, looking at last like cushions on the top! They should be cut in without de-

stroying their natural form, and thinned out at the same time. The *Camellias*, of which there are groves in some gardens, are not, so far as we could see, shorn in this way, but they are so much in want of thinning that the flowers are smaller than they should be. The trees are often a dense mass of shoots, the leaves less fine than is usual in England.

One of the prettiest effects is that of the *Arum Lily* (*Calla*) in the garden. It is one of the flowers that improve in the open air; many seem better under glass. In Mrs. Taylor's garden, at a height of over 2000 feet, it was in fine bloom in the first week in March—a large colony, thick in the centre, and then spreading into scattered groups and dots, and finally holding its white vases out of a low hedge near and running a bit into *Holly trees* and under *Pines*. It was a picture of graceful wild gardening.

A winter home of the Rose.—With our *Rose sticks* trimmed in sharp and close till far into the spring, it is difficult to realise the wild grace which some *Roses* show in this isle in winter. They are happy in the south of Europe, but not as here, where they ramble like *Passion-flowers* and bloom as if frost and east wind were banished from earth. One's "scientific" notions of pruning *Roses* get a little shaken in the face of a shoot of *Lamarque* that has gone up "on its own hook" to sun itself on the crest of a *Brazil Araucaria* 30 feet high in the garden of the Carmo Hotel. From the higher windows one sees there a tuft of white *Rose* reposing on the top of the tree—such a *Rose* as one never sees out of doors in England. Major Reeve told me he counted thirty-two flowers and buds at the end of a single shoot of *Lamarque* in his garden near the sea.

THE *LAMARQUE ROSES* in Mrs. Cossart's garden form hedges of such fair and large white *Roses* as we never hoped to see. We have no really good white *Rose* in England, as *Lamarque* grows poorly with us in comparison. Its raiser would be proud if he saw its beauty here. Two trellises of *Roses* border a drive; one is of *Lamarque* alone, and this is nearly covered with full-blown large white *Roses*. The hedge on the opposite side is mixed with green climbers; the *Roses* have not been pruned very close, and the effect is even better here. Near at hand there is a large specimen of the so-called *Pepper Tree* (*Schinus*). Through this to the top there are large snake-like branches of the same *Rose* quite naked and pruned back on the day when hedges of the same kind are so full of flower. Nothing could so well illustrate the value of this climate for *Tea* and *Noisette* *Roses*, of which this is here the queen. The *Pepper Tree* was whitened with blossoms of this fair *Rose* on Christmas Day, and early in the year the great climbing stems were cut in. In such ways it is easy to have several crops of the *Rose* during the winter, and, indeed, *Lamarque* may be had in Madeira nearly all the year round.

CLOTH OF GOLD *ROSE* is no less remarkable where it has a chance. There is a wondrous tree of it in Mrs. Foljambe's garden, covering many yards of trellis-work arching a broad walk, and then running up the *Cypress* and other trees near, showing its flowers here and there through them. Its stem is like a tree; its nobly-formed blooms larger than we have ever seen in any *Rose* in Britain, the form of the flower being superb. Among the shoots on the trellis-work sprouts here and there wreaths of the purple *Kennedy*, contrasting well with the soft yellow *Roses*, and forming a feature new to one from English gardens. *Rosa lavigata*, with its large single blossoms, so fine in form and pure in tone, is as good as either of these double ones. As a hedge bush or bower it is full of flower; anyone who can grow this *Rose* should not be without it. Bushes of it here were more effective from the profusion of the large white cups than were plants of the same size of the white *Azalea*. In the bush form of this *Rose* the long shoots were bound round and round, which served better than cutting them in. We never saw a single *Rose* so fair!

Trees.—The climate is an admirable one for trees, as is shown well in the English cemetery, where there is an old Pepper Tree (*Schinus*), a fine, picturesque object. We had no idea it formed so good a tree when old. Here, too, the large Bamboo is over 30 feet high; and the evergreen Magnolia a tree large and healthy. The Norfolk Island Pine (*Aracaria excelsa*) is also at home here with the Date Palm, the Dragon Tree, which is a native of the island as well as of Teneriffe, and the Eastern Cypress. The Cedar of Goa is common, graceful in all stages, and, when old in a hill quinta, gives a good Cedar-like effect. A beautiful tree is the native Juniper (*J. Oxycedrus*), of which a tall tree in Mrs. Cossart's garden has almost the dignity of a Cedar. The fragrant wood is much used in fine cabinet work by the natives. Old specimens of the Cedar of Goa are broken and fine in form, having a Cedar-like aspect. In the young state it is graceful, and it is much used in all the gardens—an admirable tree for temperate climes. The Cedar of Lebanon does not seem to thrive here.

THE LILY OF THE VALLEY TREE (*Clethra arborea*) of our old greenhouses, now seldom seen, is here a good-sized evergreen tree, 30 feet or more high, and, as may be imagined by those who know it, a fine object in flower at that size. The strong and stout hammock poles used in this place are made from its straighter side branches. The Australian Gum Trees, now being so extensively planted in temperate countries, do well here. They are so often seen in the young and tapering state, that their fine character in the mature one is not much known to European gardeners. Old trees in Mr. Leland Cossart's garden are as picturesque as old Ashes or Birches. Very large, and leaning to the south, they, associated with large *Dracenas*, form a beautiful aspect of vegetation. This garden, at a height of 2000 feet, is rich in sub-tropical vegetation, and has many large Camellias and Australian plants, and the finest Norfolk Island Pines. The altitude, however, is sufficient to prevent many of the plants from thriving which get on well in the ground near the sea.

The great number of trees that may be grown may be judged of by those on Dr. Grabbam's lawn, where the Allspice tree (a beautiful evergreen and large tree with a creamy white stem), the Camphor tree, Coral tree, Sago Palm, Locust tree, and other trees from hot countries grow happily with our English evergreen Oak, the common Tulip tree, the Cypress of Greece and Italy, and the Til and other trees native of Maderia. What might be done in the way of a botanic garden in this island may be judged of in the same way. Probably in no place in Europe could so many species of beautiful sub-tropical and temperate country plants be grown. But public spirit to do anything of this kind does not exist. Interesting as the island to the naturalist is, there is no museum or galleries where specimens of its flora or fauna are preserved for public use, though the getting of representative collections from such a small area would be easy, and result in a welcome and useful addition to the not too numerous attractions of the capital.

Among the low-flowering trees the *Schotias* are curious and beautiful—good and broken in shape, and flowering freely at from 12 feet to 15 feet high—the flowers dark crimson in close bunches below the leaves. The best were in Mr. Hayward's garden. The graceful *Jacaranda*, often seen in our stoves, is here a medium-sized tree, as remarkable for the beauty of its many purple Foxglove-like flowers in racemes, almost covering the tree, as for the elegant Fern-like leaves which it bears in our stoves.

THE BOMBAX TREES in Mrs. Stoddart's garden are superb. Of one the main roots stand above the ground like the backs of great crocodiles covered with spines. Another species has a stem like the mast of a great ship, and the foliage turns a blaze of crimson in autumn. The flowers of these great trees, covered all over with stout, fierce spines, are said to be handsome. The Screw Pines (*Pandanus*) and the handsome *Plumierias* attain fine dimen-

sions in the same place, and there is a specimen of the Coral tree that is common in a small state in our gardens, but here an old and most picturesque tree. The Dragon tree is seen in many gardens. A native of the island, it was once plentiful, but the people destroyed it in getting the sap for dye. Now the last native plant or two may be seen on inaccessible cliffs, and cultivated specimens are very striking in Mr. Selby's and other gardens. At Mrs. Stoddart's one sees the Screw Pines fruiting abundantly with the Maiden-hair tree (*Salisburia*) and the Palma Christi finer than one often sees them in Europe. The Palma Christi was far the largest we have ever seen—a forest tree, in fact.

Fruits.—Among fruits the Loquat is very fertile, and its juice refreshing. Oranges do not seem good. Our markets would take a good deal that could be grown here, and Mr. Holloway has established the culture of Pine-apples on an extensive scale under glass. With this and fermenting material, all the heat required is obtained. The houses are very large, 60 feet in diameter, but the culture did not seem so successful as should be expected under such good conditions. The Custard Apple does well, and the Banana is a common crop everywhere. With such high ground near, the cool country fruits are also grown—the Peach not so well in the low ground, but better on the hills; it is not, however, paid much attention to. The edible Passion Flower fruits freely: it is, as usual, the best of the Passion Flower fruits. Major Bolton finds many of the English Grapes do admirably. Perhaps we may some day see our own Grapes grown for us in countries where fire-heat and glass are not required. He has also made an extensive experiment in silkworm culture, which promises to succeed. The industry had been destroyed in the island through disease. Thinking the failure might be explained by the want of careful and cleanly culture, he made a trial which promises to be very successful and instructive. The *Phylloxera* has greatly injured the Vine in this island; but some American Vines resist the pest, and by regrafting on these, it is believed the evil will be subdued.

The trade that has grown up in Bananas for the London market is already important, and promises to be much more so. The peasants, who used to go round, hat in hand, to find a buyer for their wine, and often failed to do so, are now almost courted for the large bunches of Bananas, for which the demand is greater than the supply. It is a gain in all ways to use the direct products of the earth, and find them more profitable than turning, with painful care and many years of time, Grapes into wine, for much of this was fiery stuff. The dwarf Banana is the kind usually grown, owing to its resisting the winds better than the taller kinds. The rapid steam transit allows of the fruit being sent to London in good condition. The silver Banana, one of the taller kinds, is also grown to a smaller extent.

THE MONSTERA of our stoves, the great leaved plant with the oval openings in the leaf, is an admirable plant here as an ornament, and its fruit is said to be very good by those who ought to know. Our experience of it in England is not favourable; but then the Madeira sun is pretty constant and warm. In any case, the plant is worth growing for its fine form and wholly distinct foliage—in a warm country, admirable for a terrace or in association with stonework; in a cool one, no less useful for the cool house, large fernery, or conservatory, though it is rarely grown in any. It must be planted out and allowed to ramble freely if it is to show its picturesque beauty.

Mr. Leacock made some successful experiments with turpentine and resin in the prevention of the *Phylloxera* ravages, but is now growing a stock of the American Vines, proved to have no attraction for the pest—particularly the Taylor Vine. Grafted on these, the Vines will be pest-proof, though whether there may be any difference in the wine it is too soon to say. Very subtle and apparently trifling changes sometimes lead to important results. The sulphate of carbon was being applied to the Vines at the instigation of the Government, so there are hopes of defeating the *Phylloxera* in

various ways. The idea that the wine of the island is deficient through the misfortunes of the Vine is a mistaken one. The stocks in the island are abundant, and in the stores of the best houses good in quality. It is too commonly supposed that the island wines are not now obtainable, the fact being that there are large stocks of good wine in the island, and that the Grape is grown, and grown successfully, to a large extent. Should the remedies against the *Phylloxera* prevail, there is no reason why it should not be grown as much as ever, but the climate and other advantages of the island point to a much more profitable aim—the growth of fruits and early Potatoes for our markets. The only difficulty would be that as soon as the Government sees any progress made in this way it is certain, judging by present experience, to tax the article exported, and thus destroy the people's chance of a good market for their produce.

The Avocado Pear does well, and so does the Rose Apple and the Mango, of which there is the good Bombay variety. The Custard Apple does admirably; it varies a good deal, and some of the kinds are excellent. The Pitanga is a good small red fruit borne on a low tree of the Myrtle race. The Pomgranate bears well, and Dr. Grabbam praises highly a small species of Guava (*Psidium littorale*) which fruits in a very small state, and is excellent in flavour. It would be worth growing in our hothouses, in which the old small Guava was fruited easily enough.

Vegetables.—A very useful experiment has lately been made here by Mr. Leacock in the growth of Potatoes in winter for the supply of the London market early in the season. In early spring those from Lisbon and the Channel Islands are often very small and poor. Here, in February, tubers of Myatt's Ashleaf were as good as one could desire for any season. Samples being packed for Covent Garden were the best we have seen of early Potatoes. Grown among the Vines, and dug out before the canes bud out, the Potatoes are a catch crop; and this experiment may lead to a profitable industry for the natives. The island has distinct advantages for early crops over the warmer parts of Europe that lie nearer to us, and we hope they may be made the most of, both for the islanders' sake and our own markets—always ready for great quantities of early Potatoes, if large and good, as these are. Peas, which do admirably in the winter here, have also lately been sent to Covent Garden successfully. The quick steamers passing to London from the Cape and calling at Madeira will very much facilitate this commerce.

The *Caladium esculentum* of our stoves and sub-tropical gardens is everywhere grown in moist or irrigated ground as a vegetable, and often is naturalised in the stream beds. It is, when boiled, a vegetable of fair quality—better than an ordinary Potato. The Sweet Potato is much grown, the Demerara variety being the most fertile; three crops are gathered from it in the warmer districts near the sea. Its modest, *Convolvulus*-like flowers, seldom appearing in some other countries where it is grown, are often seen nestling among the leaves. Pumpkins and Gourds are in great variety, and form a great part of the food supply. The Chon-chon is also much grown and used. Tomatoes grow finely, and a supply could probably be sent to our markets. The climate is good enough to allow of the growth of the tenderest vegetables out of doors in winter, Peas and French Beans being then plentiful.

The Flora and the Landscape.

Creeping up the hills one sees everywhere cultivation of some sort, from the Sugar Cane and Sweet Potato to the Vine and the Yam (*Caladium*). The spot not cultivated must be very small and much out of the way. The never-ending attempts to cultivate weary the sightseer, and one doubts while climbing if there is any space left in the island for wild wood or copse. But the Chestnut woods are reached at last, and here and there a carpet of Grass appears, while Pine woods are on the hills, and above them patches of hail and snow on the upper mountains. The scenery so far is interesting and bold, but it is forgotten

in looking for the first time over a grassy ridge or rock into the "grand corral," one of these awful valleys flanked with mountain walls, colossal in their height and terrible in their steepness. Smaller mountains start up in the valley and are crested with evergreen trees far and sheer below us, and there are also arid and castled peaks among them, only stained with broad silver Lichens. Soon we pass on to the mountain country where such scenes are the rule, and much more beauty than one can tell of. The sun is warm above the silver mists that roll up from the sea into the unearthly valleys, levelling them up from time to time, and clear above stands the saw-like ridge of the upper mountains. A desolate hardness and bareness, like that of the Rocky Mountains, is modified here and there as we go on by bushes of the Tree Heath, and soon trees of Laurel-like character are seen, enriching the foregrounds and softening the rocks. In a day's walk from sea to sea, from Funchal to San Vincente, there is time but to glance at the many mountain pictures that are seen when the weather is fair. Como or Tyrol have nothing more remarkable than this island group, though it has not the cold charm of vast fields of snow; the distant purplish ranges, when all is clear; valleys receding into space till the terraced fields are dim afar, and only the bold towered crags that guard them show clear. Much is lost by the grey mists which fill valleys as we pass, but they only take possession of some parts of the country, and we are passing close under a wall of rock a thousand feet high above us, with Fern and bush as abundant as if the slope were soft and easy for soil or rain. Nowhere else do the rocks form such perfect walls; those in the Maritime Alps are severe in their way, but nothing to the Madeiran in their height, length, and danger to the passer-by. In many places the vertical, or almost vertical, crags are embossed with large Houseleeks, and they are rich in silver and gold Lichens which spread into broad patches and finely colour the stone. Owing to the need of passing rapidly to fixed points, it is difficult to see as much of the objects of interest as one would desire. Some large trees of the Til are very picturesque and fine in form. Their main stems are clothed with the Hare's-foot Fern, the finely cut leaves of which form lacework over them.

The poorest of the Irish people seem "bloated aristocrats" compared to men and women occasionally met with in these valleys, yet the Portuguese Government tax them severely, and even have imposts on the importation of their food. The houses they live in are wretched in the extreme—small thatched huts, worse than those the native races in some savage countries live in. The wealthier and more enterprising classes are not let off any easier; heavy and vexatious taxes fall upon them, and the taxes on raw material are such that any enterprise is almost impossible. Miserable as the people often are, however, they show some love for gardening, and every little house has a few flowers, often strange ones for cottage gardens, if we can apply the term cottage to the little houses. Frequently where a wall is used it is hollow in the upper portion and filled with soil, in which flowers and trailers are set—a good plan where people resort much to walls, and this wall garden is called *allegrette*, meaning "a bit of joy!"

The island was clothed with trees to the water's edge, it is said, at one time; but the natives cut the wood without mercy, and are in this way spoiling the land. With plenty of trees on the hills to keep the stream-springs constantly supplied, the fertility of the island would be secured. Take away the trees and shrubs, and the rains rush down to the sea at once, doing harm, perhaps, on their way. In this way we see the harm is done, even if the belief held by some is not true, that the woods attract the rain clouds. The goat is even worse than man in his tree-destroying ways—nibbling off every rising tree, natural or planted. It would be a mercy to remove the goats from many a once fair land they have devastated, as is said to be the case with Greece. Rabbits and goats are the most powerful

enemies of the gardener and planter. One wishes their natural enemies, the wolf and fox, were allowed to clear them off where man himself does not take the business in hand.

The crest of some old Laurel-greened land long at rest beneath the Atlantic, Madeira too was Laurel-wreathed from mountain valley to the shore when the Portuguese first set their feet here; but now all is changed. Richly clad with vegetation then, say, to the shore, the settlers soon seized all the good ground for their crops, cut down the accessible woods, and terraced the slopes of the hills so far as they would yield a patch of ground as big as a kitchen table. The streams and springs were turned from their natural courses from hill to ocean, and guided through cemented little channels to where they were required for the cultivator's wants. Here and there on the faces of the colossal cliffs of the north coast still are seen the long and silvery slender waterfalls, but these will in their turn be absorbed into the irrigating and watering channels. The higher valleys and rocks are, however, still green with the evergreen tree flora of the island and with the rich growth of Ferns it bears. The mountains are very high for so small an island—5000 feet to 6000 feet, and more in one case; and they naturally are embraced by clouds and mists when the low ground is warm in the sun. Ferns, therefore, thrive, and that bold and graceful Fern, Woodwardia radicans, is even encouraged to grow more freely in moist places, so that it may be enjoyed by the cows—said to like it much as green fodder.

Under the trees and in the Grass by the wayside a close turf of short but large Oxalis leaves is formed, and from it in early March many large deep rose flowers are peeping. It is a Wood Sorrel (*Oxalis purpurea*), and a very pest it has proved to the garden-loving folk, invading their gardens and exterminating every blade of Grass on their lawns. It is pretty itself early in the year; but when it fades away, only leaving bare earth and brown patches, then the lawn-maker hates it, and to no purpose, for no human effort seems capable of getting rid of it. By the wayside, too, and often on the margins of the cultivated fields, a yellow Oxalis (*cernua*) is very common, and the double form of it pretty.

In the calm air of our greenhouses some plants have a beauty which they do not keep out of doors, no matter how fair the climate. The old white greenhouse Trumpet Flower (*Bugmansia suaveolens*) is of this class. In some parts of the island naturalised bushes of it take possession, to the exclusion of other things, of the banks of water-courses and moist spots near them. Yet under these circumstances it is never so good in flower as under glass, the flowers being of a duller white. The white Azalea is another case in point. Of many bushes in many varied situations not one seemed pretty—not one so good in effect as an ordinary plant in a greenhouse in full bloom. This is owing to the fact that the bloom, texture, and pure tone induced by the artificial climate of the house help the effect of white flowers very much; besides, the subdued light may suit them better. On the other hand, the Calla Lily looks even better than when protected by a house, and so do many other plants—Agaves, Bignonias, Bougainvilleas, and the various tropical and sub-tropical trees which assume their natural habit in the open air. It is pleasant to meet old favourites that one sees often enough stiff and distorted in a pot forming trees of fine form or bushes of surpassing grace, like our old friend, the Euphorbia, which here bears its vivid wreaths with such a dainty grace.

R.
[We regret that we have been disappointed in the execution of an engraving of a good Madeira garden to accompany this article, but hope to give it at another time.]

Decay in the Willow.—Such is the vitality of the Willow, that decay will often go on for years without necessitating the removal of the tree; indeed, an old Willow forms a picturesque object, and, unlike many other decaying trees, one from which little or no danger need be apprehended from the

falling of dead portions. If the decay has just commenced it may perhaps be arrested by removing the diseased part and cementing; but if hollow, and the supply of sap is maintained by but a small portion of the trunk, it will be well to encourage the still living portions to push out roots. To further this end the hollow portion may be partially filled with soil to serve as a medium for the conveyance of the roots to the ground, and the whole plant should be secured against strong winds, otherwise such old trees are often liable to be blown over. Why cuttings go off I cannot understand, Willows being proverbially easy to strike; perhaps the soil is too hot and dry. All that I do is to cut up the shoots (not necessarily small twigs, but often as thick as one's thumb) into pieces about 18 inches long, and bury them for two-thirds of that length in the ground, when they root and grow away freely.—ALPHA.

GARDEN FLORA.

PLATE CCLXXXV.

COMPARETTIAS.

(With a coloured figure of *C. macroplectron*.)

AMONGST small, yet attractive, plants of popular Orchids the genus *Comparettia* occupies a foremost position, though, like *Ionopsis*, *Burlingtonia* and several other small leathery-leaved epiphytal Orchids, its species thrive but indifferently under cultivation. With us, as with most growers, I believe, they flower well enough the first season after arrival, but to establish and grow them on year after year is not easily accomplished. The treatment under which *Comparettias* have as yet proved fairly happy with us is simple enough, though we seem to be behindhand as regards a proper knowledge of their requirements under cultivation. We grow them on blocks with a little fresh Sphagnum about them, and water frequently during the summer months. During their growing season they are suspended in the East India house, and on the completion of the little growth they make they are placed in a cooler house. It may be that the heat of the warm house is too much for them, yet they do not come to much if one tries them in a cooler temperature—that is, during their growing period. They do not appear to like much sunshine, spot, the deadliest of all enemies to Orchids, being the result of exposure to bright light.

The accompanying coloured plate represents a recently introduced species and one of the most beautiful. Some confusion seems to exist between this species and *C. rosea*, with which it has been stated to be identical. It may be well, therefore, to point out the differences between these two plants, and at the same time to offer a note or two on *Comparettias* generally. That *C. rosea* of *Paxton's Magazine* is abundantly distinct from *C. macroplectron* of Reichenbach there can be no doubt.

C. MACROPLECTRON was introduced in 1878, and named and described in the following year. It is a bulbless species, bearing three or four leaves on each growth, from the sheathing petioles of which the flower-spike springs. The flowers are larger than those of *C. rosea* or of *C. falcata*, another well-known kind, and are characterised by the length of the spur, which is at least twice as long as in any other cultivated species. The lip is broad and squarish, slightly toothed at the sides, and of a pale rose colour thickly marked with red spots, as are also the sepals and petals. It is a

* From a drawing made in Baron Schroeder's garden, The Dell, Egham, in September last.

very pretty little Orchid, and being a free flowerer is likely to become a favourite. I saw a good specimen of it in flower at Kew a few weeks ago.

C. ROSEA.—Although quite distinct from C. macroplectron, this kind seems so near the older C. falcata, that I suspect the one is most likely a variety of the other; and as the latter name has precedence over Paxton's, I suppose the name rosea will have to be dropped, or at least exist only as a varietal name.

C. FALCATA has smooth, oblong, clustered pseudo-bulbs, sometimes sheathed with brownish scales. The foliage is thick and smooth, rather leathery in texture, and borne singly on each bulb. The flower-stalk is about 12 inches long, and bears from 3 to 6 rich purple or crimson flowers with spurs about 1 inch long.

C. COCCINEA has oblong channelled bulbs, the young ones being covered by the sheathing bases of the three or four leaves which are borne on each bulb. These leaves are narrow, about 5 inches in length, of a leathery texture, and the underside is of a purplish colour. The flowers of this species are very prettily marked, the sepals and petals being yellow edged with red, and the lip entirely of the latter colour. This species is rarely seen in cultivation, being rather difficult to manage, and, moreover, not by any means plentiful in its native habitat.

C. SPECIOSA.—This I have not seen. Reichenbach describes it as being very beautiful, quite comparable with C. macroplectron. It has even been compared with *Oncidium concolor*. At Burford Lodge I believe the first flowers of this plant in this country were seen, and it is said to have quite come up to the expectations formed of it from the collector's description. The colour of the flowers is as follows: Sepals and petals light orange, the base of the labellum being of the same colour, while the blade is cinnabar. These flowers are borne ten on a spike, and as they are described as large and showy for the genus, the plant must be a very desirable one. As far as I know, few if any plants of this species are in cultivation now.

B.

SINGLE-HANDED LAWN MOWERS.

HAVING used many of the old machines, and also the majority of the newer forms which have been brought out from time to time, including the Archimedean, Excelsior, Climax, Coventry, and others of a like class, I most unhesitatingly give the palm to the Excelsior in its four-bladed form for easiness of working, quality of work, ready adjustability, and durability, and also for cutting either short or long, wet or dry Grass. During three years of constant work one I used cost only about 2s., which was for oil, of the quality of which I am very particular. A boy of twelve can easily use a 14-inch Excelsior on any ordinary lawn, and a 16-inch machine runs as light as the ordinary 12-inch machines with the old-fashioned cutters, and the handles being adjustable can be raised to suit any height, thus applying the maximum of power with the minimum of fatigue. Three 14-inch machines worked by three boys of fifteen or sixteen would do more work in a stated time than two of "J. D. B.'s" 28-inch machines worked by six men, thus effecting a great saving and doing the work equally well. I might incidentally mention that last year at the Chertsey Flower Show, held in Oatlands Park, the local agent asked me to exhibit for him, as he was not up in that class of work, and both on the first day, when the rain fell in torrents, and on the second day of the show, both 14-inch and 16-inch machines cut Grass 4 inches or 5 inches high under trees, the bottom being very rough and uneven, and many gardeners who saw the work and tried the machines expressed themselves satis-

fied with the work done and with the lightness of draught of the machines. I should recommend "J. D. B." to try the Excelsior before purchasing, because if not pleased with it after a reasonable time it can be returned, and without any expense whatever to him.—W. J. MAY, *Walton-on-Thames*. [Other letters in favour of this machine have also reached us.]

—I think "J. D. B." (p. 282) cannot do better than purchase two 14-inch Barnard, Bishop & Barnard Lawn Mowers. I have had nineteen years' experience as a gardener, and have had all sorts of machines to deal with. I do not consider any equal to theirs for several reasons; first, one can sharpen the cutters one's-self with a little oil and emery paper, and by turning the cutters backwards, for which a handle is supplied. Next, the rollers are heavier than usual; consequently they run steadier, and the cutters go deeper, and take a better grip than those of other machines.—T. M., *Bolton*.

—"J. D. B." is quite right in his opinion that two men with 12-inch lawn mowers would do more work than three with a 28-inch one, and would be less fatigued. We feel sure if the "Invincible" were tried, the operators would derive every satisfaction from its use.—JOHN CROWLEY.

SEASONABLE WORK.

FLORAL DECORATIONS.

ONCE more we have from hardy shrubs and trees a good supply of flowers that are useful in a cut state. A useful early flowering plant is the double blossomed white Peach, which looks exceedingly well against a background of common Laurel. In a cut state it will look well with the golden yellow *Kerria japonica*. The foliage of *Berberis Aquifolium* would no nicely as a background for an arrangement of this kind. *Pyrus japonica* and its white variety make a nice change. When using these flowers secure a few fresh green growths also, to arrange with them. The early flowering hardy *Rhododendrons* are always valuable. Like the *Pyrus*, these arrange best by themselves. We find three or four trusses of two distinct colours of these hardy American plants to group well together for a sideboard decoration. Besides all these there are *Laurustinus*, *Ribes sanguineum* and its white form, and other shrubs which, for cut purposes, ought to be more valued than they are; and where a supply can be thus got, as at the present time, from the open air, less pressure should be put upon that from the houses. Of hardy bulbous plants, the Bluebells (*Scilla campanulata* and *patula*) are valuable aids in floral decorations. A few spikes look pretty arranged with *Hoteia japonica*, or in a dinner-table arrangement they associate well with the Amazonian Lily. Of plants easily grown under ordinary greenhouse treatment, *Choisya ternata* is a valuable shrub, as are also the *Eriostemons* (*E. linearifolium* in particular). We have these in flower now, the latter plant being in that condition nearly all the winter. Both of these shrubs are most valuable for bouquet work. A few pots of Musk will be an agreeable change in the house where this plant has been forwarded; so also will early Stocks and small plants of *Heliotropes* and forced Pinks, not forgetting *Mignonette* from autumn-sown seed.

FLOWER GARDEN.

WALLFLOWERS, Primroses, and Polyanthus may be sown now, and good varieties of the two last should be increased by division as soon as they have done flowering. New plots of Violets should be made as soon as runners can be had; from these early plantings good flowers are frequently produced in quantity throughout the autumn and winter. The Czar and Victoria Regina are the best winter bloomers, simply because they are the hardiest. In order the better to insure a long succession of flowers in spring different aspects should be chosen. We plant a few at the foot of

the fruit tree walls in every aspect; from the south we gathered quantities of blooms in January, and from the north and east aspects they have not yet done flowering. Lily of the Valley is amenable to the same mode of culture, and the season of flowering is also proportionately extended. Beds of this Lily should now be top-dressed, and new beds made by dividing the roots that have been forced. Plant single crowns in lines 9 inches apart and 3 inches asunder in the line; press them firmly into the soil, and then mulch with cow manure, which should remain on the whole of the summer; next season some good flowers may be expected, and the following one they will be as fine as those from imported crowns.

GENERAL WORK.—This, to a large extent, still consists in the preparation of plants for summer arrangements. We are at present busy making up hotbeds, consisting of stable litter and lawn mowings, for *Alternantheras*; putting in cuttings of *Mesembryanthemum cordifolium variegatum* in boxes, which are placed over the pipes in vineries to strike; pricking off seedling *Tagetes*, *Pyrethrums*, *Zinnias*, *Asters*, and *Stocks*, also potting off *Coleuses*, *Iresines*, *Heliotropes*, and *Petunias*, and planting out *Lobelias* and *Verbenas* in turf pits, and *Calceolarias* and *Violas* in the open air. Dahlias and sub-tropical plants require the extra space thus gained, and some of these need larger pots, our rule being never to let them get root-bound, as that cripples the growth of the plants for the whole season. The outside operations now are principally mowing and sweeping; preparing beds and borders for planting; pruning and tying up, or nailing in climbers; sowing hardy annuals, and making successional sowings of Sweet Peas, *Mignonette*, and Virginian Stocks; weeding, and in mossy places, salting walks and roads.

INDOOR PLANTS.

STEPHANOTIS AND GARDENIAS.—Plants of these two fragrant white flowers started in a brisk heat some time back will now come rapidly forward. The *Gardenia* is a sun-requiring plant, as however much heat it receives the flowers do not make much progress until the sun gets some power. Use every means to keep down scale and mealy bug which will now increase apace. If the growth of the *Stephanotis* was well ripened last autumn, the plants will generally show flower freely on the young shoots as soon as formed. Do not use too much atmospheric moisture, as where subjected to an over-humid atmosphere, the bloom is usually proportionately deficient.

PERPETUAL FLOWERING CARNATIONS.—Where there is a well-managed stock of these, the principal lot should now be fast pushing up their flower-stems, for, although from their perpetual blooming habit with a sufficient number of plants their flowers may be had all the year round, still they come much finer and in greater abundance during the spring and summer. The plants will be much benefited by the application of manure water once a week. This will not only assist the earliest flowers, but also the successional bloom. A little soot added to the manure water will be found an advantage, as besides its manurial properties, it tends to banish worms, and there is no insect that appears to like depositing its eggs on plants that have the odour of soot about them.

TUBEROUS BEGONIAS.—If not already started, the old bulbs of these should at once be set to work, repotting them in good, fresh soil, and giving root-room proportionate to the size of the bulbs, for though they may be considerably assisted by liquid stimulants, yet with free-growing subjects like these Begonias, that form large heads in little time, a good amount of space is requisite for the roots; if too much confined, the amount of growth and flowers forthcoming will be limited.

TENDER ANNUALS.—Even in gardens where plants of a permanent character are made the principal feature some of the handsomest annuals suitable for pot culture may be grown with advantage. Such things as Balsams, Globe Amaranthus,

Rhodanthe Manglesi, *Celosia pyramidalis*, and the old-fashioned Cockscomb, when well managed, are amongst the most effective plants that can be grown for summer decoration, and when in flower they can be placed about in conservatories and similar structures where it would not be expedient to set plants of more value. The feathery plumes of the *Celosia* are unequalled as regards effect when grouped with plants of more bushy habit. The principal matter to be kept in view in the cultivation of these things is to give them sufficient room and keep them close to the glass from the time the seed germinates until they are in bloom. It is not advisable to place the seeds in too much heat; an intermediate temperature, such as that obtainable from a moderate hot-bed composed of leaves and manure in about equal quantities, answers best. Pits or frames now occupied with bedding plants will in most places be at liberty in a short time, and will be available for them in their subsequent stages.

LINUM TRIGYNUM.—Where yellow flowers are prized, combined with a plant that occupies little room, this old-fashioned Flax is deserving of cultivation. If seeds of it are sown at once they will make nice blooming plants before autumn. It is somewhat liable to the attacks of red spider; consequently a constant use of the syringe will be necessary, dewing the plants over every day. 6-inch or 7-inch pots are large enough, stopping once or twice to induce a bushy condition.

LISIANTHUS RUSSELLIANUS.—This deserves a place wherever there is the means of giving it intermediate warmth, as so treated it does much better than where it receives more heat. The seed should be sown on the surface of the soil in a pot, covering it little or none, with the exception of a piece of glass, which should be placed over the top of the pot. The latter should be set in a pan containing a little water that will be absorbed by the soil, thereby obviating the necessity of watering overhead, which displaces the seeds and retards their vegetating. It is biennial in habit, plants raised from seed sown now blooming in May, June, or July the ensuing year.

TODEA AND TRICHOMANES.—Many who have attempted the cultivation of these elegant Ferns have failed through keeping them too warm. No heat is required, except simply to keep out frost. They require to be confined within a glazed case, for though they will live exposed to the atmosphere of an ordinary cool fernery, yet they do not get on so well as if less air was given them. Any that need more root room should be repotted, being careful not to disturb the roots more than is unavoidable, as now, when growth is commencing, any mutilation of them will interfere with the development of the young fronds. Keep the soil well supplied with water, as the least approach to dryness is most injurious at all times, but much more so during the early stages of growth than at any other time. In giving water be careful not to wet the plants overhead, as if this is not avoided they always have a brown, shabby appearance.

LYGODIUM SCANDENS.—Where large stands or baskets are required to be filled with flowers this climbing Fern should be grown in sufficient quantity to admit of its being used freely, as its elegant long sprays have a beautiful effect when entwined amongst flowers and other green foliage.

FRUIT GARDEN.

VINES.—By this time the Vines in the latest houses will be fit for stopping if the operation has not already been performed. Syringe well twice a day until the branches become prominent, encourage a short-jointed, sturdy growth by ventilating freely through the early part of the day, close with brisk sun heat to save firing, and allow the temperature to range about 60° at night. If the inside borders have not been watered since the Vines broke, now will be a good time to give them a thorough watering—if gross, with pure water;

if weak, with liquid or guano added—which will carry them on until after the fruit is set, when they may be again watered and mulched with short manure. Pay regular attention to daily details in succession houses, and on no account let the thinning of the berries get behind, otherwise a tedious operation of this kind, which requires great patience, is sure to be hurried over and imperfectly performed. Fertilise Muscats now in flower, also Black Morocco and other shy-setting kinds, using Hamburgh pollen if it can be obtained or has been preserved in a dry, warm place. A camel's-hair brush should be used in preference to drawing the hand down the bunches, and the atmosphere of the house should be dry and warm when the operation is performed.

Examine the foliage in out-of-the-way corners in the early house, and if a suspicious-looking leaf is found, either sponge at once with weak tobacco or soap water, or apply the usual remedy to the pipes for the destruction of spider. At the same time look well to inside borders, and if found dry, a condition under which spider makes rapid strides, water freely with guano water and mulch with short stable manure which has been well worked as for a Mushroom bed. Damp this frequently to keep the atmosphere charged with moisture, maintain a low night temperature by giving front air, and, most important of all, see that the Vines are not carrying more fruit than they are likely to swell up and finish. Many people overcrop and suffer, but we never hear the grower or the consumer complain when a moderate crop colours and ripens well.

GRAPE ROOM.—The dry atmosphere which prevailed throughout the past month was favourable to the keeping of late Grapes in rooms not affected by sudden changes of temperature, and such kinds as Gros Colmar and Alnwick Seedling are still fresh and plump. The last named being the first to break in the spring, and the first to ripen when grown with such varieties as Lady Downes, Alicante, and Mrs. Pince, and its quality being so good, the proof that it is a good keeper will at once stamp it as one of our best spring Grapes. It will now be necessary to keep the room as cool as possible, by admitting a constant circulation of air and keeping the shutters closed all day, as light and sun heat will begin to have an injurious effect upon the colour and texture of the berries. Keep the bottles well filled, remove all decaying berries, and keep down dust by occasionally washing the floors with warm water in fine weather.

PEACHES AND NECTARINES.—The most trying and critical period in Peach culture is the stoning process, which lasts about five weeks, and so great is the strain upon the trees, that during that time no outward change is perceptible in the size of the fruit, but good work is going on within, and as soon as the old lime rubble, so often recommended for Peach borders, has been converted into bony foundations for the luscious pulp, the last swelling for ripening will be very rapid, and forcing may be pushed on under a much higher temperature than would be safe through any of the preceding stages, but it must be borne in mind that hard forcing is not recommended, as trees placed under high pressure are short-lived, and the fruit they produce is generally small, flavourless, and deficient in colour. To have the fruit fine and well coloured, low temperatures, ranging from 45° at the commencement to 58° at the finish, with a free circulation of air on all favourable occasions, are points which must have attention, and where they are neglected the mediocre fruit so frequently met with will be the result. Having kept the trees regularly syringed and ventilated to prevent fluctuations through the stoning period, the first sign of a move forward will denote the time for the final thinning, an operation upon which many fruit growers disagree, one man asserting that his trees carry twelve fruit to a foot, while others, myself amongst them, find one good Peach to every square foot of trellis covered with foliage is a heavy crop for trees to carry for a number of years in succession. Pinch the points out of all growths which will be removed after the crop is gathered to throw size into the fruit.

Tie down the young shoots where a free and easy style of growth has been adopted during the stoning process, and elevate the fruit well above the foliage, point upwards by the use of short pieces of lath placed across the trellis. Give another watering to inside borders, and mulch well to keep the surface roots moist and active during the time the fruit is ripening. If soft water cannot be obtained for syringing, water free from lime should be used, otherwise the sediment will mark the fruit and detract from its appearance when ripe. Follow up the usual routine in succession houses and keep everything in order by the timely performance of the various operations now crowding upon each other. Disbud, tie down the shoots, and thin the fruit in late houses. Use the syringe freely all round, and give all inside borders copious waterings with water at the mean temperature of the houses in which the trees are growing.

CHERRIES.—When the fruit in the early house is set, daily syringing must be resumed, and continued until the stoning process is complete. In the meantime the stopping of superfluous shoots to form spurs, and the tying-in of others where young wood is needed, must have attention. As days increase in length and the sun gains power, the temperature with a circulation of air may range from 50° to 60°, and a few degrees higher after closing with solar heat; but it will not be well to make much advance on the minimum temperatures given the other day, say 45° at night, unless the weather is very mild, when 50°, or perhaps more, may be maintained without having recourse to fire-heat. Keep all insects in check by timely application of the usual remedies. See that the roots are well supplied with water, and have the surface well mulched to prevent the escape of moisture when the fruit begins to ripen.

FIGS.—Favoured by a tolerably good season, the most forward fruit on pot trees will soon begin to ripen, when watering may be gradually reduced, but at no time must the trees feel the want of water, neither must syringing be entirely discontinued, otherwise spider will speedily follow the check and give much after trouble. From this time forward the house may be freely ventilated in favourable weather, and the temperature may range from 60° to 65° at night and 70° to 75° by day with a rise to 80° after closing on bright afternoons. Maintain a circulation of warm air through the night. Keep the young growths neatly tied down to give the ripening fruit the full benefit of light and solar heat, and as ripe Figs can be kept for a few days laid on a hair-sieve in a dry room, make a point of gathering all that are ready at short intervals, and immediately give a good watering with tepid liquid, and syringe copiously to help forward the advancing crop. In succession houses where the trees are planted out, pinch or remove the side shoots and tie down leaders to prevent overcrowding, but do not stop the latter until they have reached the extremity of the trellis, as the Fig, unlike many other kinds of fruit tree, keeps producing a succession as long as it continues growing. In some parts of the tree stopping is quite necessary to prevent the fruit from being too much shaded by the foliage, but stopping should not be practised after the turn of the summer or when the trees are weakened by forcing and unable to push young growths from the eye nearest the point at which the shoot has been stopped. Trees in late houses may now be well syringed and watered to help the crop along; ventilate freely to insure a firm, short-jointed growth, and close early with sun-heat to save firing through the night. Examine spring-struck cuttings, and shift them on as they require more pot room. If kept in or over bottom-heat with their heads near the glass, they may be got into 12-inch pots by the autumn, and strong enough to bear fruit next year.

STRAWBERRIES.—If these plants still occupy shelves in Peach houses and vineries, lose no time in getting them removed to safer quarters, and thoroughly cleanse the houses or the parts in which they are likely to have left the nucleus of a colony of spider before it has time to extend to

the permanent and more valuable occupants, where it will do more mischief than the Strawberries are worth. If a hot-water pit, in which the plants can be placed near the glass, is available, this will be found the best place for their reception, as there they can be copiously syringed and shut up early with sun heat to swell the fruit, and the pots being less exposed to bright sun and draughts of air, feeding can be more effectually and economically carried on than when elevated on shelves in lofty houses. By this time the stock will have been reduced to the late kinds occupying 7-inch and 8-inch pots, and as these will now be making an abundance of foliage and throwing up their flower-scapes, see that they have plenty of air and water, and syringe well when the pit is closed for the day. If the plants have not been disturbed since they were stored away in the autumn and space is available, a general turn over and partial replunging, giving the best more room by turning out the weakest to form a later batch by themselves, the crop will well repay the time and trouble expended upon them. Let the crows be examined as the work proceeds, and correct any derangement that may have been caused by worms; also ram the soil well back to the sides of the pots to insure the even passage of water, and top-dress the surface with a mixture of rich loam and rotten manure. To secure extra fine fruit, thin off weak blossoms before they open, fertilise those left when ready, and tie up to light sticks when they begin to swell.

KITCHEN GARDEN.

OF Celery, which is always useful and enjoyable when well blanched and well grown, our early sowing now pricked on tin boxes for the second or for the main crop is well above ground; for the last crop of all we sow in the middle of this month; this proves most useful for soups in early spring. Early Broccoli, such as Veitch's Autumn Giant, good old Walcheren, and White Cape should, if not already done, be sown at once—under glass if possible. To sow seeds outside is not a good system; the young seedlings do not grow and flourish in the same manner as if raised under glass, and weakly, crippled plants are not the thing if success is a consideration. Defer sowing the later kinds until the 1st of May. Scarlet Runners we grow in miniature trenches, the same as Peas; the trenches should be taken out at once, well manured, and dug deeply, breaking the soil well as the work proceeds. We then put an inch deep of burnt refuse on the top of the broken soil, and wait until the second week in May; then with a cultivator we mix the ashes and the soil in the trenches, draw a shallow drill down the middle, and in this plant the Beans, in single rows, earthing, them up, when large enough, until the ground is level before staking. This method of planting Scarlet Runners makes them to a great extent independent of dry, hot weather. Peas that are sufficiently grown should be staked after slightly earthing them up; and here we must remark that Peas are very much benefited by staking; it keeps that worst of all enemies—the surface wind—at bay. We consider wind far more dangerous than frost for all outside Peas. Our earliest Pea, Ring-leader, is showing flower, but we have Minimum in pod, grown in boxes under glass, no fire-heat being used. We are just finishing planting Potatoes, for which the land is in fine condition and the weather perfectly glorious; therefore, if these two important matters have anything to do with raising good crops, we venture to prophesy that success is certain. We have just begun to cut spring Cabbages; they are not large, but fairly solid, and good in flavour. Hicks' and Black-seeded Brown Cos Lettuces, both good winter varieties, we have been cutting for use all winter, and just now we have a very good supply. Hicks' Hardy is the best so far as colour goes. Tomatoes grow apace just now. Keep the side shoots thin, and supply them with water abundantly, but nothing more at present. When a good crop is well set, treat them to a little manure water, but not

too much—1 quart of manure water to 3 galls. of clean soft water. French Beans should now be sown in small pots, and planted out under south walls or in warm corners for an early supply outside.

PUBLIC GARDENS.

THE YELLOWSTONE PARK.

THIS Great Northern Wonderland, according to the *New York Tribune*, is just now exciting lively public interest. Hemmed in by mountain ranges whose crests glitter with perpetual snow, the marvels of this volcanic basin were unknown until within a few years, and although Congress wisely set it apart and dedicated it to the people as a park for ever, it has been so remote and inaccessible that comparatively few visitors have yet explored it. Last autumn, however, General Sheridan reported that too many tourists and hunters had been there already, and that the work of defacing the park and killing the game had been most industriously prosecuted. It was recommended that an added area of forest land should be embraced within the park boundary as a game preserve, and that the whole be policed by the army to prevent further depredations. General Sheridan's report occasioned some discussion, and people began to think how their priceless possession might be preserved. For this purpose a company of gentlemen has been incorporated under the title of the Yellowstone Park Improvement Company. It covenants in its proposed lease to protect the park from marauders. Some provision for the comfort and entertainment of visitors to the park will be needed, and preparation for this purpose must be made too within the park, for its present boundaries contain some 2500 square miles. But of course great caution should be exercised in granting exclusive privileges. The first thing to be cared for is the park itself. The elemental forces which made the world here display themselves as they are not manifested in any other part of the earth's surface. The scenery, too, has a unique impressiveness, as if some distinct preparation had been made for this heart of the continent, from which water flows to the Gulf of California, the Pacific, and the Atlantic through the Gulf of Mexico. The preservation of this wonderland as it is, in all its original grandeur, should be the prime condition exacted from any or all who are granted privileges from the Government. And this protection should mean more than simply guarding the forests from fire and the geyser cones from being battered down. The danger from "improvements" is quite as serious as any threatened by the wantonness or thoughtlessness of visitors. The most sublime scenery, when scarified by a brutal engineer, may lose all its impressiveness, and the obtrusive ugliness of some misplaced hotel can disfigure the noblest landscape. Not a road should be graded nor a single structure erected in Yellowstone Park until plans have been submitted to some artist of recognised taste. Provision against the vulgar intrusion of distracting and incongruous objects should be another condition in any lease of park privileges.

Preservation of open spaces.—Miss Octavia Hill has done well to call attention to the fact that the North-Western Additional Powers Bill, just coming before a Parliamentary Committee, proposes to absorb one of the only too scarce open spaces of the metropolis, the disused cemetery lying between the Euston Station, Hampstead Road, and Little George Street. Now is the time for public opinion to make itself felt in the matter. We know by sad experience how these things are done. A company makes out a good case—public interest, of course—for taking or spoiling some little bit of ground not yet covered with houses. The people injured by such a course have no real power of making their opposition felt. They cannot afford to make a counter offer. Most of them are but half conscious of the importance of the matter, especially if, as in the present case,

the place is only a disused burial-ground. The Board of Works offers a lame opposition, but makes no effort to obtain the assistance of an efficient public opinion. Judgment practically goes by default against the inhabitants of the neighbourhood. Next year the ground is covered with coal-trucks, or it may be an engine-repairing house, and one of the lungs of that district is gone for ever. The maintenance of even the smallest open space in the midst of our teeming population is a matter of supreme necessity. The fact that the ground is at present disused makes no difference. If not used now it may be used hereafter, when the need will be even greater than at present. Besides, open spaces, even if closed, are invaluable as reservoirs of purer air than that of courts or alleys. The question, indeed, is too clear for argument; and yet perhaps Londoners will never be able to protect themselves against these encroachments until such purely local questions are left to be decided by a local representative body.

Park at Versailles.—It is to be hoped that the French authorities will soon do something towards the restoration of the roads, ornaments, and plantations of the park at Versailles, which is falling into a pitiable state of desolation and decay. The masonry and statuary are broken in many places, and the latter are blackened with damp. The trees and turf are neglected, and weeds and underbush choke up the once trim glades. The roads, particularly during the recent wet weather, have been in a frightful state, and altogether the once lovely park presents a melancholy spectacle of ruin and neglect.

Mitcham Common, a lung rather of Croydon than of London, is in danger of being annihilated by the speculative builder and the lord of the manor. A local committee is endeavouring to contest the rights of the aggressors, but can only raise £600 for that purpose. They, therefore, the other day presented a petition to the Corporation of the City of London for their assistance. It is to be hoped that the City will give it in this case as they have done in many others; but it is rather anomalous that the borough of Croydon should be unable to help its 80,000 inhabitants in this matter.

FRUIT GARDEN.

TEMPERATURE FOR FORCED VINES.

UNTIL I opened THE GARDEN last week I thought I had read enough of "Peregrine's" writings to convince me that he was not a stickler for hard and fast lines; but I must confess that he has disappointed me in this matter, as a reference to his remarks (p. 285) respecting the night temperature that Mr. Barron recommends for early forced Vines will show. He makes a difference of 5° a subject worthy of special note, which, to me, looks something like hair-splitting. As regards the night temperature for Vines started in November, allow me to tell "Peregrine" that we have here an early vinery that has been forced for fourteen consecutive years. To this house we always begin to apply fire-heat in the middle of that month, and my rule is from the first to keep the temperature at 60° both night and day until the Vines have broken regularly from one end of the rod to the other. The night temperature is then reduced to 52°, and the day temperature increased to 62°. At this point it remains until the Vines commence to bloom, when the heat is increased 10° both night and day. These figures, it may be well to state, apply to fire-heat only. A range of 10° to 20° is always allowed for sun-heat. It seems to me that "Peregrine" has not sufficiently taken into account the time of year. Starting Vines in November is very different from doing so in the middle of March. Vines will not only bear from 5° to 10° more heat to get them to move in November than in spring, but they will take from two to three weeks longer to break. The question of a fortnight does not seem much as regards breaking, but it makes all the difference at the time when the fruit should be ripe, and

unless this is understood the inexperienced might be considerably inconvenienced by being thrown a fortnight out of their reckoning. According to my experience no one can go wrong who has to start Vines in November if they commence with a temperature both night and day of 60°—that is, assuming that there has been a preparatory process, which every good gardener would of course be sure to carry out. In order to make this more apparent, let me describe the way in which I treat our early Vines. They are pruned in the middle of September, and I always prune to the best bud, which is generally the third or fourth from the spur. The most prominent bud is not necessarily the best; the bud most likely to yield the best shaped bunch is that which has matured an ordinary sized leaf; the buds to be avoided are those that have produced the smallest leaves near the spur, and the largest, which are generally about the fifth or sixth from the spur. The Vines are then let down from the wires and laid upon the border. At the end of October we give the rods a dressing of nicotiae soap; all the glass and woodwork are also well scrubbed with warm water, the pipes are painted with lampblack and oil, and the walls whitewashed. The house is then shut up close, and remains so through the fortnight preceding the middle of November when actual forcing is commenced with a temperature, as I have said, of 60° both night and day. I do not say that my practice differs in any material degree from that of others; nor do I claim to have better results. I have merely given these details to show that even in Grape culture hard and fast lines are not always the best; and in

FORCING POT VINES I have many times proved that when the Vines have been thoroughly ripened and hardened by exposure to the open air, it is necessary to increase the temperature after the first fortnight to 65° in order to induce them to break in a stated time, nor has the crop suffered in any way from this temperature. The great secret is to reduce the heat to a safe point as soon as the buds have made 2 inches of growth. In cases in which it is immaterial whether the Grapes are ripe by the middle of May or the end of that month, slow forcing is all very well. Under both systems good Grapes are obtainable where the requisite degree of skill is brought to bear upon the work, all other things being equal.

C. J.

Top-rooted Vines.—With reference to my note on this subject in *THE GARDEN* (p. 251), my attention has been called to the fact that the writer's notes, which "Peregrine" (p. 209) supposes to have reference to double or top rooting, will not bear such a construction, and though when I first read them I myself so interpreted them, on closer examination I must acknowledge that I was in error. The writer does not allude to double rooters at all, but simply to the tops of Vines that had been cut off at the winter pruning, and which he proposed to layer in the border in exactly the same way as are our double rooters, hence the error.—*W. WILDSMITH, Heckfield.*

The Musch-Musch Apricot.—The middle of April is, of course, too early to speak decisively about the Apricot crop in general, but not too early to speak of the behaviour of this particular variety in connection with the circumstances as regards weather through which it has lately passed. Even in Somerset Apricot trees have felt their full share of the late inclement March, for coming, as it did, in its worst form just as the trees were in full blossom, they have suffered to a degree not experienced for some years past, with the exception of the Musch-Musch. The particular tree to which I allude, though treated in no way different from the others, if so well, is bristling with young fruits on every branch; indeed, so thickly are they set, that we shall have to remove quite two-thirds of them. This we shall be glad to do, for the fruit on the Moor Park variety is so far apart that we shall be glad of the thinnings from the Musch-Musch to send to the kitchen as green fruit. It appears to me that the Musch-Musch is a much

hardier variety than the Moor Park, but that, unfortunately, is about the only merit it possesses; in no other way is it equal to the Moor Park, for it has a large stone, and the flesh is thin and not of the best flavour.—*J. C. C.*

WEIGHTS OF SMOOTH CAYENNE PINES.

I AM surprised that the Smooth Cayenne Pine is not more extensively cultivated in this country than it is. In my opinion it is the very best variety in cultivation at the present time. The following two lists represent the production of two separate pits of this Pine grown without any bottom-heat, except that supplied by a bed of leaves. I have grown this variety for more than thirty years, and during that time I have not missed many months without having ripe fruit of it fit for table. I therefore consider it a most useful Pine both for early and late fruiting.

HISTORY OF GRAPES.

THE ABERCAIRNEY AND WHITE LADY DOWNES GRAPES—It is very desirable that the history of cultivated Grapes should be correct; therefore allow me to furnish you with some particulars regarding the Abercairney seedling, which I see is classed in "Vines and Vine Culture" as synonymous with West's St. Peter's, which hitherto has never been regarded as the same. I was familiar with the Abercairney seedling growing side by side with Oldacre's West's St. Peter's, at Drumlanrig in 1855 and 1856 in the late vineyard there, and the two were totally unlike. I understood also that the Abercairney variety was raised by the father of Charles and James McIntosh, respectively of Dalkeith and Drumlanrig, and if I remember correctly it was Mr. James McIntosh who told me this. It is also called Moray's Grape, probably because that is the name of the owner of Abercairney. I am very well acquainted with the West's St. Peter's, and regard Mr. Barron as mistaken in the matter. I think the Abercairney Grape was lately described by one or more correspondents of the *Chronicle* (Mr. Gilbert, I believe, was one), and the description given of it there was not that of the St. Peter's, but more like what I remember the Abercairney to have been like. As to the white Lady Downes, I have always understood it was a seedling from the black sort of that name, not crossed by any other kind, and in Burbidge's "Cultivated Plants," where the history of the variety is furnished by the raiser of it himself, it is so described. It is a pertinent question to ask, therefore, where did Mr. Barron discover its Muscat of Alexandria parentage? which it does not resemble in any respect, ranking next to the Gros Colmar as regards flavour.

CANNON HALL MUSCAT GRAPE.—"Vines and Vine Culture" says of this Grape that "its origin is uncertain;" that "the earliest trace of it is at Cannon Hall, Yorkshire." The facts are that the history of the Grape is well known, and the traces of its existence at Cannon Hall have always been of the most visible description. I have seen the very large, old Vine at Cannon Hall a great many times. Mr. Wilson, who was gardener there for about thirty years, told me it was the original Vine, and he found it there when he went from Claremont, where he was foreman to Charles McIntosh some forty years ago. This old Vine, being feeble, was done away with a few years ago in the course of alterations in the garden, but one of its progeny, nearly as old and large as the original, is still there and looking well. I saw it a week ago. It has a stem about as thick as one's leg at the base, and the rods are about 35 feet long. Another vineyard is planted exclusively with it, and the plants look remarkably well, all showing fine bunches. The Vine is regarded as a kind of heirloom in the family, and Squire Stanhope, or his present gardener, Mr. Clark, could, I daresay, give all the particulars of the Vine's origin and history at Cannon Hall, and which has never been disputed.—*J. S. W.*

Black Prince Strawberry.—I am pleased to see "H." (p. 319) speaking so well of this variety, and including it as one of the sorts worth growing. In my opinion it is decidedly so, and were I compelled at any time to confine myself to one variety of Strawberry, Black Prince would be the one. For forcing under glass or for growing in the open air there are no other kinds so early or so prolific, and few, if any, are better flavoured. Here it is ripe at least twelve days before any other sort, and by growing some of the plants on an early border and others in a late position it is surprising the succession of fruit which may be had from it. When well cultivated many of the berries become as large as those of Keen's Seedling, and it is the deepest coloured of all Strawberries. In bright, sunny weather the fruits are almost black and the flavour peculiarly rich. For preserving it is especially well adapted, and I am surprised that those who grow Strawberries for market do not have a large quarter of it. In some years I have seen it reported that Strawberries were 10s.

per pound in Covent Garden. These must evidently have been forced fruit, but at the same time we had abundance of Black Prince ripe in the open air, and this could have been sold at the time with a good profit at half that price.—J. MUIR.

GARDEN DESTROYERS.

THE RED SPIDER.

(TETRANYCHUS TELARIUS.)

THE red spider is not correctly speaking an insect, though it is commonly spoken of as such, neither is it a spider, as its name would imply, but an acarid or mite. Whether its name is correct or not, it is a most destructive and troublesome pest wherever it makes its presence felt; it by no means confines itself to one or only a few kinds of plants, as many insects do, but it is very indiscriminate in its choice of food, and it attacks both plants grown under glass and those in the open air. When these pests are present in large numbers the leaves on which they feed soon present a sickly yellow or scorched appearance, for the supply of sap is drawn off by myriads of these little mites, which congregate on the undersides of the leaves, where they live in a very delicate web, which they spin, and multiply very rapidly; this web and the excrement of the red spider soon choke up the pores of the leaves, which, deprived of their proper amount of sap, and unable to procure the carbon from the atmosphere which they so much need, are soon in a sorry plight. However promiscuous these mites may be in their choice of food plants—Melons, Cucumbers, kidney Beans, Hops, Vines, Apple, Pear, Plum, Peach trees, Limes, Roses, Laurustinus, Cactuses, Clover, Ferns, Orchids, and various stove and greenhouse plants being their particular favourites—they are by no means insensible to the difference between dryness and moisture. To the latter they have a most decided objection, and it is only in warm and dry situations that they give much trouble, and it is nearly always in dry seasons that plants, &c., out-of-doors suffer most from these pests. Fruit trees grown against walls are particularly liable to be attacked, since from their position the air round them is generally warm and dry, and the cracks and holes in the walls are favourite places for the red spider to shelter in, so that extra care should be taken to prevent them from being infested; this may best be effected by syringing the trees well night and morning with plain water, directing the water particularly to the undersides of the leaves, so as, if possible, to wash off the spiders and their webs. If the trees be already attacked, adding soft soap and sulphur to the water will destroy them.

SULPHUR is one of the most efficient agents known for killing them; but it will not, however, mix properly with water in its ordinary form, but should be treated according to the following recipe: Boil together in four gallons of water 1 lb. of flowers of sulphur and 2 lbs. of fresh lime, and add $1\frac{1}{2}$ lbs. of soft soap, and, before using, 3 gallons more of water; or mix 4 oz. of sulphate of lime with half that weight of soft soap, and, when well mixed, add 1 gallon of hot water. Use when cool enough to bear your hand in. Any insecticide containing sulphur is useful. The walls should be well washed with some insecticide of this kind. Old walls in which the pointing is bad and the bricks full of nail holes, &c., are very difficult to keep free from red spider. They should be painted over with a strong solution of soot water mixed with clay to form a paint. To a gallon of this paint add 1 lb. of flowers of sulphur and 2 oz. of soft soap. This mixture should be thoroughly rubbed with a brush into every crack and crevice of the walls, and if applied regularly every year would probably prevent the trees from being badly attacked. As the red spider passes the winter under some shelter, frequently choosing stones, rubbish, &c., near the roots of the trees, keeping the ground near the trees clean and well cultivated will tend greatly to diminish their numbers. In vineries one of the best ways

of destroying these creatures is to paint the hot-water pipes with one part of fresh lime and two parts of flowers of sulphur mixed into a paint. If a flue is painted in this way great care should be taken that the sulphur does not burn, or much damage may be done, as the flues may become much hotter than hot-water pipes. During the earlier stages of growth keep the atmosphere moist and impregnated with ammonia by a layer of fresh stable litter, or by painting the hot-water pipes with guano made into a paint; as long as the air in the house is kept moist there is not much danger of a bad attack. As soon as the leaves are off the canes should be dressed with the recipe already given for painting walls, and 2 inches or so of the surface soil removed and replaced with fresh, and all the wood and iron-work of the house well scrubbed. If Carnations are attacked, tying up some flowers of sulphur in a muslin bag and sulphuring the plants liberally, and washing them well in three days time has been recommended.

TOBACCO WATER and tobacco smoke will also kill these pests, but as neither tobacco nor sulphuring the hot-water pipes can always be resorted to with safety in houses, by far the better way is to keep a sharp look-out for this pest, and as soon as a plant is found to be attacked to at once clean it with an insecticide which it is known the plant will bear, and by this means

Fig. 1, red spider (magnified); A 1, ditto (natural size); 2, underside of head; 3, foot; 4, spinneret.

prevent other plants from being infested. These little mites breed with astonishing rapidity, so that great care should be exercised in at once stopping an attack. A lady friend of mine had some Castor-oil plants growing in pots in a window which were badly attacked, and found that some lady-birds soon made short work of the mites and cleared the plants. The red spider lays its eggs among the threads of the web which it weaves over the undersides of the leaves; the eggs are round and white; the young spiders are hatched in about a week, and they very much resemble their parents in general appearance, but they have only three pairs of legs instead of four at first, and they do not acquire the fourth pair until they have changed their skins several times; they are, of course, much smaller in size, but are, however, in proportion just as destructive as the older ones. They obtain the juices of the leaves by eating through the skin with their mandibles, and then thrusting in their probosces or suckers (fig. 2), through which they draw out the juices. These little creature are so transparent, that it is very difficult to make out all the details of their mouths accurately. The females are very fertile, and breed with great rapidity under favourable circumstances all the year round.

THE RED SPIDERS, as I have already stated, are not real spiders, but belong to the family Acarina or mites, a family included in the same class (the Arachnida) as the true spiders, from which they may be easily distinguished by the want of any apparent division between the head and thorax

and body; in the true spiders the head and thorax are united together and form one piece, to which the body is joined by a slender waist. The Arachnida are followed by the Myriapoda (centipedes, &c.), and these by the Insecta or true insects. The red spiders belong to the kind of mites called spinning mites, to distinguish them from those which do not form a web of any kind. It is not quite certain at present whether there is only one or more species of red spider; but this is immaterial to the horticulturist, as their habits and the means for their destruction are the same. The red spider (*Tetranychus telarius*—fig. 1) is very minute, not measuring more than the sixtieth of an inch in length when full grown; their colour is very variable, some individuals being nearly white, others greenish, or various shades of orange, and red. This variation in colour probably depends somewhat on their age or food—the red ones are generally supposed to be the most mature. The head is furnished with a pair of pointed mandibles, between which is a pointed beak or sucker (fig. 2). The legs are eight in number; the two front pairs project forwards and the other two backwards; they are covered with long stiff hairs; the extremities of the feet are provided with long bent hairs, which are each terminated by a knob. The legs and feet appear to be only used in drawing out the threads and weaving the web. The thread is secreted by a nipple or spinneret (fig. 4) situated near the apex of the body on the underside. The upper surface of the body is sparingly covered with long stiff hairs.

G. S. S.

APHIDES AND SULPHUR FUMES.

MR. D. T. FISH has been making some observations on the early appearance of these pests, but if the following remedy is adopted, neither aphides, red spider, nor scale need give much trouble at least on wall trees, which may be cleansed effectually not only of all of them, but every other parasite, and the walls made to look almost as fresh and clean as when new, for all Moss and Lichen shrivel up at once and disappear. This is effected by burning sulphur under the trees in winter while dormant, the fumes of which rush up the face of the wall among the branches and spurs without doing the least harm to the bark, which becomes bright and polished, like that to be seen on trees near a town, where smoke and vapour act in a similar way. Smears of all kinds are not only objectionable in appearance, but consume much time and labour. With a few pounds of sulphur and some old cracked pots or pans, a man or boy may soon go round a garden and do more good in one hour fumigating than could be accomplished in a week by putting smear on with a brush. To make the most of the sulphur, favourable weather must be chosen, which is when the air is still and heavy, and when what draught or motion there may be in the atmosphere is towards the wall to be smoked. Orchards may be fumigated in the same way by putting a pot of fire under each tree, or moving from one to the other instead. This kind of fumigating must be done before the buds have burst their scaly coverings, as I need hardly say burning sulphur is fatal to leaves and young growth. To be healthy, trees must have clean bark, and this the sulphur gives them, or rather it destroys all that seals up their pores, and the parasites thus made to lose their hold are washed off by the rain or carried away by the wind.

J. SHEPPARD.

CONFERVÆ (*C. E. F.*).—The curious substance you found entangled on the Rushes is evidently a mass of some confervoid growth which has become blanched and dried in the sun. The confervæ grow in large patches like so much green hair in ponds and streams. What you found probably grew in some pool, which dried up, leaving the confervæ in a thin layer on the bottom; this dried into the papery tissue you found, which was washed away afterwards and was caught by the tops of the Rushes. It is a very beautiful object under the microscope. There are some points about this substance which I am trying to clear up. I will reply again when I have done so.—G. S. S.

FLOWER GARDEN.

SELF-COLORED DAFFODILS.

No reader of THE GARDEN can have failed to observe the very interesting discussion which has been going on of late respecting the existence of self-coloured Daffodils. Although I make not the slightest pretension to any such authority in the matter of Daffodils as may most rightly be claimed by your various correspondents, I still possess a tolerably extensive acquaintance with them, the result of forty years' observations. The particular current dispute as to the existence of self-coloured Daffodils would most certainly be settled in the affirmative could a floricultural jury, pledged to the truth, the whole truth, and nothing but the truth, see what any other visitor to Mr. Brockbank's garden might have seen two days ago. Without anything being pointed out to me, I was asked to look first at a bed, some 50 yards in length, of garden miscellanea, dotted all over with little clumps of the wild English Pseudo-Narcissus, plenty of which occurs in the meadows near the Mersey. Many shades of yellow, both of perianth and vase, are here to be found, and among the specimens are several in which there is no substantial difference in the colour of the two portions of the flower. These "wild" ones, I understand, have been obtained from various parts of the country.

After this, Mr. Brockbank showed me his large collection of the Tenby Daffodil, *Narcissus obvallaris*, and among these are other examples as plainly unicolour as it is possible for a Daffodil to be. Something, of course, depends upon the conditions or circumstances of the plant; but that is not the question. The question is, do self-coloured exist, not how are they brought into existence, and Mr. Brockbank's garden certainly proves that they do exist. A well-known local florist, Mr. H. Brownhill, who happened to come in while I was there, was asked if he thought he could find a self, and he at once fixed upon the same individuals. In very exposed situations the vase, or, at all events, the upper portion of the vase, of *obvallaris* no doubt does acquire a darker tint than the six pieces of the perianth proper. But this does not alter the fact of unicolourness in individuals placed differently. I have not the slightest desire to befriend any grower in particular simply out of personal regard. I merely state the facts as palpable to the stranger.—LEO GRINDON, *Manchester*.

— Mr. Brockbank asks if all Daffodils are bicolor. My answer is that no Daffodil at present known to me has perianth and cup of precisely the same shade of yellow. If Mr. Brockbank chooses to call *N. maximus*, *N. obvallaris*, *N. spurius*, &c., "self Daffodils" for practical purposes of garden classification I can offer no objection, but when he asks me if two or more shades of colour are the same, as he has practically done several times recently in these pages, I, of course, reply in the negative. Mr. Brockbank sent me a faded flower of *N. obvallaris* as having perianth segments and crown of exactly the same shade of yellow, but I found and proved that it was not so. When Mr. Brockbank is good enough to quote the names of those who, as he says, agree with him, he surely is aware that what anyone may have told him is not legal evidence to me. I ask Mr. Brockbank to prove his flower to be what he says it to be, and this he either cannot or will not do. I do not wish to save a kettle, but I do wish to be convinced of the truth or error of Mr. Brockbank's observations, and he is good enough to remember that I mentioned no conditions, so that he is free to prove this question of colour identity, which is, as I believe, impossible. I insist on proof as on a problem in mathematics. Among hosts of Tenby's in bloom (see p. 331) "we found one clump especially in a quiet corner wherein almost all were selfs." This quotation proves Mr. Brockbank's test plant to be but a shifting index of colouration, it seems, and quite on a par with his artificially grown specimens. I also have partisans on my side, and many of them; indeed, one of them suggested

that the evidence, so far as Mr. Brockbank had yet gone, was more suggestive of hot water than of the kettle.—F. W. B.

NARCISSUS TORTUOSUS.

IN THE GARDEN (March 24, p. 277) Mr. Brockbank says this "appears to be a rare Daffodil" because it is not offered in Barr's, or Ware's, or in Messrs. Backhouse's catalogue for 1882. May it not, let me ask, be offered under some other name, such as *N. cernuus*, or perchance *N. moschatus*? I write with a knowledge of Mr. Brockbank's variety, he having kindly sent me a bloom of it, a withered one, it is true, but simply the *N. moschatus* of the nursery gardens, except that it is smaller than *N. moschatus* generally is (? *N. moschatus minor*). As to its whiteness—"pure greenish white without a shade of difference between crown and perianth divisions"—we all know that yellowish *Chrysanthemums* and other flowers yield blooms of more delicacy and purity of whiteness when grown under glass than out-of-doors. What I especially wish to point out, however, is that any attempt to be quite certain—even tolerably sure, in fact—of any variety of *Narcissus* from Haworth's characters or descriptions is mere guess-work—intelligent and painstaking work it may be, but still only guess-work at the best. In this respect Haworth is far behind even old Parkinson (1629), whose descriptions are often photographic in their accuracy, and whose woodcut figures, Albert Dürer as they may be, show us quite clearly what species he intended to represent and describe. Mr. Brockbank, in alluding to "Hardy Flowers" and to my own "*Narcissus*," forgets that both works were written at a time when comparatively little was known about Daffodils or *Narcissi*, except perhaps the commonest species and varieties. Both books appeared at a time when bedding plants rather than the blossoms of Lady Corisande's gardens were in fashion. Between Mr. Brockbank's own description of his tortuous Daffodil and that of the authority which he quotes (Haworth) there is a discrepancy which I had expected some student of Daffodils would have saved me the trouble of pointing out ere this date.

Mr. Brockbank says:—

N. tortuosus . . . differs from all other Daffodils with which I am acquainted. It holds the same place in the whites which *N. obvallaris* holds in the golden section, coming earliest, and having the same shortened corona and sturdy habit.

Haworth's description:—*N. tortuosus* (the Great Tortuous White Daffodil).

—Divisions of the corolla twisted, sulphur-white, much shorter than the crown, which is cretated and of a citron colour, merging into white.

It will here be seen that Mr. Brockbank says the corona is shortened, while the authority he quotes (Haworth) explicitly states that the perianth segments or divisions are "much shorter than the crown." Now, who is correct? I am very glad to know that, apart from Mr. Peter Barr and myself, the Rev. C. Wolley Dod, Mr. Archer-Hind (to both of whom I am deeply indebted), and other amateurs are now engaged in collecting wild *Narcissi* from all known localities and cultivating them side by side, so that we may some day figure and describe them and so in due time become possessed of material for a thorough monograph of the genus which may include some fitting account of the Leeds, Backhouse, Nelsonian, and other collections of hybrid kinds all of which are now simply awaiting a historian. I quite agree with the Rev. Wolley Dod, who writes to the effect that almost all the older authorities on *Narcissus*, including Haworth, are obsolete, because at the best the characters are ambiguous and unaccompanied by figures, which even quaint old Parkinson knew the value of, seeing that he failed not to supply them in his "Garden of Pleasant Flowers," or "Paradisus Terrestris." I have carefully drawn and described every Daffodil I have seen for the past ten or fifteen years, and have nearly all figures of Daffodils ever published here beside me, yet I know that there must yet be many unseen wild varieties in Europe which well deserve portraiture if only we could secure them for a sitting.

F. W. B.

ST. BRIGID'S CHRISTMAS ROSE.

(HELLEBORUS NIGER ANGUSTIFOLIUS.)

MR. BROCKBANK may rest assured that I did not apply an English name to this plant without due thought; and as to the question of my right to do this, I can well afford to trust to Time as an impartial arbitrator in the matter. At present it is not without interest to note that what Mr. Brockbank calls "our English prejudices" (p. 332) stand in the way of this pretty and suggestive popular name being generally received. So be it. As to the question of its being in no sense an Irish plant, surely Mr. Brockbank knows that. It is not a native of either England or Scotland—in fact not a British plant. That it may not be purchased from Irish nurserymen I admit; that it was not grown at Glasnevin three months ago, may or may not be true; but I might as well say here that, after all the assertions made by Mr. Brockbank, he has afforded us no proof in any way of his plant being our variety. I doubt very much whether Mr. Brockbank has a single example of St. Brigid's variety—that is to say, of *Helleborus niger angustifolius*—in his garden. I know he believes our plant and his own to be the same, but he has afforded no proof that they are so, and possibly he may be mistaken. I can well believe Mr. Brockbank's indebtedness to Miss Hope for information on *Hellebores*, and do not forget that in THE GARDEN (p. 140) he lavished far more praise upon our present plant—that is on what he believes to be identical with our plant—than did either Miss Hope or "Veronica." The true St. Brigid's Christmas Rose needs no praise; indeed, it is quite lovely enough to deserve a yet prettier name if such can be found for it.

At page 332 Mr. Brockbank makes an assertion which is so transparent, that one can easily see further into it than into the proverbial stone wall. "Nobody grows the wild Christmas Rose (*H. niger*), except in botanic gardens." I offer no comment on this statement, but simply ask, is it true? I am, of course, sorry that Mr. Brockbank's "English prejudices" stand in the way, or rather that he imagines that they do so, but, as he wisely observes, "time will show." If it be true that "possession is nine points of the law," then is *H. niger angustifolius* in possession of a definite, pretty, and appropriate popular English name. I have only to add that I more than suspect Mr. Brockbank's plants to be those of *H. niger major*, but if he will send me leaves I shall be able to correct this suggestion in case my inference now made be a wrong one.

Mr. Tymon's remarks on popular nomenclature call for but little remark. His argument is a good one, but his premises are wrong. This is his starting point: "I certainly more than doubt the expediency of any attempt to supersede scientific names by so-called popular ones." No one, so far as I know, wishes to "supersede" scientific names, *i.e.*, Latin ones, by the application of popular ones. It is not a question as to whether Latin or English names are the best, but as to whether both Latin and English names together are not better than either used alone. English plant names must be used wherever English is spoken. To suppress them would suppress all trade in plant products. To prevent confusion, let us have Latin ones also, but that surely is not an argument for their suppression. No; I think expediency points to a great future for English names, but I hope that neither Mr. Tymon nor anyone else thinks that I for one moment think even of such a suicidal course of action as the "superseding" of Latin ones. English names are for the millions who cannot or will not learn either Latin or Greek. F. W. B.

Ornithogalum nutans.—One of the very best spring flowers for cutting, though one rarely sees it so used. It will grow anywhere, sometimes only too freely, increasing rapidly both by bulb and seed. It spreads too freely to be quite a safe plant in a choice flower border, but in some less important place one or two square yards of it will yield a valuable supply of bloom. The flowers, like

some others, greatly improve indoors, for whereas when growing the top of the spike is in bud and the lower part in seed, with a few flowers between, when in water the whole spike becomes flower, and the individual flowers, instead of being half open, rather too green, and inclined to droop, as they generally appear when growing, become wide-open, clear white stars, with a beautiful satin-like lustre. The foliage of this Star of Bethlehem is of no use for cutting. The flowers are beautiful with delicate sprays of Portugal Laurel—not from the strong-wooded terminal boughs, but the broader-leaved twigs of less stiff growth from shady or sheltered parts of the bush.—G. J.

NOTES ON FLORISTS' FLOWERS.

DAHLIAS.—The promoters of the National Dahlia Show are, I see, again determined to hold an exhibition of Dahlias under the auspices of the Crystal Palace Company. Now is the time to see that the plants, from which blooms are expected, are well inured to stand the weather before they are planted out-of-doors. The planting out cannot be done for at least four weeks yet, and those who expect to stand in the front rank should see that their plants are not allowed to become pot-bound, nor checked by exposure to cold or high winds. If now in 3-inch or 4-inch pots and well rooted, they must not be allowed to remain in these until planting-out time; on the contrary, they should be repotted into larger pots, which they will fill with roots in less than a month. The best place for them as soon as any danger of frost is over is a cold frame. They may be placed on a bottom of coal ashes or some similar material, and they must not be overcrowded, else they will not have the stout, short-jointed habit so much desired. On fine days the lights ought to be entirely removed, replacing them at night if there is the least danger to be apprehended from frost. The ground on which the plants are to be planted should be well worked at this season whenever the weather will permit. By frequently forking it over a larger proportion of surface is exposed to the atmosphere than would otherwise be the case, and this is the more necessary if on the ground Dahlias were grown in previous years. If the soil is not considered to be in first-rate condition, it is a good plan to put a few spadefuls of good compost round the roots at planting time.

THE AURICULA.—This is the month in which Auricula fanciers and exhibitors are engaged in watching the development of their choice named varieties and selected seedlings, and also in crossing in order to obtain the best forms from seed. March was exceptionally cold, and everyone must be thankful it is past. Sharp frosts may, however, yet be expected, but we cannot have another month of such weather as that which we have passed through. Early in March Auriculas were very forward for the season, and I was tempted to remove a large number of the most forward plants to a cold frame from the Auricula house. All through the severe frosts of March these plants were kept in the frame; they scarcely made any progress, the frame being out of the reach of sunshine. After being subjected to such an amount of freezing, one would have thought the trusses would have been sadly injured, but they are none the worse. A few otherwise good trusses will, however, be found with badly formed flower buds upon them. These buds ought to be removed with a pair of sharp-pointed scissors, and this will allow the well-formed pips to grow to a larger size, and be of better substance than they otherwise would be. As the plants are growing very freely they will require a larger supply of water at the roots than they did some time ago; indeed, none of them ought to suffer in the least from want of water. A watchful eye must be kept upon them for green fly, which is without doubt the most troublesome insect pest with which we have to deal. It quite spoils the beauty of the foliage if allowed to increase. If it has been destroyed by fumigating in the winter it will not be very troublesome now; but as it is not

safe to fumigate when the plants are in bloom, any fly that may be present must be brushed off with a soft brush. Auriculas do not require very much labour in order to prepare them for exhibition. In the first place, each truss must be supported with a neat stick. A tie must be made round the stem near the foot-stalk of the flowers to prevent it from snapping, which it will do if the flowers are not made secure. When the plants have to be taken a considerable distance to the exhibition it is perhaps best to turn them out of the pots, and to fasten a piece of cloth or paper round the ball of roots to keep it together. They may then be packed closely in a box or basket, and be repotted when they have been taken to the room in which they are to be exhibited. J. DOUGLAS.

KITCHEN GARDEN.

CARROTS AND THEIR CULTURE.

CARROTS when well grown are a profitable crop; but good clean roots upon ground long under cultivation are difficult to obtain. When sowing some sow a few seeds of some of the Brassicas at the same time, or plant a few plants from 5 feet to 6 feet apart after the Carrot seeds are sown. These are allowed to grow during the summer, and it is thought that they serve to keep the Carrots free from insects. Carrots do best on a light, mellow, sandy soil in which they produce clean, straight roots free from canker, but under careful cultivation they may be grown upon most soils if fairly rich. Ground heavily manured for a previous crop should be selected, but not that in which leaf-mould or old vegetable soil has been buried, except well limed, as they harbour wireworm, one of the worst enemies which can attack the Carrot crop. Where obtainable before sowing, give the ground a heavy dressing of wood ashes, mixed with soot, raking it deeply into the surface. Gas-lime spread upon the surface and raked in deeply will also be found a good dressing for ground infested either with wireworm or the Carrot maggot.

CULTIVATION.—The ground having been selected, if intended for the long-rooting varieties, it should be trenched from 2 feet to 2½ feet deep, laying it up in ridges, in which it will get well pulverised by the winter's frosts. During February, if favourable, level down the ridges with a digging fork, breaking the soil into as fine a mould as possible. Fork it over once more before sowing time. For short-growing sorts deep digging will do, breaking the soil up well as the operation proceeds. Early in April rake the surface to as fine a mould as possible, when the wood ashes may be spread on it and raked in. All will now be ready for making the seed beds. The seeds may either be sown broadcast upon beds 4 feet wide, leaving alleys 12 inches wide between them, or in rows 12 inches apart and 1½ inches deep. Sow thinly, and if in beds rake the seeds into the surface; a portion of the soil from the alley may then be thrown upon the bed and raked level. Cut the edges straight and level the soil in the alley, thus finishing the beds. When sown in rows stretch the line and draw drills 1½ inches deep. The seeds may be mixed with sand or dry earth, rubbing the two together, when they will be found more easily distributed. When sown beat them firmly into the drills with the back of an iron rake; cover them over and tread the ground firmly, when it may be raked level, and will require no more attention until the young seedlings appear above ground; they may then be dusted with soot and lime to prevent slugs from eating them, which will often be found the case, especially in damp, clayey soils. As soon as the young plants are large enough, thin them in the rows to 8 inches apart and keep them free from weeds. When the crop has attained its full growth, which will be about the end of October or beginning of November according to the season, lift the roots, choosing a dry day for the purpose, and remove the tops close to the crowns; store them in some dry place from which frost is excluded, or they may be stored in

clamps in the ground, covering them carefully to ward off frost. Several sowings may be made at different times, so as to succeed each other; make the first about the end of February or beginning of March, choosing for the purpose a dry, warm border facing the south. Sow the short growing varieties for this crop. The main crop may be put in early in April, and another sowing may be made about the middle of August to stand the winter and come into use early in spring.

FORCING.—A few early forced Carrots are always acceptable, and may be had at a trifling cost, provided a spare frame can be devoted to them and manure to form a hotbed, or a pit heated by means of hot-water pipes will do equally well. Sow in light sandy soil as near the glass as possible, and for this crop use the Short Horn variety. When the young plants appear they must be kept well watered, and when large enough thinned out to 4 inches apart. Maintain a steady moist temperature from 50° to 55°. The first sowing should be made the last week in January or first in February. Where manure is to be used, make up a bed of good lasting materials, which may consist of warm stable manure and fresh leaves well mixed and turned over several times before the bed is made up. The latter may be 5 feet high at the back and 4 feet at the front, which gives the frame slope sufficient to carry off rain water or any moisture which may collect upon the inside of the glass. After placing the frame upon the bed, put from 12 inches to 15 inches of sandy loam inside, and sow after the temperature declines to 55°, watering occasionally to keep the soil moist. Use fresh linings to keep up the desired temperature. The Short Horn sort will be found to be the most profitable, and having a fine flavour when cooked will be most prized.

VARIETIES.—Carter's Golden Ball is one of the best for frame work. It is nearly round in shape, and comes into use early. French Forcing Horn will also be found to force well and to produce roots of a medium size. For the early outdoor crop, Carter's Scarlet Horn is one of the best, and for general use James' Intermediate. The Long Red Surrey is a good variety for deep soils. Altringham Improved, a green-topped sort, is a heavy cropper and suitable where Carrots are grown largely. WM. CHRISTISON.

LATE PEAS.

SOME advocate sowing early round Peas for late crops, but I could never see any advantage in so doing. I have tried them on several occasions and in various situations by the side of wrinkled Marrows, but have always found the latter the most to be depended upon. I do not say that the latter may be sown as late as the former and with equally good results, seeing that Marrows take about sixteen weeks to come into bearing, while the rounds take only twelve, that is, if sown early in spring, and a little less when sown towards the latter end of spring; but were I asked to name the best late Peas, and only allowed to choose one sort, it would be that grand old Pea, the Ne Plus Ultra. During the last four years I have sown this and three other kinds late, three fresh ones every season, but I have always found Ne Plus Ultra to be the latest and best bearer, and last, but not least, the best flavoured. In short, this Pea would be perfect did it not grow so tall—its only fault. Talk about perpetual bearers! it would take an everlasting bearer to eclipse this kind. During these last four seasons we have made it a rule to sow this variety at three different times, the last being from the 25th to the end of May, and we have always been able to gather Peas from these up to the time when they are destroyed by frost or wind. Last year we commenced gathering from the last sowing the first day or so in September, and continued gathering till the end of October, and still they were as good flavoured as earlier in the season. Two points to be kept in view in growing these tall late Peas is to select a sheltered, but not shady, place for them, and to provide them with good, strong, and long stakes. Some imagine Pea stakes to be

long when they are 6 feet, but those we used last season were 10 feet, and the Peas got to the top of them. We were obliged to gather the pods with a pair of steps, but to this we do not object so long as we got the Peas. Has anyone found any of the dwarf late Peas to eclipse *Ne Plus Ultra*? If so, I should like to know its name. J. C. F.

THE BEST SAVOYS.

Few of the Brassica family are more useful than the Savoy. Its easy culture, taken in conjunction with the weight of produce from a given space, is

to select an open, sunny spot for the seed bed where the soil is rich. After the surface has been raked fine, sow the seed thinly, and then cover it with some finely sifted soil. We cover all our seeds in this way, and the result is a greater percentage of plants than when the seed is raked in in the ordinary way. The after management of the bed will not differ in any way from that of other beds sown with seeds of a similar character, but every encouragement must be given to induce the seed to vegetate quickly. To attain this a moist soil is necessary, and in dry weather nothing is better than to give the surface a good watering as soon as the seed is sown. Then cover the bed with an

Koffee and the Dwarf Elm only require a space of 15 inches every way. The after management consists in keeping the ground well stirred between the plants, so as to keep the surface open and to destroy weeds. J. C. C.

EXHIBITION POTATOES.

THE writer of the article on "Exhibition Potatoes" (p. 286) in his somewhat unfair references to the popular Potato, *International*, has given Mr. Fenn, the raiser of that variety, some cause for complaint. Mr. Fenn had no desire to put that variety into commerce, and it was against his wish

Pritchardia grandis (Veitch).

a matter not to be despised by those who require a large supply of green vegetables for winter use. These remarks apply, perhaps, more particularly to the wants of large families, but for small households the Savoy offers an agreeable change, provided a judicious selection of varieties is made. Where the aim is to get a good-sized well-filled plant, there is nothing to beat the Drumhead. This is a large sort and one which requires a rich deep soil and plenty of room. It must, however, be remembered that it is the first to suffer from severe frost, and the larger the heads the more they get injured. It is therefore necessary to use it as far as is practicable during November and December before severe frosts usually set in. For small gardens King Koffee and the Early Elm are the best, and they do not require so rich soil as the Drumhead. They are also finer in texture and milder in flavour, but unfortunately they are rather more tender than the large growing kinds.

SOWING.—The middle of April is soon enough to sow for all ordinary purposes. The best way is

old mat, which may be either pegged down to the ground or a brick may be laid on each corner to keep the wind from blowing it about. This covering will give shade and keep the seed in a uniform state as regards moisture; consequently in seven or eight days it will begin to grow, and then the mat must be removed, or the young plants will suffer. In showery weather covering the seed bed may be dispensed with, and the plants allowed to grow on in their own way, *i.e.*, except they come up in thick patches, when it is a good plan to thin them out, and if need be the thinnings may be pricked out into another bed; if not, they may be thrown away. To grow Savoy

so as to secure both tenderness and good flavour a RICH DEEP soil is necessary. The most satisfactory way to secure these conditions is to plant on ground that was heavily manured and dug up deeply during winter, and as soon as the plants in the seed bed are large enough they should be planted. The Drumhead should be put out 2 feet apart each way, while small growers such as King

that that was done. It was said, and with truth, that grown on light field soil the quality was far better than under garden culture. That such is the case I have proved scores of times. Bedford Prolific is one of Mr. Fenn's seedlings also, and is one of the best white round garden varieties in cultivation. It is useless to say that exhibition Potatoes are unfit for table use. There are really few sorts now in cultivation—the Flounder, Champion, and Regent perhaps excepted—that may not be classed as exhibition kinds, but these just as much violate Potato canons of taste and form as an over-blown Rose would those of the rosarian. We have, for instance, in the red round Reading Russet one of the best of table Potatoes, and a not less beautiful variety in quality, colour, and form is the spotted Radstock Beauty. Add to these the popular Vicar of Laleham, purple; Adirondack, carmine; Grampian, mottled red; and Beauty of Kent, and a really capital lot of Potatoes is the result.

Of coloured kidneys we get American Purple, the handsomest dark coloured Potato, and the best of all the Americans; Prizetaker, superb in quality and pale red in the skin; Beauty of Hebron, pale pink, a capital kind, and very popular; Queen of the Valley, a wonderful cropper and very handsome, and one which has had a first-class certificate at Chiswick; Defiance, a home-raised kind, having a mottled purple skin; and perhaps the handsomest of all, Mr. Bresee, bright red.

The best white rounds at all points, whether for table or for show, are Sutton's First and Best; Redfont Prolific, Schoolmaster, Fiftyfold, flattish in form; White Emperor, and Premier. Of white kidneys we have Cosmopolitan, Woodstock Kidney, Edgote Seedling, Alderman, Snowflake, and Pride of the Market, an improved Magnum Bonum sent out by Mr. Clarke. This is a list of twenty-four kinds that will give satisfaction, for out of what portions of the crop are not needed for exhibition, and but few tubers are so required after all, there will be ample table food left. I shall not rest until we have eliminated from the best twenty-four show kinds we have all that are held inferior in quality. Raising, selecting, and growing seedling Potatoes is no easy matter, and even the result usually leaves much to be desired.

A. D.

QUESTIONS

Azalea mollis.—How am I to treat plants of this Azalea after flowering?—O. G. [Encourage them to grow, and then harden the growth out of doors, gradually inuring them to the open air.]

Colouring hot-water pipes.—I should be glad to know of an effectual means of doing this. Lampblack and oil is the usual preparation for producing a black, but I want a French grey or white which will not wash off. I presume white-lead paint would not stand the heat.—IXION.

A yellow Rose, equalling in beauty *Mérchal Niel*, but without its rampant habit, is a desideratum to those who require pot Roses for forcing. Can anyone inform me of such a Rose? What experience have growers had with the new yellow Rose, *Etoile de Lyon*?—M. OR N.

Tropical birds.—Can any of your readers do me the favour of referring me to any place where tropical birds are successfully kept loose in a warm conservatory? I have been trying the experiment in a house devoted to such plants as Palms, Tree Ferns, *Seaforthias*, &c., and have had some success. Of course, only such birds can be kept as will not injure the foliage. No appreciable damage has been done to my plants so far; and, on the other hand, the elegant forms and brilliant plumage of such birds as the zebra parrot and the paradise Whydah bird have added a not inconsiderable charm to the house. Having experienced several difficulties (all of which, however, I believe to be quite surmountable), I should be glad to know of others who have been successful.—W. H. P.

Garden walls.—What is the best and most economical material for building a wall for enclosing a garden? It is proposed to build the wall 12 feet or 13 feet high on the one side running east and west for erecting lean-to houses against for early Peaches and Grapes, the other three side walls to be 7 feet high for outdoor Cherries, Pears, Plums, &c. Would walls of the height named be high enough? and which of them would best suit the above-mentioned fruits? Should I include Peaches and Nectarines in the list, none of which would be protected? There is abundance of stone on the estate; the only cost would be digging and working it. Would it be best to build the whole with stone, merely facing the high one for the glass with cement? or how would stone faced on the one side with brick stand the weather? Would the two be liable to part company? or should the high wall be entirely of brick, and the 7-foot ones of stone? All the walls would be 14-inch ones. The best and most economical system is required. A few hints from any correspondent acquainted with such matters would greatly oblige me. I should add that the garden would be on a hill in an exposed situation.—W. C. B.

* * Our readers will greatly oblige by replying, so far as their knowledge and observation permit, to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

SOCIETIES.

INTERNATIONAL HORTICULTURAL EXHIBITION AT GHENT.

APRIL 15 TO 22.

DURING the past week a vast gathering of horticulturists assembled in Ghent to witness the eleventh of the international exhibitions held quinquennially under the auspices of the Société Royale d'Agriculture et de Botanique of Ghent, and on this, as on former occasions, Belgian horticulture, so justly renowned throughout the world, and in which this famous city of nurseries has played so prominent a part, achieved a grand success. So fine an exhibition probably could not have been got together from such a limited area anywhere else in Europe. Though virtually of an international character, the show was chiefly Belgian, and Ghent itself, we imagine, contributed the greater part of it. To those who have seen flower shows in England only there is novelty in such a one as this; one sees a different class of plants, such probably as could not elsewhere be seen, for the Ghent cultivators surpass us in many things, though they are behindhand in others. The great feature of the show was the Azaleas, than which it would be impossible to produce finer. Palms, too, were matchless, and Ferns, Cycads, and other fine foliated plants which we do not seem to appreciate much here were all that could be desired. The display took place, as usual, in the Casino, a large permanent building standing in an ornamentally laid out garden, every part of which was taken up by the exhibits. The main portion of the Casino consists of a capacious hall furnished with galleries, but though so large it had to be supplemented by a temporary structure almost as large, and these two buildings, besides sundry other smaller ones, were filled to overflowing with exhibits. Throughout the arrangement of this enormous gathering of plants, picturesque effect was the main point kept in view, and this was carried out very successfully; both halls were converted into beautiful gardens, no trace of formality being observable. Those who carried the arrangement out deserve commendation. Evidently the Belgians know how to make a beautiful show, very different from that usually seen in this country, always excepting the admirable displays we are accustomed to see at the Regent's Park in summer. No traces of stages were visible; on the contrary, the whole of the exhibits were arranged in tasteful groups. Seen from the gallery, the great hall was beautiful in the extreme. In the central part were isolated groups of fine-foliated plants relieved by large masses of Azaleas, whose brilliant colours enlivened the whole building. Near these were large miscellaneous groups of particular families, such as Cycads, Aroids, Ferns, while here and there huge Palms and Ferns and specimens of other fine-leaved plants reared their stately heads above all the rest, obviating all approaches to flatness or monotony. The walls of the building, too, were hidden as much as possible by groups of tall plants in irregular masses, enlivened here and there by Azaleas and other brilliantly-flowered plants. The temporary hall was extremely bright, containing, as it did, the majority of the flowering plants. Here were placed *Rhododendrons*, hardy Azaleas, Roses, *Cinerarias*, *Spiræas*, and similar plants. As in the other hall, these were placed in irregular beds, and due regard was paid with respect to harmony of colour. Seen in perspective, this hall had a very fine effect, its long vistas of flowers being relieved here and there by stately foliated plants, the whole harmonising admirably. The exhibition was opened on Sunday by the Queen of the Belgians and Royal Family, State officials, and others, and remained open until the 22nd.

It will thus be seen that the exhibition was a most comprehensive one, and every care seemed to have been taken so to frame the schedule as to embrace plants of every class, to give everyone a chance of exhibiting. There were no fewer than 292 classes, though of course some were unrepresented. Provision was not only made in the

schedule for collections and families of plants but prizes were also offered for particular genera. The jury, numbering some 130 members, consisted of eminent botanists and horticulturists from Belgium, England, Holland, Brazil, Switzerland, Italy, and Russia. The judging took place on Saturday, after which the exhibits were arranged so as to give the best picturesque effect.

THE INDIAN AZALEAS formed, perhaps, of all others the main feature of the show, the admiration of everyone, and without them the exhibition would have been shorn of its brightness. Their gay colours alone lit up the sombre hues of the fine-leaved plants, and they were so arranged in every part as to show themselves to advantage. The centre of attraction of the whole show was the two magnificent groups of forty plants each, which competed for the prizes offered to amateurs. The finest collection was that from M. de Ghelincx de Walle, of Ghent. This in every respect was perfection, and probably a better group of Azaleas has never been shown. This, together with the other group from the Comte de Kerchove's garden, was given the place of honour in the centre of the main building, and admirably they were suited to the position. All were huge specimens, grown in big tubs, and everyone was trained Mushroom shape as standards, varying from 3 feet to 5 feet high, a fashion which seems to be characteristic of Azaleas in Ghent, quite unlike our English plan of training in tall pyramids. The faultlessness of the premier group was marvellous, each plant being simply a homogenous mass of colour, which, however, would have been more pleasing had more foliage been visible. The fault in this collection, if fault it be, was that it was too glaring, and probably the effect would have been more pleasing if there had been a few tall Palms or Tree Ferns rising up out of the mass. The varieties shown seemed to be of the ordinary stamp, but we singled out a few as being uncommonly fine; these were *Reine des Pays-Bas*, *Sigismund Rucker*, *Roi de Hollande*, *Apollon*, *Cedo Nulli*, *Duc de Nassau*, *Etdard de Flandres*, *Roi Leopold*, *Jean Vervaene*, *Marie Louise*, *Charles Euke*, *A. Borzig*, *Bernhard Andreas*. Comte de Kerchove's collection was a very fine one, but scarcely so faultless as the other. In both we noticed some large plants of varieties that have been in commerce but a few years, and therefore must have been grafted on large stocks. The other amateur's collection was smaller altogether, and the same remark applies to the collections in the nurserymen's classes, though all were superbly grown, as only Ghent cultivators can grow them. As a proof of the importance attached to Azaleas here, there were no fewer than fifteen classes devoted to them, including those for new kinds. There were classes for forty, thirty, fifteen, twelve, and six plants, so that both large and small growers had a chance to exhibit. The finest collection from nurserymen was that from M. Vuylsteke, which was not much inferior to that shown by the amateurs. It was seen to perfection, as it was placed at the end of the temporary building as a foreground to some noble Palms, Ferns, and other fine-leaved plants, to which the gay colours of the Azaleas formed a beautiful contrast. There were large numbers of new varieties exhibited by M. Van Houtte and others, notes respecting which must, however, be deferred.

GHENT AZALEAS AND AZALEA MOLLIS were also among the most attractive features in the show. The groups of these were arranged in isolated positions in the supplementary hall, and their gay colours had a very telling effect, their delicious perfume pervading the entire house. Being the home of the Ghent Azaleas, one expected to see them represented well, and certainly they were, for a finer group than M. Van Houtte showed for the gold medal it would be difficult to imagine. The plants were about 5 feet high, and formed dense symmetrical bushes completely covered with flowers. The tubs in which they were growing were hidden by a row of *Spiræa japonica*, large specimen plants, as fine as could possibly be. This was a remarkably fine and much admired group. The gold medal group of twenty Azalea

mollis from M. Ch. Vuylsteke was uncommonly fine, and showed this beautiful shrub to perfection. Like the *Azaleas*, *Rhododendrons* were shown admirably, particularly the standard bushes, which were as fine as we are accustomed to see them from the Surrey nurseries, but the varieties were not remarkable, except a few new ones, to which we shall allude on another occasion.

KALMIA LATIFOLIA, in groups of twelve plants in pots, was extremely fine, and never before had we seen it in such perfection in the middle of April, for it is a difficult plant to force into flower early. The first prize collection, from M. Debaets, consisted of plants about 2 feet high and nearly as much across, and literally smothered with clusters of pink wax-like blossoms. The practice of forcing this *Kalmia* is not much in vogue with us, but it deserves to be tried. There were numerous classes provided for, such as *Hydrangeas*, *Deutzias*, *Lilacs*, *Spireas*, and the like, but there was nothing very remarkable about them except the *Deutzias*, which were uncommonly fine, though not superior to what we are accustomed to see at the Regent's Park spring shows. Both of the collections of *Deutzias* shown were grown in Ghent, the plants being about a yard through each way, and masses of white bloom.

ORCHIDS.—Though no fewer than seventeen classes were set apart for orchidaceous plants, the whole collection exhibited was in no way remarkable, either for good culture or richness as regards varieties. It is evident we are in advance of Continental growers as regards Orchid culture. It would not be too much to say that of the numbers exhibited on this occasion there was not what we would call in England one remarkable specimen; neither was there any novelty, except an uncommonly fine variety of *Odontoglossum crispum* from M. Vuylsteke, of Ghent, and another from M. Vervaeet & Co., of Mont St. Amand. The first was remarkable for the large blotches of chestnut-brown on the sepals and petals on a pure white ground. It was one of the finest forms of *O. crispum* we have ever seen. M. Vervaeet's plant was of the *O. luteo-purpureum* section, but very distinct from what is usually seen in that way, the colours being so peculiar.

The grand collection was that in competition for the prize offered by the Queen of the Belgians (a gold medal). For this there was but one collection shown, and that came from Mme. Boddaert Van Cutsem, who is said to have the best private collection of Orchids in Belgium. It contained some 150 plants and about 120 varieties, which, of course, made a rather imposing display. It consisted, among other things, of fair examples of *Cattleya Mendelli*, *Lycaste Skinneri*, several *Cypripediums*, including a remarkable variety of *C. Lawrencianum* with broad and highly coloured dorsal sepals. One or two rather good forms of *Odontoglossum crispum* were shown, particularly one called *roseum*, in which there was a decided suffusion of purple. If about a score of first-rate specimens had been shown instead of this mixed collection, in which were many plants unfit to be brought to an exhibition, the Queen's prize collection would have elicited more admiration.

In the amateurs' class for twenty plants there was but one collection, that from M. Van Geert père. It included *Dendrobium albo-sanguineum*, a kind rarely seen in England in bloom, but a commonly flowered plant in Belgium; *Leptotes bicolor*, a good specimen of the pretty *Phalenopsis Ludemanniana*, *Lælia cinnabarina*, and *Odontoglossum maculatum*. The two gold medals for collections of twenty and fifteen plants were taken by M. Vervaeet & Co., Mont St. Amand, who seem to be alive to the growing demand for Orchids. The collection of twenty plants contained some good specimens of such desirable kinds as *Masdevallia Shuttleworthii*, *igneæ*, *Massangeana*, a fine *Dendrobium macrophyllum giganteum*, *Cypripedium levigatum*, a good example; *Oncidium pubes*, with a fine branching spike; and *Phalenopsis Schilleriana*, with a spike that had carried flowers since December last. In the collection of fifteen from the same firm were

good plants of *Dendrobium thyrsiflorum*, *Odontoglossum cirrhosum*, and a few fine *Masdevallias*.

COOL ORCHIDS were shown in collections of a dozen by two exhibitors, but amongst them there was nothing remarkable. M. Van Geert had the only collection in the class for *Cypripediums*, *Selenipediums*, and *Uropediums*, but none were specially noteworthy. M. Van Houtte showed the only collection of a dozen Orchids, and this was only awarded a second prize. A similar award was made to a collection of six from M. Vervaeet & Co. *Masdevallias*, and even all the cool Orchids, appear to be little understood in Ghent, judging by what we saw there, but no doubt the climate is not so suitable for them as that in England. Among the *Masdevallias* we observed that M. Van Houtte had the new hybrid M. Chelsoni, a good plant, and another called *Parlatorei*, which is similar to it. The class for three rare Orchids was only represented by three *Odontoglossums* from M. Vuylsteke, which included the fine form of *O. crispum* previously alluded to. Only two plants represented the class for new Orchids, and the first prize was assigned to M. Vuylsteke for an *Odontoglossum* called *President Zaldua*, one of the *O. luteo-purpureum* type. The other was a seedling *Cypripedium* akin to *C. insignis*, but quite distinct from it or any other variety we know. *Anæctochilus* and *Physurus* were shown remarkably well both by amateurs and nurserymen, especially the latter. The collection from M. Alexis Dallièr, which won the gold medal, was remarkable both for good culture and variety. It included fine specimens of *Anæctochilus Lowi*, *setaceus cordatus*, *discolor*, and *Dawsonianus*.

NEW PLANTS.—These were, of course, an important feature of the exhibition, and they were shown in large numbers. Ample provision was made for them in the schedule, there being no fewer than eight classes set apart for them, besides the two classes in competition for the silver cups for new plants offered by Mr. W. Bull, of Chelsea. Throughout the whole of the classes for collections there was a decided preponderance of fine-foliaged plants; indeed there was hardly a new flowering plant to be seen. Singularly enough, there was no foreign competition in the new plant classes. The class for six plants newly introduced by the exhibitor was only represented by one collection, that from M. Van Houtte, Ghent, who was awarded a second prize. The best new plant (not flowering) introduced into Europe, but not before exhibited, was *Massangea tigrina*, a Bromeliad with handsomely marked foliage. It was shown by M. Massange de Louvrex, Liege. The second best plant in this class was *Amorphophallus imperialis*, a tall growing Aroid, like the well-known A. Rivieri, but larger. This was shown by M. Van Houtte. The third plant in the class, an unnamed species of *Vriesia* from Brazil, was shown by M. Massange de Louvrex.

The best new flowering plant raised from seed was an *Anthurium* similar to *A. Scherzerianum* shown by M. Vervaeet, and the second in the class was M. de Smet-Duvivier, who showed *Spathiphyllum hybridum*, an Aroid similar to *Anthurium*; the third prize was taken by M. Rossel, with a fine seedling *Imantophyllum*.

Six plants newly introduced in Europe, but not in commerce, were shown only by M. Jacob Makoy & Co., Liege, who showed *Aphelandra Margaritæ*, *Bertolonia Closoni*, *Croton Bennettii*, *Cryptanthus Glasii*, *Philodendron Sodiroi*, and *Tillandsia variegata*.

There were two classes for twenty new plants in commerce, one for amateurs the other for nurserymen. There was but one amateur's collection, and this was from an English gentleman, Mr. James Bray, residing in Ghent. It comprised *Pothos aurea*, *Schismatoglottis Lavalleyi*, *Aralia Regince*, *Amorphophallus Lacourii*, *Aspidium Germinyi*, *Dracæna Lindenii*, *Caraguata cardinalis*, *Alcascia Johnstonii*, *A. Thibautiana*, *Dieffenbachia amena*, *D. memoria Corti*, *Pothos ceratocalis*, *Heliconia aureo-striata*, *Kentia Luciana*, *Bismarckia nobilis*, *Heliconia triumphans*, *Aglaonema Rebellii*, *Aglaomorpha picta*, and *Croton Baron Francis Sellièr*.

From nurserymen there were but two collections, and the first and second prizes were respectively taken by M. Van Houtte and M. Aug. Van Geert, both of Ghent. Among M. Van Houtte's plants were *Aralia Kerchovei*, *A. nobilis*, *Begonia gogonensis*, *Pritchardia grandis*, *Selaginella grandis*, *Cochlostoma Jacobianum albo-lineatum*, *Dracæna Massangeana*, *Wormea Burbridgei*, *Nepenthes Mastersii*, *Leea amabilis*, *Alcascia Van Houttei*, and *Asparagus tenuissimus*. Others comprised *Amorphophallus imperialis*, from the Philippine Islands; *Washingtonia* (*Pritchardia*) *robusta*, a Californian Palm; *Oleobachia macrophylla*, from Central America; an unnamed species of *Anthurium* from the same quarter; a species of *Ataccia* and *Anthurium Smidhtcheni*, from New Granada, all with the exception of one introduced this year.

THE BEST PLANT NOT IN flower was a splendidly-grown specimen of *Gymnogramma schizophylla*, shown by M. Maron, from France, which was by far the finest specimen we have seen of this beautiful new Fern. M. Van Houtte was second with *Cyrtomium falcatum* var. *ternifolium*, a handsome Fern; and the third best plant was *Dracæna Donnetii*, a variety with variegated foliage.

Among hardy plants the best was a very fine seedling variety of *Azalea mollis* called *Bienvenue*, with pinkish salmon-coloured blossoms. This was from M. Vuylsteke. For the second prize M. Froebel and Co., Zurich, had a large-flowered form of *Primula rosea* called *grandiflora*. There was no entry in the class for a new seedling hardy plant not in flower.

For the silver cups offered by Mr. W. Bull there was a somewhat limited competition. The cup for twelve new plants from amateurs, introduced by Mr. Bull, was won by M. Meulenaere, of Ghent, who showed some well grown plants of *Heliconia aureo-variegata*, *Dracæna Lindenii*, *Pavonia Makoyana*, *Anthurium Harrisianum*, *Crinum pedunculatum pacificum*, *Euaenia eminus*, *Licuala grandis*, *Asparagus plumosus nanus*, *Kæmpferia Gilberti*, and *Billbergia paniculigera*. The nurserymen's class for cups of the value of 15 guineas and 10 guineas was represented by M. Van Houtte and M. Van Geert, who were first and second respectively. M. Van Houtte's was a fine collection, including *Licuala grandis*, *Dracæna Lindenii*, *Heliconia aureo-vittata*, *Asparagus plumosus*, *Alsophila Rebecca*, *Davallia fijiensis plumosa*, *Pothos aurea*, *Dracæna venosa*, *Anthurium splendens*, *Anthurium Harrisianum*, *A. macrolobum*, and *Epipremnum mirabile*. M. Van Houtte had *Cyclanthus discolor*, *Heliconia metallica*, *H. aureo-striata*, *Alsophila Rebecca*, *Kæmpferia Gilberti*, *Dieffenbachia triumphans*, *Croton insignis*, *Pritchardia grandis*, *Anthurium splendens*, *A. Harrisianum pulchrum*, *Dracæna Lindenii*, and *Davallia fijiensis plumosa*.

THE *BERTOLONIAS*, *SONERILAS*, and allied genera are great favourites with the Belgian nurserymen, and on this occasion they were shown to perfection by M. Van Houtte, who took both the prizes in the class for ten plants. The plants were in glass cases. Their richly coloured, marbled, and spotted foliage showed up brightly in the subdued light, and they were as much admired as any plants in the exhibition. A selection of the kinds included, of *Bertolonia*, *albo-punctatisima*, *marmorata*, *Hrubyana*, *Legrælei*, *Van Houttei*, *Mirandæi*, and *Ohiendorfi*; of *Sonerila* the finest were *Hendersonii*, *argentea*, *hybrida*, *Wm. Ed. André*, and *Bne. des Marches*. These plants are deserving of more extended culture in this country, but it is only by seeing such a collection that their beauty becomes apparent.

GROUPS OF PLANTS of a miscellaneous character were numerous, and on the whole were admirably arranged, and comprised some wonderfully fine specimens. The finest undoubtedly was that from M. Dallièr, which won the grand prize of 500 francs offered by the Fédération des Sociétés d'Horticulture of Belgium. This fine group numbered some forty plants, and occupied a prominent position in the main building. The most remarkable specimens in it were *Stevensonia grandifolia*, *Anthurium Veitchii*, *A. crystallinum*, *A. Laucha-*

num, *A. Warocqueanum*, *Alocasia atropurpurea*, *Zamia Van Geerti*, *Maranta Kegeljamiana* (4 feet through), and *Masdevallia Shuttleworthii* with eight blossoms. Another remarkable group was that from M. Aug. Van Geert, which took the gold medal valued 200 francs. It also contained forty plants, the majority of which were uncommonly fine, and especially *Microlepia hirta cristata*, 5 feet across; *Zamia Van Geerti*, *Anthurium Gustavi*, a new species not in commerce, one of the finest of all *Anthuriums*; *A. Veitchii*, *Pteris Ouvrardi*, *Dracæna Baptisti*, *Anthurium Dechardi*, and *Pritchardia aurea*. The prize of a gold medal given by the Queen of the Belgians for a group of fifty plants was won by M. Van Houtte with a grand collection, which consisted chiefly of lofty Palms and Tree Ferns, intermingled with standard *Rhododendrons*, including a fine specimen of *R. Veitchii*, *Imantophyllums*, and a few finely grown and flowered New Holland plants, the latter a somewhat uncommon class seemingly at Ghent shows.

FINE-FOLIAGED PLANTS were wonderfully fine; among them were noble Palms, Tree Ferns, and *Araucarias*, which are the pride of the Ghent nurserymen and amateurs. The main building was for the most part taken up by the competing groups in the classes for these, and a very fine effect they produced, for the huge-spreading heads of the Palms and Ferns towered above all the rest and broke the outline in a picturesque way. A specimen of *Cyathea medullaris*, the best Tree Fern in the show, could not have been less than 40 feet high, and many of the other Tree Ferns and Palms were equally remarkable. Cycads, which appear to be grown on a large scale in Belgium, were well represented both from amateurs and nurserymen. Among the former a grand collection from M. Ghellinck de Walle won the gold medal in its class, and an even finer collection of ten plants was shown for the gold medal taken by MM. De Smet Freres. Other collections of Cycads, though not so fine as these two, were creditable. The twenty *Marantas* which took the gold medal from M. Dallière contained some very fine, particularly M. Makoyana, *Wioti*, *Oppenheimiana*, and *Massangeana*, which were better than we had hitherto seen them.

CROTONS were good as regards high coloured foliage and fine varieties, but the specimens were mostly all small and far inferior from a cultural point of view to those we see at London shows. The gold medal collection of a dozen plants came from the celebrated nurseries of MM. Chantrier, at Mortefontaine, near Paris. It contained many grand new sorts of the type of Baron Franck Sellière, which is beginning to find so much favour in England. A scarcely inferior collection came from M. Dallière, but the other lots were inferior, pointing strongly to the fact that Ghent cultivators equal us in Croton culture. *Dracænas* were shown well by one or two exhibitors, notably by M. Pynaert Van Geert, who had a meritorious collection of the best English named varieties.

AROIDS, a class of plants in great favour with Belgians, were well represented from M. Louis Van Houtte's nursery. A collection of twenty-five kinds arranged in one group formed a grand feature, for there was such harmony of form in it such as can only be obtained where plants of one family are associated. The most noteworthy plants in the group were *Anthurium Veitchii*, *Warocqueanum*, both finer than we have ever seen; *Alocasia zebрина* *Thibautiana*, and *Philodendron Melinoni paranense*. M. Van Houtte was also the only exhibitor of a collection of *Dieffenbachias*, but only a second prize was awarded.

BROMELIADS, though not very numerous, were thoroughly representative of this fine family of plants, which find so much favour on the Continent. The first prize collection among amateurs comprised some fine specimens, but, with the exception of *Endrolirion Saundersi* and *E. coralinum*, there were none in flower. The other group from the amateurs' class was a good one, and those from M. Dallière, and M. D. Haene, and M. Van Houtte were likewise fine, but on the whole this family was disappointing, for we fully ex-

pected to find such fine genera as *Billbergia* and *Alchmea* in flower. Gesneraceous plants, too, were poor, only one collection being shown, and this was made up mostly of inferior *Gloxinias* and *Gesneras*.

NEW ZEALAND FLAX (*Phormium tenax*) was quite a distinctive feature of the exhibition; every specimen in the whole collections shown, which could be numbered by the score, were uniformly large and well grown. There seems to be a host of varieties in Belgian gardens of this plant, which differ chiefly in the colour of the foliage, but there is but little difference between a great many of them. A few of the best were the variegated form *atropurpureum*, *macrophyllum*, *Veitchii* and the variegated form of it, and *Colensoi*, also with striped foliage. The prize winning single specimens and pairs were huge tufts of foliage from 5 feet to 6 feet high. All were grown in tubs; the groups of eight plants showed well what a noble plant the *Phormium* is when well grown, as it is in Belgium.

THE PERSIAN CYCLAMEN is a plant that seems to be but little known or understood, judging by the collections of twenty-five plants shown. The first group, from M. de Haene, was a good one, but we doubt if the plants have been grown in Belgium, for they had the appearance of London-grown plants. It was a uniform collection, every plant being large and bearing a sheaf of blossoms, similar to the plants we are accustomed to see at the London spring shows. In contrast with this fine collection were the two others, both of which were below mediocrity both as regards flowers, foliage, and colour.

ROSES IN POTS were, on the whole, poor, there being only one creditable collection; the plants were all small and poorly flowered, and not one could be singled out as a good specimen of a pot Rose. It is evident that we have nothing to learn from our Belgian friends as regards the culture of the Rose and a good many other classes of plants. New Holland plants, for example, are miserably grown, and there was only one group in the class for twenty. This was from M. Van Houtte, and, though small, well flowered; it comprised some uncommon and interesting plants, such, for example, as *Choisya ternata* (which was represented finely), *Pultenaea flava*, *Mitrasia coccinea*, and a few *Acacias*. The Heaths were, like other hard-wooded plants, neither remarkable for size nor high culture; indeed, some of the plants shown in the class for Heaths would not have been admitted to a London show.

AMARYLLISES were an important feature and made a bright show, there being three or four collections of forty plants. Taken on the whole, none of the collection contained any remarkable varieties compared with those we have seen this year in London. There is too much of a sameness in colour among them, and mostly all have small funnel-shaped flowers striped as in the *vittata* type. In masses they are very showy, but individually they are not much. The gold medal collection from M. de Hooghe included about half-a-dozen of what we should term really good sorts, that is with large, finely formed, broad petalled flowers with distinct and brilliant colours. The plants in all the collections were well grown, and those in the first prize group were remarkable for their uniform dwarfness, a desirable point in an *Amaryllis*. There were some half-a-dozen new seedlings shown for the three medals offered.

The classes for *Pelargoniums*, *Auriculas*, *Polyanthuses*, *Primulas*, *Pansies*, and similar plants were miserably represented in the competing classes. The bulk of the plants were poorer than one would see at a cottager's show in England. It is evident that the *Pelargonium* in Belgium is not understood, or it would have been better represented, and as a corroboration of this the fine specimens of cut blooms of zonal *Pelargoniums* that Messrs. Cannell sent from Swanley were about the most admired of anything in the show, and people expressed their surprise on seeing such fine examples. Carnations, too, were very poor, also *Dielytras* and *Heliotropes*. On the other hand, there were one or two extremely good collections of *Cinerarias*: the finest of these, number-

ing some thirty plants, was arranged in a large circular group by itself, and very effective it was. Each of the plants was from 1½ feet to 2 feet through, furnished with large healthy foliage and huge heads of flowers, the quality of which, however, was not equal to that we have lately seen in London; indeed, the whole of the *Cinerarias* shown were not remarkable for high quality of the strain. *Mignonette* is grown in Belgium uncommonly well, and there were three or four fine collections of twenty plants, all large and carrying tall, massive spikes of bloom, and the exhibitors have, moreover, got one of the best strains not inferior to Miles' Spiral and others which are our best sorts here.

ORANGE TREES IN POTS were to us an uncommon feature, but the Orange seems to be a favourite object of culture here, and remarkably well it is grown. There were several collections of pot specimens shown, and in every case the bushes were profusely hung with fruits in all stages of ripening, which, with the buds and white flowers, had a fine effect, arranged in large masses as they were here. Both the large and small-fruited kinds are grown, but most of the collections shown were small fruited, and it seems to be the freest grower and the most prolific fruiter. For conservatory decoration Oranges are valuable, and it is a wonder that cultivators here do not take them in hand and grow them as well as the Belgians do.

HARDY TREES AND SHRUBS.—The most noteworthy among these were the standard Sweet Bays, *Laurustinuses*, and *Clethra arborea*, all of which are probably grown better at Ghent than anywhere. The Bays in particular were remarkable for their perfect symmetrical form and large size. The finest were fully 15 feet high, and scarcely one was under 10 feet, and some fifty specimens were shown in the classes for pairs and fifty. Such a display of pyramid and globular shaped trees was characteristic of a Belgian exhibition, and, though so formal, had an imposing effect in the open air, arranged, as they were, in groups and lines. The *Laurustinuses* in flower, being masses of white, were also a grand feature; likewise the pairs of *Clethra arborea*, which is scarcely less ornamental than the Bays when grown as they are in Ghent. There were several collections of coniferous trees, but they were of the ordinary stamp, and much inferior to what we see at shows here. There were also classes for *Ivies*, *Aucubas*, *Hollies*, and *Yuccas*, but none were remarkable except the variegated *Yuccas*, which were finer than we had ever seen them, the finest pairs ranging from 3 feet to 5 feet high, and simply perfection in every point. The kinds were chiefly *Y. aloifolia variegata* and *Y. quadricolor*. Japanese *Acers* seem to be coming in vogue in the Ghent gardens, for there were several really good collections shown of the *A. polymorphum* type, and groups of them dotted here and there had a pretty effect.

THE VAN HOUTTE PRIZES, consisting of objects of art given by the English Van Houtte Memorial Prize Committee, were competed for on this occasion, and, singularly enough, both prizes were won by the late M. Louis Van Houtte's son. The prizes were for six stove and greenhouse plants and eight *Imantophyllums*. In the first were a few good specimens, particularly small, but neatly trained and admirably flowered plants of *Hedera* *Tulipifera* and *Erica picturata*. The others were *Medinilla magnifica*, small, but well flowered, *Brachysema lanceolatum*, *Anthurium Scherzerianum*, and *Eriostemon floribundum*.

THE IMANTOPHYLLUMS, which are special favourites with Ghent nurserymen, were remarkably fine, particularly the eight with which M. Van Houtte secured the memorial prize. These were all finely flowered specimens, and represented the best varieties, some being new seedling sorts raised by M. Van Houtte. Among the finest were those named M. Todt, Mad. Van Houtte, Mad. Peters, Mad. Donner, the finest flowered sort of all; Louise Kremer, and Charles Van Eckhaute. Besides these, M. Van Houtte showed some dozens of other seedling kinds, which together formed a

brilliant group, unlike anything we are wont to see at London shows.

ENGLISH EXHIBITORS were but few in number, but the exhibits of these few attracted a deal of attention. Mr. B. S. Williams had a magnificent display of Cyclamens, consisting of about 200 large specimens profusely flowered and representing the finest strain yet obtainable. Such an unusual sight was yet grown Cyclamens, that they excited the admiration of everyone, and the Queen of the Belgians at the opening ceremony seemed to be particularly fascinated by them. They were arranged in one large group, and of course were very brilliant, as the colours varied from the purest white to the deepest crimson. For this fine exhibit Mr. Williams was awarded a gold medal of the value of 200 francs.

A gold medal was also awarded to Messrs. J. Veitch & Sons, Chelsea, for a small, but choice group of Rhododendron seedlings of the javanicum type. Among them were some uncommonly fine sorts even superior to those already shown in London.

A group of the double flowered Cineraria Mrs. Thomas Lloyd and some cut trusses of single zonal Pelargoniums exhibited by Messrs. Cannell & Sons, Swanley, won the admiration of everyone, being such an unusual class of plants at a Ghent show. A gold medal was awarded to Mr. Cannell for his group.

The only English exhibitor in the competing classes was Mr. Brown, florist, of Richmond, Surrey, who took a gold medal for three floral epergnes, a silver medal for three ball room bouquets, and a silver medal for wreaths. There was a fair competition, and no doubt Mr. Brown would have secured all the gold medals in the classes he competed in had not an accident happened to his exhibits during the journey which severely damaged them. The other English competitors were Messrs. Foster & Pearson, Beeston, Notts, who took two gold medals for hot houses and a silver medal for frames.

Our notes concerning the horticultural appliances and various other exhibits must be deferred till next week.

NOTES OF THE WEEK.

NEW HYBRID FORMS OF ANTHURIUM SCHERZERIANUM.—Among the most interesting new plants exhibited at the recent great Quinquennial International Horticultural Exhibition held at Ghent from April 15 to April 22 were four most curious and beautiful forms of the above-named brilliant Aroid (whose ordinary English name among unbotanical or florally unlearned persons is the Flamingo plant), all raised by the distinguished French amateur horticulturist, Mons. A. de la Devansaye (at Château du Fresne, near Angers, in Anjou), the president of the Angers Horticultural Society. The names of these four interesting novelties are respectively A. Andegavense, finely figured in a well-executed double plate, No. 2454-5, in 23rd volume of Van Houtte's "Flore des Serres;" A. Devansayanum, figured in the Paris *Revue Horticole* last July; A. Rothschildianum, figured in an earlier number of the same volume of Van Houtte's "Flore des Serres;" and lastly, A. album. The first named of these four varieties was much the strongest of the lot, the seed from which it sprang having been sown by M. Devansaye in 1877, bloomed for the first time in 1880, and first exhibited at Tours in May, 1881, when it was deservedly awarded a gold medal. It holds, I should say, an exactly intermediate position as to depth of ground colour and density and distinctness of maculation between Nos. 2 and 3, as above enumerated, and had some six or eight of its brilliant spathes distinctly spotted with white in various degrees of expansion, showing how fine the other varieties may be expected to become when they attain their full size and development. The second named seemed to me to be the most brilliantly and distinctly marked of the lot, the macules almost resembling small drops of blood on a white ground, and considerably farther apart from one another

than in the other two varieties, while the ground is of a clearer and purer white. It was the offspring of a cross effected between A. magnificum and A. Galeottianum, and the plant shown, being still only in its second year, and bearing only two leaves and one flower, may be expected greatly to improve in size of spathe as it increases in age and strength. The third named was curiously enough obtained by cross-fertilisation almost simultaneously by two other raisers, besides M. de la Devansaye, Mr. Bertrand, and M. Bergmann, Baron Rothschild's gardener at Château de Ferrières, and though a very distinct and curious variety, is, perhaps, inferior in beauty and distinctness of marking to either of the previously named sorts. The fourth named has been, I think, somewhat incorrectly named by its raiser, as it is by no means a pure white, being rather a pale straw colour with the faintest possible shading of red through some parts of the spathe. M. de la Devansaye, however, informs me that he considers it a very valuable plant for use as one of the parents of his future hybridisations, which he is still carrying on with much zeal and activity, having at this moment over 3000 seedlings, the result of divers crossings, among which he hopes to find some fine and distinct new varieties. He has already obtained one exceedingly curious sort with perfectly round spots about the size of a split Pea, of a different shade of red to what the ground colour is, which he considers quite an acquisition. Another of his hybrids named A. dentatum, resulting from a cross between A. leuconerum and A. fissum, is shortly to be figured in the Paris *Revue Horticole*. The raiser also informs me that by sowing his seeds as soon as ripe broadcast over a hot-water tank, and barely covered with soil, he gets them to germinate usually in about eight days, and they generally bloom the middle of the third year after they are sown.—W. E. GUMBLETON.

ST. PETERSBURG HORTICULTURAL EXHIBITION.—An official communication sent to us, from the Science and Art Department, announces that, in consequence of the Czar's coronation, the proposed exhibition and congress at St. Petersburg are postponed until the 5th of May, 1884.

NYMPLÆA ZANZIBARENSIS.—I have just seen flowering specimens of this plant, and as I surmised in my remarks respecting it (p. 335), it proves to be only a form of the common African species N. stellata. It is doubtful even whether it differs at all from the plant known as N. scutifolia. Possibly, however, the plants which I have seen may not be so fine in form as those to which the above name was given, although on comparing them with the description and analytical drawings of Professor Caspary, the author of the name, there appears to be no difference. Plants of N. zanzibarensis are in the Kew collection, so that we shall doubtless soon have an opportunity of seeing whether this kind is worthy of the praise bestowed upon it or not.—B.

CARNIVOROUS PLANTS AT KEW.—In that portion of the T range devoted to the cultivation of so-called carnivorous plants there is a healthy and interesting collection of them. The Sarracenias are in capital health, and from the numbers of strong young pitchers shown on most of them there is promise of a fine display this year. *Droserophyllum lusitanicum* is thriving remarkably well in pans, and we learn that the treatment to which the plants have been subjected for the last two years is diametrically opposite to that usually recommended for this interesting Sundew. Here it is watered as liberally as the Sarracenias. It has been kept very moist all winter, and, moreover, is potted in a mixture of loam and leaf-mould. That this treatment suits it is evident by the fine healthy leaves borne by the Kew specimens and the strong spikes of bloom which most of the plants are pushing forth. *Pinguicula caudata* is represented by a panful of three plants bearing eight flowers, all fully expanded; one plant alone bears four expanded flowers and two stout buds. Grown as at Kew, this *Pinguicula* makes a fine display. *Darlingtonia*, *Drosera*, and other *Pinguiculas* are also well represented in this collection.

Recent plant portrait.—In second number of the *Revue Horticole* for April is a portrait of *ONOSERIS DRAKEANA*, a pretty composite from New Grenada with medium-sized rosy purple flowers borne singly on slight stalks well raised above the foliage, and found by M. E. André on the rocks of Dorotès and the steep banks of the Rio Mayo in a barren region about 3000 feet to 4000 feet above the sea level. In this country it will thrive well in the greenhouse.—W. E. G.

Hardy foliage for hardy flowers.—While believing thoroughly in the principle that a plant's own foliage is the best for associating along with its own blossoms, yet it is sometimes expedient to use leaves of beautiful form or greater variety. I find too often amongst my friends a tendency to use Fern fronds and other hot-house foliage when arranging their vases of outdoor flowers for indoor ornament. Their right to do this is not disputed, but for the sake of those who have no greenhouses even it is pleasant to know that there are many hardy plants which produce beautiful leaves in plenty in the open air of a sheltered garden. One of the best of these is *Heuchera Richardsoni*, which produces silky leaves of a rich, reddish, bronzy colour on slender stalks 5 inches or 6 inches in length. The common Tansy plant and some of the *Achilleas* again yield finely-cut leaves not in any way inferior in feathery beauty to those of exotic Ferns. The purple shoots and bronzy leaves of *Paeonies* or the broad *Saxifrages*, the pinnate foliage of oriental *Poppies*, or the great silvery grey leaves of the *Artichoke* or of *Cardoons* are quite *Acanthus*-like in their nobility of form, and so well fitted for large urns or vases indoors. There are many, many other things, "good things," indeed no poverty at all, in the hardy leaf glory of our outdoor gardens, while some of us think that hardy foliage is best fitted for association with hardy flowers.—F. W. B.

OBITUARY.

MAJOR-GENERAL SCOTT, C.B., F.R.S., late of the Royal Engineers, died on Monday last at his residence, Silverdale, Sydenham, aged sixty-one. He retired from the army in 1871, and became Director of Buildings at South Kensington in the room of the late Captain Fouke. He was elected a member of the Council of the Royal Horticultural Society in 1865 in place of the late Sir Joseph Paxton, and became secretary in 1866, resigning in 1873. He was also secretary to the Royal Commissioners of the 1851 Exhibition.

Seedling Primroses (*P. N. F.*).—A lovely collection, chiefly maroon colour with a conspicuous orange eye, the centres of the petals in some cases being tipped with white. One white, with an orange eye, is also a welcome sort, especially in a cut state.

Dendrobium Falconeri.—We have received from Mr. Hugh J. Scott, Ashfield House, Ballynaveagh, Belfast, lovely blooms of this charming Dendrobe. The plant from which they were gathered (a moderate sized one) was imported last year, and is stated to be now carrying sixty-eight fully expanded flowers, a heavy crop for so young a plant.

Names of plants.—*G. W. P.*—*Fritillaria imperialis*, or Crown Imperial.—*J. W.*—1, *Abutilon vexillarium*; 2, *Cydonia japonica* (flesh coloured variety).—*W. W. B. R.*—We do not recognise the leaf sent. Kindly send a better specimen.—*J. R. S.*—The flower sent has neither anthers nor perfect column, both of which are necessary to enable one to name an unknown plant such as yours appears to be. Kindly send another flower and leaf, and tell us whether it is terrestrial or epiphytal.—*E. L. B.*—*Billardiera scandens*.—*P. W. B.*—*Gagea lutea*.—*W. V.*—1 and 2, double purple and white Violets; 3, *Corydalis bulbosa*; 4, *Narcissus nannus*; 5, *Doronicum caucasicum*; 6, *Dielytra fennosa*.—*S. W. C.*—*Ornithogalum nutans*.—*Nemo*.—*Dendrochium densiflorum*.—*J. H.*—*Tradescantia viridis* and its variegated variety. They often flower in a rather warm, dry greenhouse.—*Anon.*—1, *Leucojum vernum*; 2, *Crocus imperati*.

Erratum.—P. 346, middle column, "Puccinia Buxi." For "on the Olive," read "in moist air."

No. 597. SATURDAY, APRIL 28, 1883. Vol. XXIII.

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SUGGESTIONS FOR THE IMPROVEMENT OF FLORAL DECORATIONS AT FLOWER SHOWS.

As a society's object in offering prizes is to encourage the best use of flowers in decoration, it should point out to intending exhibitors, and especially those in the floral trade, that, whereas a knowledge of flowers and a demand for them is rapidly growing with the public, and that matters of good taste are also now more considered and understood than they have hitherto been, it will be well for them to keep pace with the growth of taste in this direction.

Large numbers of what would be their best customers are lost to the florists because people of good taste know that what they want, and are willing to pay a good price for, viz., a simply arranged decoration, is what they cannot get from the florists. The trade have a mistaken idea that their stiffly wired arrangements of many flowers, having evidently cost much labour, are more willingly paid for, but the better class of customer, who requires a certain thing put on his table in the best form and order at a certain time, would rather pay for the good organisation of what he wants than for laborious wiring, whose only effect is the destruction of the natural grace of the flowers. The trade might also be reminded that trumpet vases and March glasses are entirely out of fashion in the best houses, besides being in any case undesirable forms for dinner-table decoration, and that simple bowl-shaped vases are much better and now more generally used. Exhibitors should be told that the rareness or value of the flowers themselves is a point very slightly considered in awarding prizes. Societies should discourage as much as possible wiring of flowers. Hand-bouquets should be made in a less stiff manner. The use of good hardy flowers and foliage should be encouraged.

As a general rule fewer flowers and those of fewer kinds should be used in one decoration. Classes should be formed for dinner-table decoration consisting of one kind of flower and one kind of foliage, varieties of these kinds being admissible.

Classes also should exist for dinner-table decoration in harmonious colouring, in which the flowers used shall be of one colour and varying shades of that colour, with foliage in harmony, such as scarlet and crimson flowers with red-bronze leaves, pink and rose colour, with warm foliage; yellow and orange, with golden green and golden bronze foliage. The warm colours, viz., scarlet, crimson, pink, orange, and yellow, have the best effect at night. A class is desirable for dinner-table decorations of hardy flowers and foliage only, and a class for hardy flowers and foliage for table in drawing-room. Abolish altogether the class for arch for sideboard which leads exhibitors to worse than wasted effort in the composition of elaborate monstrosities, the like of which are never seen where the slightest taste prevails.

There are so many good materials that look well by day and night, too, that special classes for

flowers that open only at night seem a doubtful class. As a curiosity now and then they might be desirable, or for very special decorations. But for the house generally, flowers that open only at night would be curiosities. All good decoration is to some extent lasting in character, as it ought to be to repay the time and expense and care bestowed upon it. A batch of those lovely Daffodils now in flower cut early in their blossoming, and placed in water, will give a beautiful effect for ten days, and actually improve in size for nearly a week. A good plant of *Aralia Sieboldi* placed in a vase in a hall will adorn the place for half a year, or more if desired. Almost the same might be said of a score of other plants. Who, then, could tolerate in the day the aspect of dishes of things that only open at night, like some Cactuses or Water Lilies? Plants that only open at night have their place, and a very interesting one, but the very short time they last, and the fact that they are so poor in effect in the day, must ever give them a very small place. J.

NOTES.

LAPAGERIAS.—I wonder no one has noticed the remarkable resemblance of these plants to the *Amaryllis* tribe—*Alstroemerias*, for instance. If one reads a description of *Lapagerias* in any botanical book it is especially mentioned that the flowers are like *Bomareas*. Everything seems, to my mind, to favour the idea that they are pretty closely allied to the *Amaryllidaceae*. Look at the root, so like a *Bomarea*, only perhaps rather more fleshy; look at the leaf, so like a *Bomarea* leaf; look at the shape of the flower—even to its markings; at the colour; at the country it comes from, which is the home of *Bomareas*. The *Lapageria* is a sort of semi-woody *Bomarea*, which becomes wholly woody in its form of *Philesia* or *Philageria*. The *Lapageria* keeps the habit of throwing up its strongest growth from underground, and yet can make fresh growths from its old wood. This idea is not my own, as it was suggested to me by the late foreman at Messrs. Osborn's, at Fulham, but now *Bomareas* are becoming more common I dedicate the idea to Messrs. Carder & Shuttleworth, who will doubtless soon present us with hybrids of *Bomareas* and *Lapagerias* instead of hybrids between *Lapageria* and *Philesia*.

OF SINGLE FLOWERS some ten years or more ago I wrote to Mr. Keynes, of Salisbury, asking whether he could supply me with single seedling Dahlias raised among the double seedlings, suggesting at the same time there would certainly be a large sale for all single flowers, and that single Dahlias might be (I had never seen one) specially beautiful. I forget the answer, which was "no" in one form or another, but I imagine that a good deal of money might have been made if Mr. Keynes had foreseen the future. Even now we have not half enough of those splendid particular Dahlias, half white and half maroon, of which every raiser of doubles must throw away many single seedlings. It is the same with Hollyhocks. These are to my mind far too double; semi-double red, or cerise, or mauve varieties would probably be far more beautiful than those full double ones which look like coloured penwipers. Some eight or ten years ago I asked Mr. Chater, of Cambridge, to save me single seedlings, but again met with a refusal; I think he said he never raised any single seedling Hollyhocks. I can assure growers of hardy plants

that the single mauve and cream-coloured *Althæas* (Hollyhocks) are splendidly beautiful, and ought to be asked for of all nurserymen professing to sell double Hollyhocks, as in this way alone do they ever get to understand what the public really want. They are not before the times, but far, far behind. I see Mr. Thompson is offering the single red *Opium Poppy* (called by him var. *Danebrog*) with a white blotch. I have got out at railway stations, stopped cabs, and committed every enormity for years to get seed of this beautiful plant, which ought to have been common long ago—as common as it is in France, only these horrid double things have thrust it out of our English gardens. How long will it be before someone offers seed of the lovely pale lemon *Sunflower* one sees in France, which is almost the colour of *Oenothera Lamarckiana*? And when will French Rose growers send us seedling single or semi-single Tea or other Roses? I fancy a *Niphetos* or *Maréchal Niel* with about ten or twelve petals, or *La France*, for instance, would be something unbelievably lovely. Mr. George Paul is offering a fine crimson single seedling, but the great Rose growers ought to have quantities of good varieties, and have done this long ago. I have for a long time been trying to get good seedling single Roses, and Mr. Laxton, of Bedford, has been kind enough to assist me. I believe *Rosa Brunonis*, which is almost unknown in nurserymen's catalogues, is about as valuable commercially, and would have as large a circle of admirers, as the finest double varieties; if it were some new kind of *Cistus*, or *Corchorus*, or *Eucryphia*, it would find a sale at 10s. a plant. I am not at all for having no double Roses or other plants, but we are beginning to see the beauty of single flowers of fine decorative form, and we find at the same time the great difficulty of buying what we want. Where, I should like to know, can one obtain a collection of single Tree *Pæonies*, such as we see on Japanese fans and screens, some of which must be among the most glorious flowers of the earth? or where can one obtain in Europe the single red Cherry, which seems to be as common in Japan as our white wild Cherry? The double I can get for money, but not the single. Flowers remarkable for colour, but not for form, are probably improved by doubling, but who wants a double Lily?

Bingham, Notts.

FRANK MILES.

Music at the Horticultural.—We would venture to recommend the managers of the Society to add half-a-dozen Scotch bagpipes to the musical resources of the conservatory and to have them tuned on the premises, for the Society, by placing a loud band in the midst of the flowers, show little confidence in their power to charm. Any conversation in the consequent din is an unpleasant effort; the building being very unsuitable for music, the sound, as a lady remarked to us, is a "braying" one, which by no means goes well with the many pretty plants and their associations, and any talk to friends or owners they suggest. It would be easy to accommodate the band somewhere else. The people the Society desire to attract have good music in their own homes; and were it not so, London is already so well supplied with music in public places, that we might be spared it here, except on the lawn or in some adjacent building. It is not only the sound which is objectionable, but the mass of people who sit round the band impede movement along the flower stands to a very inconvenient degree.

AMERICAN NOTES.

Will posts set top end down outlast those set top end up?—It is believed by many that posts set in the ground in a position the reverse of which they stood while growing in the tree will last longer than when set top end up. In the spring of 1879 I selected seasoned sticks, 3 feet long. These were split in two, and then cut in two crosswise, making four pieces of each. One set was placed in well drained sand, the other in clay soil. In every case two pieces were set side by side, with earth between, one as it stood in the tree, the other reversed. I tried thirteen kinds of timber. Some of these were young wood with the bark on. All contained some heart wood. Those set in sand were examined in the autumn of 1881. In the case of the Beech, Sugar Maple, Ironwood, black Ash, and black Cherry, the piece reversed or placed top end down was somewhat most decayed. In the case of red Maple, American Elm, Butternut, and red Elm, the piece set bottom end down was a trifle the most decayed. In the case of Basswood, white Ash, white Oak, and blue Ash, there was no perceptible difference. In the autumn of 1882 the posts set in clay soil were examined. In the case of the red Maple, Sugar Maple, American Elm, Basswood, Butternut, red Elm, the piece set top end down was most decayed. In the case of Beech, white Ash, black Ash, black Cherry, the piece set bottom end down was most decayed. In the case of Ironwood, white Oak, blue Ash, there was no perceptible difference. I infer that where one piece decayed more than the other it was caused by some trifling difference in the sticks. The freshly sawed ends in each case were placed uppermost, and came an inch or two above the ground. In some cases one half of a stick (one piece certainly the reverse of the other) lasted considerably better than its other half. As will be seen, it was sometimes the top end down which lasted best, sometimes the bottom end down, and in some cases there was no palrable difference in durability.—W. J. BEAL, in *Scientific American*.

Protection and growth of forests.

The American Association for the Advancement of Science, in its memorial to the several State governors on preserving and increasing the forestry supplies, makes, in substance, the following recommendations: 1. To protect by law trees planted along the highways, and to reduce taxes for encouraging such planting. 2. To exempt for a time from tax the increased value of land from planting trees in bare regions. 3. To appropriate money to existing societies, to be applied as premiums for successful tree planting. 4. To offer prizes for the best reports and essays on practical forest raising, to be published and disseminated. 5. To encourage educational institutions in introducing a course of instruction on tree raising—such as by correctly labelled specimen plantations and the distribution of seeds. 6. To impose penalties for careless or wilful setting forests on fire, the waste from which cause has in some years greatly exceeded the amount of timber used.

Californian Lilies.—One of the bulbs one meets with the greatest difficulty in growing, says Dr. Kellogg, is the Lady Washington Lily. The last time I was out I took a thermometer to find the temperature where it thrived best in a wild state, also to consult the conditions under which it grew. There is one fact connected with the subject that if followed up might throw great light upon the culture of Californian bulbs. It is one which I have intended to investigate myself, and the only reason why is the distance and mountain-climbing necessary to investigate the subject. It was a case of the Washington Lily growing in the basin of a rock. The remarkable feature of this was: the bulb was as large as the top of one's head, and lying upon the ground were stalks 12 feet in length, carrying from fifty to a hundred flowers. Now, if anyone could investigate the condition under which this growth was made, it seems to me that it would throw great light on the subject. This Lily will not grow in

sand, nor a great many other bulbs in California. I have seen a great variety of bulbs grow in these rocks where, in rainy seasons they got a great deal of moisture. Liliun Humboldtii will grow in California. These seem to require the morning sun. Down below Santa Barbara one may go up a ravine, and if the ravine runs east and west, the Lily will always be on the northern slope, and perhaps on the other side not one will be found. Where the sun strikes when past the meridian you will not find a solitary one growing—that is where is no timber; but if the ravine is shaded, trees growing over it, protecting it from the afternoon sun, it will grow on the one side as well as on the other. As regards soil, a strong loam for Humboldtii would be better than leaf mould.—*Pacific Rural Press*.

Apples for export.—An interesting account of the method of selling Apples in England was given recently before the Massachusetts Horticultural Society by Mr. Charles F. Curtis. He stated that this is done wholly by auction. There are five auctioneers in the business in Liverpool, and all the Apples received are sold by one of them. The sale is held in a large amphitheatre, in the centre of which is a large table, on which a barrel of each mark is poured out as a sample. Each auctioneer sells for three-quarters of an hour at a time, and the sales continue, if necessary, till ten o'clock at night. Apples are sold in lots of twenty barrels each. The understanding is that the Apples shall be perfectly tight in the barrel, when such bring 25s. per barrel; "shakers," or those not tightly packed, will bring 4s. less. The next grade is "wet and wasted," which bring only half the price of the best. The Baldwin is the only variety sold to any amount; it is the only one which can be obtained in sufficient quantity to sell by the thousand barrels. Retail lots and odds and ends are not wanted. Sales are held three days in a week. The trade dates from about ten years ago. When it became apparent that New England could raise Apples enough for its own consumption, the New York growers began to ship. In packing, a basket of high-coloured and medium-sized specimens are placed in the bottom of the barrel as close as possible, with the stems all down, and the barrel is shaken as often as a basketful is put in. It is filled half an inch above the chimes, the head is pressed in by means of a screw, and the barrel is then turned over and marked on the faced head, so that when opened it shows an even and uniform surface. Apples thus faced will bring from twenty-five to fifty cents more than those not faced. There is very little demand for sweet Apples. Apples are sometimes shipped successfully in warm weather, when later shipments in cooler weather will decay. Mr. Curtis, in answer to an inquiry, said he did not think that cold storage would keep Apples a month later than ordinary, and a great disadvantage is that they must be used as soon as taken out. Now very few Russets are stored, owing to the improvement in early Southern Apples, which formerly were shaken off and raked up, but now are gathered and packed properly.—*American Garden*.

Fallacies about lawn mowers.—There are no lawn mowers in existence that will satisfactorily cut Grass 5 inches long—that is, 5 inches above the level of the knife-plate—nor are there any 14-inch lawn mowers in existence, or 12-inch ones either, that a boy of twelve years can easily use. It is hard work for a man to use either, and slavery for a boy of sixteen years. The weights which either a man or a horse can drag or push one day with another without hurt have often been estimated. I cannot say what they are at this minute, but I know a 12-inch or 14-inch lawn mower represents about the maximum for a man. As to the reputed "long-grass" cutting mowers, the inventor and the maker of one of these machines, which I shall call the "Incomprehensible," called here one day with an eye to improvements on mowers, and the inventor said his "Incomprehensible" would easily cut Grass 6 inches long, and had cut it. I asked him to point out an example of the long Grass it would cut anywhere in

the pleasure grounds, which he did. He was willing to stake either half a dozen or a dozen bottles of champagne that he could make his mower cut it, and I at once closed with him, promising, as the factory was not far off, to send for one of his new machines for the special purpose, he in turn promising to come and push it. I fulfilled my share of the bargain the next day; but when the day appointed for the inventor's promised visit came, I received a letter from the manufacturer saying, "Our Mr. So-and-so had been suddenly called away, and could not come." I wrote in reply that I was open to carry out the bargain at any other time, but although the inventor has often been in our neighbourhood, he has given me a "wide berth" ever since. He will know who writes this when he reads it; and I take this opportunity of stating that I still expect him either to fulfil his promise or send the champagne.—AN OLD LAWN MOWER.

ORCHIDS.

PEAT FOR ORCHIDS.

ONE is surprised to read of peat for Orchid purposes becoming so scarce in England, that we are likely to be reduced to the use of Cocoa-nut husks as a substitute. I doubt if one gardener in fifty uses Kent peat for any purpose or finds a need for it, as it is expensive to buy all one wants of that material, though I admit it is good, and it is well that it is so, I have invested in Kent peat of two sorts to the extent of a few small bags in the course of many years, just by way of experiment, but I do not intend to have any more of it, as I find that the peat on the estate here is almost of the same character, and of which possibly we have a thousand acres. It consists principally of the roots of the common Bracken which has been growing on the Chase since and probably before the time of Robin Hood. These roots tear up in mats of fibre, and all over the "Dukeries" the same material grows even more extensively than it does with us. I have also seen it in many parts of England. In some parts of Yorkshire there is a kind of peat which, though black and a real peat, does not produce Heath, but mountain Grasses, and this is what we use a good deal of for many purposes. Before using this for Orchids the large sods are thoroughly well beaten till all the small earthy particles are shaken out, after which the sod is just of the texture of a door mat, the roots of the Grasses being like pin-wire almost, and in the mass so elastic that ram it as one may it never becomes sodden or sour. This fibre put in a crate, or on a block, makes an excellent bed for Orchid roots. Enquiry would, I have no doubt, reveal an endless supply of it, for I have seen much of it in some parts of England and Scotland, and I have seen as finely grown Orchids in such a compost as I have seen in any other. I apprehend that it is the texture of the material for Orchid potting which is the point of most importance, and in that case probably almost any kind of turf shaken free of its earthy particles would suit, even loamy turf of good fibre; but peat turf, such as I describe, lasts by far the longest. Sods of it which we have had laid up in an open shed for twelve months are so tough at the present time that it requires a man's strength to pull a good sod asunder, and a section of one cut by the knife reveals a mat-like texture 1 inch or 2 inches in thickness. This with green Sphagnum and charcoal—all home gathered or made—supplies us with all we need for Orchids.

J. S. W.

Orchids at Sudbury House, Hammer-smith.—There are now in flower here Cymbidium Devonianum, quite a host of Cattleya citrina, and a very fine Odontoglossum Rozzli, the lip of which is 2 inches in width, and the purple colour very deep indeed, extending nearly half up the petals. On the Dendrobiums there are literally thousands of flowers, the most conspicuous being D. chrysotoxum, densiflorum, Devonianum, and thrysi-florum. On Odontoglossum Alexandræ there are some dozens of spikes and some good flowers, as

well as on *O. triumphans*, *mulus*, and *Ruckerianum*, *O. Donnianum*, in the way of *O. muculatum*, is a charming Orchid, and very dark. The *Trichopilia* are likewise in grand condition, the whole being in flower, and some of the bulbs producing two spikes, one of each of which there are four flowers. *Vanda* *suavis* and *cærulescens* are also finely in bloom.—W. V.

Dendrobium Devonianum.—I have a plant of this Dendrobe in flower which has nine spikes 3 feet long covered for 2 feet down to the tips with flowers, some of the spikes bearing sixty; the whole number of flowers is 343. It is a sight worth seeing, seeming to make the whole house swim in a sort of lilac coloured haze.—E. H., *Aig-burth*.

Orchids at Clovenfords.—I recently saw some fine Vandas in flower at Clovenfords; upwards of twenty were out at one time, some with three spikes, and a great many with two on each plant. Of snavis there were five different varieties, all alike beautiful, and a great many examples of tricolor. The variety called Dr. Paterson's was very fine, nearly as good as the Dalkeith variety. Amongst other Orchids I noticed a grand specimen of *Cattleya labiata* Gaskelliana bearing fine, very large flowers; *C. Trianae* alba had been fine, but was just over. *Lælia superbiens* had twenty-three bulbs and seven young growths—a fine plant of this noble *Lælia*; *Cattleya intermedia*, with a forest of bulbs and ten flower-spikes, was magnificent; in fact, the general condition of the Orchids at Clovenfords is in every way excellent.—ROBERT GROSSART, *Oswald Road, Edinburgh*.

Orchids from Bridge of Allan.—Dr. Paterson sends us from his choice Orchid collection at Fernfield the following remarkable specimens, viz., *Odontoglossum Halli leucoglossum*, a fine spike, 2½ feet long, carrying ten flowers, each about 4½ inches in diameter. The large pure white labellum of this variety renders it extremely handsome; a flower-spike of the typical form sent along with it strikingly exhibited the superiority of the white-lipped variety. Dr. Paterson adds, "Don't you think the flowers mimic a band of Christy Minstrels just about to dance?" The comparison is an apt one. Another remarkable specimen is a spike of the curious and weird-looking *Uropedium Lindeni*, which Dr. Paterson likens to an octopus. The three long sepaline tails measure fully 18 inches long, and are of a purplish colour. It is very nearly allied to *Cypripedium*, but the segment that should have formed the pouch has lengthened itself into a tail like the other two. The spike sent bore four such flowers, and was cut from a plant bearing three spikes, a proof that the plant's requirements are understood at Fernfield. Dr. Paterson also sends a flower of the rare *Trichopilia lepidia*. The flower is similar to that of *T. suavis* in form, but larger, and the sepals and petals are of a dull vinous purple, while the colour of the labellum is a rich shade of crimson.

SHORT NOTES.—ORCHIDS.

Dendrobium Wardianum.—Mr. A. Wright brought us from Chiswick the other day a very fine bloom of one of the very best varieties of this Dendrobe. It measured 4½ inches in diameter, and its colours were unusually bright and beautiful.

Curle's variety of Cattleya Mendelli.—When at Melrose the other day I was much struck with this fine *Cattleya*. Its sepals and petals are white, and the lip measured 2 inches in diameter without being flattened out of its natural shape. It is well fringed, and its beautiful purplish tip is over an inch in depth.—ROBERT GROSSART.

Orchids in Perthshire.—Mr. Macdonald, Woodlands House, Perth, sends us flowers of *Trichopilia crispa* marginata, rather a handsome variety, and of *Cattleya Mossie*, the latter certainly beyond the average both as regards size and beauty; and on a spike of *Odontoglossum Pescatorei* the flowers measure 3½ inches across, and the bulbs 6½ inches in circumference and 4½ inches in length—the latter a good chocolate colour and quite glossy. Such Orchid blooms as these are by no means common.

EARTHING SEEDLING PLANTS.

THIS is a useful operation in connection with the raising of seedling plants at all times, but never more so than in spring and early summer, when in most gardens seedling plants are raised more or less in large numbers. It consists in shaking over the young plants some fine earth when the leaves are dry. The nature of the material used must be selected according to the requirements of the subjects to be dealt with. In the case of choice flower seeds raised under glass, a finer material will be necessary than for those raised out of doors. For such purposes I select a mixture of leaf-soil and good, mellow loam in equal parts. This I run through a fine-meshed sieve, and add to it about one-quarter of silver sand. I use this mixture for earthing such tender plants as *Petunias*, *Verbenas*, *Asters*, *Stocks*, and many other similar plants, and I find it to strengthen them wonderfully. I dust each lot of plants over about three times before they are removed from the seed pan. The first application is given as soon as the second pair of leaves have been made, and, at intervals of a week, another dusting is given. The character of the plant's growth must decide how much must be given at each operation. For instance, the *Lobelia* grows naturally so close to the soil that earthing is unnecessary, but such subjects as *Asters*, *Stocks*, *Verbenas*, and *Petunias* grow with a longer stem, and these are the plants and others of similar growth that are most benefited by being earthed while young and tender; in fact, the young plants are strengthened by the practice beyond belief, as will be quickly proved by experience and observation. It is not difficult to understand in what way it benefits the plants, because if the material is laid on sufficiently thick it will encourage the formation of surface roots. New roots mean additional strength in the plants, and what is more the stems of the young seedlings receive support from the application, and are thereby benefited by it in several ways; this remark applies to all subjects to which this earthing process is applied. In the case of kitchen garden crops I use any of the old material from the potting bench, first running it through a sieve. This compost I use freely over most beds of seedling plants, especially such as Cauliflowers, Broccoli, Brussels Sprouts, and indeed any of the Brassica family. In dry weather, when the plants want water, it is given them in the evening, and as soon as the leaves get dry next morning this mixture is shaken over them to the depth of a quarter of an inch; this keeps the soil about the roots longer moist than it would be without such a covering, and if this practice is continued once a week for three or four weeks the plants will make rapid progress. One barrow-load of soil at each earthing will suffice for all the seed beds in a medium-sized garden. J. C. C.

THOMAS WILLIAMS, OF ORMSKIRK.

ON looking over some bound volumes of THE GARDEN I am reminded often of one who was taken from us in the last days of 1881, and who was so frequent a contributor that many will be interested in knowing a little more about him. Thomas Williams was no common man. As a gardener he was remarkable, but even I, who knew him intimately, had no idea that he was a poet. About a fortnight since a handsomely bound volume reached me by post, without any accompanying letter of explanation, and on opening it I found on the title page, "Poems by the late Thomas Williams, of Bath Lodge, Ormskirk." The preface states that the work is published in consequence of a wish expressed before his death.

I well remember the first visit I paid to Bath Lodge. My family were staying at Southport, and I dropped a note to Mr. Williams to ask if I might visit his garden. A cordial invitation came by return of post, and on a fine autumn morning I went over and found him in his shirt sleeves at work in his garden. It was a quaint spot, the house being of a builder's Gothic in style, and whitewashed. There was a thick wood on one side, and a stream of beautiful water, which came

from a copious spring in a farmyard near at hand (and from which the place derived its name of Bath Lodge), ran through the grounds. The garden was all laid out in narrow beds, and these were crowded with hardy plants in great variety, for there must have been more than a thousand sorts in this collection. Mr. Williams knew more of plants than any man I ever met, his knowledge being not only that of the practical gardener, but of the botanist also, and his acquaintance with hardy plants was wide and thorough. I spent a long day with him, joined in his simple dinner, spent a most pleasant time, and came away very much wiser than I went. He afterwards visited Brockhurst during the time of one of our great flower shows, and my children well remember his visit, and the marvellous velvet waistcoat he wore on that occasion. He was otherwise clad in gray, but his waistcoat was like the showiest parterre in his own garden. He made himself most agreeable to the circle here, his conversation being interesting and incessant, but nobody thought they were in the presence of a poet. His manner was quiet and most unassuming. He was a teetotaler also, I believe, and when I was at Bath Lodge I was amused at his beverage, which was cold coffee. He said he found he could work best on that of anything.

Here is one of his poems which describes Bath Lodge, and furnishes a fair sample of his muse:—

THE BENCH BY THE WALL.

My cottage it stands at the end of the lane,
And though very humble, I never complain;
If the sun shines at all, it is sure to shine there,
And I'm always content whether rainy or fair.
From those who may hate me I've nothing to fear;
Wherever they may be they never come here;
And my friends I make welcome whenever they call,
And we chat and we laugh on the bench by the wall.

When the buds in the spring-time are ready to burst,
In my old-fashioned garden they open out first;
And the flowers that the rich man knows nothing about
Ere the winter has left us are all peeping out.
At all times and seasons some sweet things are found,
And blossoms to smile upon all the year round;
And some like green carpets star-paughed do crawl
Round the steps of the door and the bench by the wall.

I would not change my dwelling for palace or hall,
For my cot is my castle, although very small;
All the windows look out on a garden so gay,
And are wreathed round with Roses that seldom decay.
When I chance in the summer to open them wide,
The Jasmynes and Roses come dangling inside
With beautiful freedom; but still after all
I would rather sit out on the bench by the wall.

It will be seen that the poetry is not of the highest character, but that it savours of the homely. Many of the pieces are of a religious character, and several are descriptive, especially those about Ludlow, where Mr. Williams was born. These were written for a local guide book. He was a self-educated man. In his youth he worked in a woollen factory, but when seventeen years of age he was taken to be under gardener by the late Mr. Price, of Plas Cadnant, in Anglesey. Thence he went to Liverpool, and at last he became head gardener to Lord Balcarres, at Haigh, near Wigan. Lastly, he entered the service of Edward Stanley, Esq., as farm bailiff, having the management of his estates near Ormskirk. He was a worthy man in every way, and it is pleasant to have this last fruit of his busy life. WM. BROCKBANK.

QUESTIONS.

When to cut Stephanotis blooms.—Will some correspondent kindly inform me whether the flowers of *Stephanotis* keep better after cutting if instead of cutting them immediately they are open they are left to be cut the next day?—S. S.

Vine tendrils.—Can some Grape grower tell me why Vines run to tendrils in many instances instead of bunches. The Vines are twenty-eight years old, and, I believe, have hitherto borne heavy crops. In house No. 1 the roots were lifted and a new border made twelve months ago last autumn; house No. 2, which was treated in the same way, bore a good crop last year, finished it well, and promises to do the same this year; but No. 1 and No. 3 (the roots in the latter not lifted) were in much the same state last year when I took charge of them, viz., producing tendrils instead of bunches. The Vines have a fair amount of roots, but they lie deep in the border; they are planted inside, and the roots run outside.—VITIS.

PLANTS IN FLOWER.

FLOWERS FROM A LONDON GARDEN.—Colonel Stuart Wortley sends us some specimens of Tulips, Anemones, and Narcissi, which he grows in London fairly well. There is no difficulty whatever in growing flowers in London, only people pick the best possible way to prevent success by surrounding themselves with walls, hedges, hen houses, and other obstructions, which prevent the sun from warming the earth and cheering the plants.

FINE VARIETY OF CATTLEYA AMETHYSTO-GLOSSA.—Of this lovely Orchid, Mr. Peacock's gardener sends us from Sudbury House, Hammer-smith, the finest variety that has yet come under our notice. The flowers (three in a cluster) are not remarkable for size, but the colour, particularly the spots on the sepals and petals, and the purple of the lower lobe of the labellum, is intensely rich. None of the forms of this *Cattleya* are poor, but seldom have we seen such a fine variety of it as this is.

WOOD ANEMONES.—We have received from Mr. Webster, Llandegai, Bangor, some lovely Wood Anemones, purple, red, white, and blue, which grown well in a garden would be charming. Mr. Webster finds that there are at least four distinct forms of these Anemones, viz., blue, pink, unspotted white, and one with the exterior pink and the interior white, colours quite constant and distinct on the Anemones at Penrhyn. The blue form, he says, is lovely this season, and the pink amongst the masses of white where it grows is very conspicuous.

ROSES.—From Colonel Hagart's conservatory at Eastbury Manor, near Guildford, we have received magnificent blooms of Reine Marie Henriette and Gloire de Dijon Roses. The plants from which they were cut are about four years old, and are on their own roots; at present they are said to be bearing hundreds of buds, and full blooms have been gathered from them since the 1st of March amounting to about 250 of the red kind, and over 300 of the Gloire de Dijon, and even now Mr. Fullegar, the gardener, tells us that he could cut fifty full-blown Roses nearly as fine as those sent.

FROM ST. BRIGID, on the Hill of Howth, we have a charming batch of very large double yellow Primroses, surrounded by leaves of Alum Root (*Heuchera*), which seem to show them off very prettily. These double yellow Primroses when well grown, as in this case, have a high value. The blooms measure 1½ inches across. This seems the double form of the yellow Primrose, and decidedly better than the double white, which is commoner in Southern England. The flowers are of an exquisite softness of colour in this respect, far surpassing that of the strong and bold single kinds which come with them from the same garden.

LILIUM THOMPSONIANUM.—The finest specimen that we have seen of this Himalayan bulbous plant was that shown at South Kensington on Tuesday last by Mr. Wilson. It was in a 6-inch pot, and one bulb bore no fewer than seven spikes, one of which was about 15 inches high and carried forty flowers and buds, several of which were expanded. Considering how difficult it is to grow this Lily successfully, Mr. Wilson's specimen is remarkable, and it would be interesting to know what mode of treatment he has followed. The rosy pink flowers of this species are different from those of any other. We observe that the latest name for the plant is *Notholirion roseum*.

RHODODENDRON COUNTESS OF HADDINGTON.—For some time past a fine bush of this lovely hybrid *Rhododendron* has been a great attraction in the Royal Botanic Society's conservatory in the Regent's Park. The plant, about 8 feet high and nearly as much in diameter, is in perfect health, and is densely laden with large blossoms, which when first expanded are a soft pink, but at length become pure white. This plant represents one of the finest varieties we have seen of this hybrid, the flowers being much larger and the colour deeper than usual. Such a beautiful

Rhododendron as this only needs to be seen to be appreciated. It is not uncommon, but not often seen so finely grown.

THE DOUBLE SPARMANNIA which we saw the other day in flower in Messrs. Desbois and Co.'s nursery at Ghent we thought an extremely pretty plant. The flowers, produced in large umbels, as in the well-known single-flowered original, form neat miniature white rosettes, the clusters of stamens being transformed into narrow white petals. The bases of these transformed stamens are slightly stained with a carmine hue, but this does not mar the pure whiteness of the rosettes as seen on the plant. If this double variety could be flowered as freely as the type, it would indeed be a valuable garden plant, and particularly useful for cutting. It is, we observe, in most of the London nurseries.

OPEN-AIR FLOWERS sent to us from Edinburgh by Messrs. Dickson & Co., of the Pilgrimage Nurseries, include the true *Erica carnea*, which has been in full flower since February. It is much superior to *E. herbacea* in colour, size of flower, and profusion of bloom; also *E. sordida*, which succeeds *carnea*; *E. mediterranea* and its white variety, never considered so hardy as some others, but Messrs. Dickson say that they cannot be very tender, as they have withstood all the severe winters in their nursery for many years. *Menziesia empetrifolia*, a neat little Heath-like shrub, is also sent, together with *Saxifraga Wallacei*, which is just bursting into flower. With these also come a double yellow *Auricula*, seedling *Primroses*, and *Polyanthuses*; *Triteleia uniflora*, one of the prettiest and most perpetual flowering of hardy bulbs; and *Narcissus Horsfieldi*, one of the finest of all Daffodils.

PETREA VULBILIS.—The large plant of this shrub in the conservatory at the Regent's Park Botanic Garden has for the last week or two been one of the loveliest sights imaginable, and afforded as much, or perhaps more, gratification to the visitors last Wednesday than the show held on that day in the gardens. The plant is trained close under one of the low roofs of the house, and the large area which it covers is literally a mass of bloom. The racemes of flowers, mauve and violet, are from 6 inches to 9 inches long, and hang in graceful profusion. The corolla of the flower is purple, and resembles a Violet set in a large star-like calyx. In course of time the corolla drops off, leaving the staminal calices on the raceme, which keeps its colour for a considerable time. The plant has occupied its present position for some years. It is growing in a large tub placed on the stage. The essential conditions of success seem to be abundance of heat and at all times a moisture-laden atmosphere.

NOTES FROM CORNWALL.—I send you a boxful of flowers all of which were gathered out of doors this morning (25th. inst.) I fear we shall not have our usual fine show of Banksian Roses this year, the earliest buds being completely ruined by the severe weather which we had in March. The *Camellia* sent was cut from a bush planted at the western side of a high wall, but it is so hemmed in by a large Holm Oak that it never gets a glimpse of sun; there are several flowers on the bush equally good. The *Habrothamnus* is growing on a south wall at the west end of a greenhouse. The weather here is still very cold at night, and to-day we have had a fall of hail and sleet. —JOHN C. TALLACK, *Prideaux Place, Padstow*. [Notwithstanding the inclemency of the weather, Mr. Tallack sends us beautiful trusses of Banksian Roses, flowering sprays of *Habrothamnus fascicularis*, *Camellias* and *Auriculas* all gathered, as he says, from the open garden.]

CANTUA DEPENDENS.—I herewith send you cut blooms of this shrub and a few notes as to its culture. I find that it succeeds best in an ordinary greenhouse temperature planted on the north side and trained to the roof as a creeper 15 inches from the glass. Its great enemy is red spider, and if trained otherwise the soil is liable to get stagnant owing to the large amount of syringing which it requires to keep down this pest. The blooms, too, are thus shown off to the

best advantage. It thrives well in a mixture of fibrous loam, peat, and sand. Several strong shoots should be trained to the trellis, and the side shoots from these should bear flowers. After flowering, these should be pruned in to two or three buds, slightly shading the plant till it has completed its growth, after which it should be exposed to full sunshine to well ripen the wood. Under this treatment it flowers from January till the first week in May.—A. CHAPMAN, *Weston-Birt, Gloucester*. [With this came some glorious flowering sprays of this fine Chilean shrub—as fine as we have ever seen them. Though so long introduced and so beautiful, it is not half enough known. It is far more worthy of culture than hosts of plants which engage the attention of cultivators. The flowers are tubular, 4 inches in length, brilliant magenta in colour, and hang in graceful clusters from every twig.]

THE NARCISSI shown by Messrs. Barr & Son at both South Kensington and Regent's Park during the week were finer than ever, and well represented the wealth of varieties there is among Daffodils. On this occasion every section was included in the collection, and among the Ajax varieties were such beautiful kinds of Empress, Emperor, Horsfieldi maximus, bicolor J. B. M. Camm, which may be said to be the very finest of the greater sorts. Then of the Leedsi and incomparabilis group there was a host of varieties quite bewildering to those whose knowledge of Narcissi is limited. The poeticus type was never finer; in short, no such collection has ever before been exhibited, there being no fewer than 120 kinds, and most of these were represented by several bunches of flowers. The collection made a fine array of colour, but we imagine that a far finer effect would be produced if the various sections were placed in distinct groups and the bottles hid at much as possible. Much of the beauty of these Narcissi was lost by the mixed haphazard arrangement and the obtrusiveness of the ugly bottles. With the assistance of a few graceful Ferns and other greenery, a splendid display could be made by the exercise of a little taste and care.

Garden walls.—In reply to "W. C. B." (p. 365), allow me to say that I much doubt if the saving effected by using stone in place of bricks for garden walls would be such as to make the use of stone advisable, even where the latter can be had for the cost of quarrying and preparing. As a matter of course something depends on the character of the stone and its adaptability for walling purposes, and also on the value of lime in the neighbourhood, as less will be required in brick than stone walls. I have seen a stone wall faced with brick, but care is required in building to tie the work well together. Stone might be faced with cement, but that would entail considerable cost, and would require to be studded and wired when fruit trees are to be grown against it. Stone or cement faced walls have a cold, uncomfortable appearance in a garden, and beyond their use for a simple fence and for training bush fruits against I would not employ them. A 7-foot wall is much too low to give fruit trees a fair chance of extending in a way to develop their true character and bearing capabilities; 10 feet is quite low enough. As to the advisability of planting Peaches, much depends on the locality. This fruit will answer on a west wall in places where the climate is suitable. As a matter of course Peaches will be more likely to bear on a west than on an east aspect, consequent on the bloom being less likely to suffer from frosty winds from that quarter than the east. The same holds good with Plums, which I should also plant on the west side, putting Pears and Cherries on the east. If the locality is such as not to give fair promise of Peaches succeeding, I should cover the west wall with such kinds of Pears, Plums, and Cherries as were most desired, leaving the eastern side to others of less consequence. T. B.

The Garden.—General Index to the first twenty vols. now ready, strongly bound, price 12s. 6d.

INDOOR GARDEN.

DIELYTRA SPECTABILIS IN POTS.

THIS may be said to be one of the most useful hardy plants we have, and one especially suited for pot culture, though even in the coldest parts of Yorkshire it flowers freely outdoors. It is, however, of its merits as a pot plant I am going to speak. The best season to have it in flower is from February to the end of April. It is a plant that dislikes over-forcing, under which it assumes a weakly, drawn appearance. To have it in good form it should be strong and healthy, and should produce long trusses of its peculiar shaped and handsome flowers in abundance. Plants of it for forcing should be lifted from the open ground in mild weather, as if frosty both its crowns and large thick roots will be broken. When gently forced and allowed plenty of time in which to make growth the stems become strong and sturdy, and are not liable to get damaged when the plants are removed from place to place. They should, however, be staked, an operation which should not be deferred too long, or the stems are apt to become twisted and broken. For room embellishment or dinner-table decoration *Dielytrae* are very effective, or they may be arranged in masses in the conservatory. The most effective way of displaying their graceful flowering wreaths is to have the plants sufficiently elevated for the eye to view them from below. At Eastertide we have had 700 or 800 plants all in full flower at one time. Those who have a stock of it should prize it and grow a quantity of it in pots. If any injury arises, it is done after the flowering season is over. Instead of the growths made indoors being gradually hardened off, the plants are either planted out regardless of the weather, or, what is still worse, laid upon their sides and kept in an unnaturally dry state.

As regards soil, a mixture of good loam with a little sand, leaf-mould, and peat answers admirably, the last three forming about one-third of the bulk of the loam. When planted in borders the soil should be light and friable.

D. WILSON.

ANTHURIUM SPLENDIDUM.

AMONGST the numbers of new Aroids remarkable for their fine foliage that have been recently introduced to our gardens from the tropics of South America none are so ornamental as the one which Mr. Bull, of Chelsea, is now distributing for the first time under the appropriate name of *An-*

most beautiful feature of the plant is its colour—a kind of bronzy green, shaded with greens of lighter and deeper shades. Those who admire plants with beautiful foliage will welcome this one, especially as it shows its true character even in the very youngest state. It was one of the new plants shown at Ghent last week in competition for the silver cups offered by Mr. Bull, and was much admired. As to its culture, we should say, judging by what we have seen, that it flourishes in a warm, moist atmosphere, and that it is all the better if grown in a glass case in which the atmosphere could be kept close and equable.

CULTURE OF GLORIOSAS.

AMONG summer and autumn flowering plants few are appreciated more than these; the profusion of highly-coloured flowers which they produce with unfailing regularity repays all the labour bestowed on them. Any one possessing a stove may grow them provided they are not heavily shaded. We always grow ours in the Pine stoves, where they are fully exposed during the whole period of their growth. Now is a suitable time for potting them; the pots may vary in size from 6-inch to 12-inch. They should be well drained, and the compost should be used in a rough state. It should be composed of loam and peat or loam and wholesome leaf-mould, in equal portions, with one-eighth coarse sand. We have added among other things at times some old cow manure, but found no difference in the growth of the plants from its use. The tubers may be either laid on their sides or placed with the end furthest away from the old tuber uppermost, and in either of these cases they must be covered more than 2 in.

*Anthurium splendendum.*

thurium splendendum, a small state of which is represented by the annexed illustration. In the form, size, and colour of the foliage it is distinct from any other in cultivation; it is therefore a valuable addition to stove plants. The stem is short and thick, and even in a small state produces several leaves. These are heart-shaped, and grow to about twice the size of those here represented. The upper surface between the veins is peculiarly puckered, as if blistered, and the under surface is traversed by prominent veins. The

deep. If the compost is fairly moist at the time of potting, they will not require any water until they have made a few inches of growth. Care must be taken that slugs do not get at them and destroy the young growths, for if their points are injured at any time they will be of little use for that season. Where the stove is heavily shaded, space might be left at one end where they could be placed near the glass, or strings might be stretched along the bottom at right angles with the rafters. No shading need be used over where they are

trained; by having them on strings they can be easily removed if necessary and placed on a trellis so as to be ready for decorating the conservatory in August. I have only grown *G. superba* and *Planti* or *virescens*. The latter seeds freely.

PROPAGATION may be effected by means of seeds, but oftener by division of the tubers. When seeds are employed, they may be sown as soon as they are ripe, and if properly matured they germinate freely. It is best to allow them to remain in their seed pots for the first year; half a dozen seeds in a 4-inch pot will be enough. The following year they should be potted in the same compost as that used for older plants, three tubers being placed in a 6-inch pot. Towards the end of September the foliage will assume a yellowish hue, thus indicating that their time of resting is approaching. They will not then require so much water, but they must nevertheless be supplied with it when dry. Anything like forced rest must be avoided. When the leaves and stems are withered, water should be entirely withheld and the pots placed on their sides in a temperature of not less than 50°. It is noteworthy that *Gloriosas* are not liable to be attacked by disease or by insect pests, i.e., if ordinary attention be paid to them. If permitted to get dry a few times in the midst of growth, red spider will probably make its appearance, but it can be got rid of by a diligent use of the syringe and a sufficient supply of liquid manure to encourage robust growth.

W. P. R.

HYACINTHS—THEIR CULTURE AND SELECTION.

No garden can be considered furnished with spring flowers that contains no Hyacinths. Almost everybody grows them, but all do not succeed in growing them even fairly well. Good spikes cannot be produced unless the best bulbs are purchased. What we in this country have to do is simply to develop the spike formed in the bulb the previous season in the bulb gardens in Holland. We cannot place more flowers on the spike than the number already there before it came into our possession. It will thus be seen how important it is to purchase bulbs that have been well grown and thoroughly matured. In selecting bulbs it is not well to lay too much stress upon their being well formed; indeed, a rather extensive experience confirms me in the belief that the ugly, misshapen bulbs are the most likely to produce good spikes. Some bulbs seem as if they were partly split open by some internal force. This is doubtless the result of spike formation inside, and it is a sure sign that the spike will be a good one.

THE POTTING MATERIAL ought to be very rich and porous. I use a compost of two parts turfy loam, one of rotten cow manure, one of leaf-mould, and one of sharp sand—sea sand is best. There is a right and a wrong way in potting the bulbs. The wrong way is to fill the pot with the potting material, and then to press the bulb into it. This causes the soil underneath the bulb to be so firm, that during the process of root formation the bulbs are forced out of the soil. The right way is to open a space in the soil rather larger than the bulb, put in a little sand, then close the compost round the bulb, pressing it in rather firmly. The top of the bulb should just project out of the soil; place a pinch of sand over it. When the bulbs are all potted they should be placed out of doors on a dry bottom of coal ashes. Cover the pots over with Cocoa-nut fibre refuse, or leaf mould answers well for the purpose. The best place to plunge the pots is an open position where they are fully exposed to atmospheric influences. They are sometimes put under the stages of plant houses, but that is not a good place for them. The drip from plants above is likely to make some of them too wet, while others get too dry. Such treatment is almost sure to cause an unequal growth and many weak and badly developed spikes. Another frequent cause of failure, especially with the earliest flowering plants, is to take them into the forcing house before roots have been

formed or not sufficiently formed to support well the rapidly growing spikes and leaves.

FORCING.—The Hyacinth is very easily forced, and can stand a moderately high temperature, but the bulbs must be early potted and placed out of doors in plunging material until roots are formed, and it is best not to hurry the plants too much into growth at first. Start them with a low night temperature, and gradually increase it as the plants show signs of growth. A very good way of promoting root development is to plunge the pots in a very gentle bottom heat; with the aid of this they can be pushed on in a higher temperature than would otherwise be possible. The best spikes are usually obtained later in the season. Roots are formed very rapidly out of doors about the last week in September, and the spikes are usually to be seen about an inch above the crowns by the second or third week in January, when they may be moved indoors. If it is intended to publicly exhibit them at the spring exhibitions which are usually held in March, about the end of that month, extra care must, of course, be taken with them. They should receive greenhouse treatment for a month or six weeks after they are taken into the house, and if it is necessary to push some of the late flowering varieties on a little faster it is easy to do so by taking them into a warmer house for a few days. For instance, one of the best Hyacinths—King of the Blues—flowers later than the others, and requires to be placed in a warmer house to get it in at the same time as the earlier flowering varieties. Neat wire supports are the best to keep the spikes in an erect position. The wire should be bent where it enters the mould to avoid injuring the bulbs. In some cases the bells are placed too closely on the spikes and they cannot develop themselves, forming a crowded mass merely of half-opened flowers. It surely agrees with common sense as well as with good gardening that the surplus bells should be removed with a pair of scissors to allow the spikes as well as the flowers to develop themselves perfectly. Thinning the flowers, as well as arranging them on the spikes, is allowed to an exhibitor, and is a part, a necessary part, of the cultivation of the Hyacinth. The question of tying two spikes together very closely, so that they are made to appear as one, ought not to be permitted by an exhibitor. It is sometimes done, and I remember judging at an exhibition where this was done, the exhibitors vieing with each other as to who would do the neatest work. Another dodge I found last year at an exhibition where I was judging. It was late in the season, and the Hyacinths had been kept back by shading until the leaves had become much more elongated than was desirable. As it is usual to plunge the pots in which the Hyacinths were grown in a larger pot, and to cover the surface over with green Moss, advantage was taken of this to double the leaves in the way careful mothers tuck their children's frocks to shorten the skirts for a time, the tuck in the Hyacinth leaves being covered by the Moss. The deception being discovered in time, the exhibitor was disqualified in several classes. One is frequently confronted with the question, what becomes of all the

NEW HYACINTHS that are introduced and publicly exhibited year after year? I have attended every exhibition of Hyacinths that has been held in London for the past fifteen or twenty years, and can say with confidence that more really good new Hyacinths have been exhibited in that time than are to be found in the best trade catalogues of the present day, and yet not one in twenty of those new Hyacinths are to be found in the trade lists. The Messrs. Veitch, of King's Road, Chelsea, have exhibited far more new Hyacinths in that time than all the other trade growers together. Since the year 1871 they have received no fewer than sixty first-class certificates for new Hyacinths, viz., in 1871 one for Princess Louise, a single white variety, with large, well-formed bells; in 1873 one for Mazzini, single blue; Baroness Van Tuyl, and Marie. The year 1874 brought a grand display of new Hyacinths: Anna, pinky white, a splendid variety; Plimsoll, single white;

Sir G. Wolseley, single blue; and Cavaignac, single blue. From the Royal Botanic Society this firm received awards for Anna; Sir G. Wolseley; Von Schiller, single blue; and Minister Thorbeck, single white. In 1875 Etna received a certificate from the Royal Horticultural Society. In 1876 Sultan, a distinct single violet, was certificated; The Shah, single blue; and Golden Lion. In 1877 Orange Queen, Marquis of Lorne, Globosa, and Queen of Lilacs were certificated; in 1878 King of Blacks, Grand Maître (single blue), and Queen of Blues. The year 1879 was a good year for them. The Royal Horticultural Society certificated Salmon King, King of Reds, and Leviathan; the Royal Botanic Society Duke of Connaught, single blue; Duchess of Connaught, a fine pale blue or lilac; Duke of Norfolk, single blue; King of Reds; Leviathan, single white; Royal Blue; Lord Derby, single red; McMahon, single yellow; Prince Imperial, and Salmon King. In 1880 the Royal Horticultural Society gave a double first to the single blue Cavaignac, while Queen of Yellows and Electra, single blue, received first-class certificates. In that year the Royal Botanic Society certificated Cavaignac, Queen of Yellows, Distinction, single red, and Capt. Boyton, single red. In 1881, Primrose Perfection and Magnificence were certificated. In 1882, Enchantress, single blue; Delicata, pale pink; Leo, double pink; Challenger, deep red; Delicata, Charles Dickens, Surprise, and Duke of Albany were certificated. In 1883 first-class awards were made to Pink Perfection and Souvenir de J. H. Veen, while the Royal Botanic Society honoured these two and also Empress of India with certificates. Besides the above the same firm has during that time exhibited at least 200 of what may be termed really good varieties.

A SELECTION of the very best varieties that are to be found in the trade catalogues would comprise the following, all of which are adapted for exhibition, and of course if a variety is good for exhibition it is also good for the drawing-room, greenhouse, or conservatory: Single red—Cavaignac, Fabiola, Garibaldi, Gigantea, Lady Palmerston, Lina, Lord Macaulay, Linnæus, Princess Helena, Solfaterre, Sultan's Favourite, Von Schiller, Vurbaak. The only double red varieties I care to grow are Duke of Wellington and Koh-i-noor. The best single blue varieties are, Argus, Baron Van Tuyl, Blondin, Charles Dickens, Czar Peter, De Candolle, Grand Lilas, Grand Maître, General Havelock, King of the Blues, Lord Derby, Lord Palmerston, Marie, Mimosa, Prince of Wales, and Sir John Lawrence. Of double blue sorts, I care only for the deep indigo blue Laurens Koster and the pale blue Van Speyk. Mauve and magenta are Charles Dickens, Sir Henry Havelock, and Haydn. Single white varieties should comprise Alba maxima, Baroness Van Tuyl, La Grandesse, l'Innocence, Mont Blanc, Queen of the Netherlands; Snowball has the best formed bell, but it is not a good spike; Grandeur à Merveille is white with a rose tinge. Single yellows—of these I grow only Bird of Paradise and Ida.

J. DOUGLAS.

Fine-foliaged Begonias from seed.—

All these Begonias are increased without difficulty by division or by cuttings made of the leaves, so that it is by no means necessary to raise them from seed; yet, by the latter method, although nothing may be obtained superior, or even equal, to some of the older kinds, it is very interesting to watch the young plants gradually developing their adult characters, for the change that takes place in them is very great. My seedlings are obtained from home-sown seed—that is, having three or four distinct varieties in bloom at the same time I intercrossed them one with the other, and when the seed was ripe it was sown in a shallow pan without being covered in any way, except a pane of glass laid over it, till germination took place. So treated and placed in the stove, the seedlings came up quickly and in great profusion, and as soon as large enough to handle they were pricked off. After that they grew rapidly, and were soon established in little pots, when a glance over them at that time gave great promise of

FRUIT GARDEN.

TOO SMALL VINE BORDERS.

VINE borders, in my opinion, as at present formed are much too limited as regards surface space; they are too narrow and often too deep. It is a waste of time and material to excavate to a depth of 3 feet, and to provide an expensive system of drainage. In practice that is unnecessary. What is wanted is more surface space. The most fruitful Vines are those that have unlimited root-run. We ought, therefore, to prepare Vine borders in such a way that when planted they will last a lifetime, and in many cases it is possible to do so. To accomplish this we must, however, step out of the beaten track. We need not look far for evidence to show that restricted Vine borders do not promote productive and long-lived Vines. In eight cases out of ten, when the Vines have reached the age of twenty years they are worn out or rather prematurely exhausted from want of more root room. If we look at the rambling character of the roots, we have the key to the conditions required to sustain Vines in a vigorous and fruitful state, and, given these conditions for the roots and proportionate space for the branches, there is no reason why, except in the most unfavourable situations, a house of Vines, when once planted, judiciously cropped, and otherwise well treated, should not keep fruitful for forty or fifty years, instead as now, in restricted borders only from fifteen to twenty years. I do not say that Vines do not produce good crops of Grapes in these narrow borders. My argument is, that when a good fruitful state is arrived at it should go on for a much longer time than it now does, but that is not possible with a limited root-run. Where old Vines remain in vigorous health and fruitfulness it is generally acknowledged by those who manage them that the roots have long since escaped from the limits at first assigned to them. Therefore, can more conclusive evidence be offered in favour of more root room? I have yet another objection to make to

LIMITED BORDERS, especially those where the situation is low and the staple soil of the place of a cold, ungenial character. In this, as in all other positions the roots refuse to be confined: they find their way into the unsuitable soil below, and consequently in a few years the Vines get into an unhealthy condition. This could be prevented by giving more surface space; for although it is not possible always to prevent a few large roots finding their way into undesirable quarters, it is the natural character of the plant to seek principally for its food near the surface, where it can find warmth and moisture. If the space is limited, ill-health shortly follows. If that be not so, how are we to account for the fact that in eight cases out of ten there is not a viney to be found in the country in a satisfactory condition that has been planted more than twenty years? This may be denied, but the denial must be supported by proof. I maintain that for general purposes we do not want rich and deep borders limited to a certain size that will furnish a bountiful supply of food for the roots for a few years and then become suddenly exhausted. The Vine is impatient of restriction both as regards root and top, and when placed under suitable conditions it is able to remain fruitful for a great length of time. I therefore hold to the opinion that in providing borders of limited extent we do not place the Vine under conditions favourable to its attaining a fruitful condition in old age, and I base my argument on the principle that if you give the roots sufficient surface space, even if the subsoil be of an unkindly character, there will be sufficient roots maintained in a healthy condition to keep the Vines in health and fruitfulness for a number of years (that is supposing that some of the roots should find their way into bad soil, which they are not likely to do to any extent if they have room to extend in better quarters).

WHAT KIND OF BORDERS, then, are necessary for promoting long-lived and fruitful Vines? I have already in a great measure answered this question, but I should like further to say that I want to see restricted root space done away with altogether.

Instead of having narrow borders and a prominent walk in front of them, the roots should have a long run before them in one of the quarters of the kitchen garden, or some other favourable position in which they are not in any way confined, within 60 feet or 70 feet of the house. This space need not be wholly unoccupied, but the half of it nearest the house should remain uncropped. With so much surface space, deep borders would be unnecessary. It would not indeed be needful to make borders more than 2 feet deep, and only from 10 feet to 12 feet wide. If beyond this point the soil to a depth of 15 inches or 18 inches is fairly good, the Vines would take no harm; on the contrary, they would revel in it if its composition is in any way different from that of the border, *i.e.*, if the roots can only keep near the surface. It is clear to me that we hardly recognise the benefit that a warm border affords the roots of Vines. I feel satisfied that if it were possible to give the roots sufficient water we could not do better than cover our outside Vine borders with flagstones; the warmth generated by these stones would bring the roots near the surface and prevent them from going deeper into ungenial soil. I have quite recently had ocular proof that such would be the case. In making some alterations in a large house in which one-third of the interior is occupied by a border for Vines and the remaining space covered with square tiles, I found on taking up the floor formed with the tiles that under them there was a perfect network of roots from one end of the house to the other. They had made their way either through or under a $4\frac{1}{2}$ -inch brick wall, and were evidently enjoying the warmth and moisture obtained through the tiles. It must be understood that to create internal atmospheric moisture for the Vines the floor of the house is kept constantly damp during the summer when they require moisture, and it is very certain, owing to the poorness of the soil under the floor, that there was nothing there to induce the Vines to root so freely except the warmth generated by the tiles and the moisture resulting from the constant damping of the floor. This covering of the surface would, however, only do good in the case of restricted borders. I mention my own experience in respect to this matter to show that, with plenty of surface space, the roots will come there in search of warmth and be benefited thereby.

J. C. C.

SMALL-FLOWERED PEACHES BEST FOR FORCING.

THOUGH, as a rule, we rarely fail to get a good set of fruit on all the trees of our indoor Peaches, yet we have occasionally had partial failures, and particularly in our earliest house; year after year in a larger or lesser degree has this occurred, and we have been much puzzled to discover a reason, seeing that all the usual remedies against such mishaps have been scrupulously carried out—such as never allowing the border to get too dry, preventing the overcrowding of shoots, which hinders perfect maturity, and taking care not to apply too much fire-heat on first starting to force. This last is a condition which must be credited with the cause of more failures in Peach forcing than all other causes put together. In our case all these dangers, and more, have been guarded against, and still on some trees the fruit sets very thinly. This year, however, we think we have really made out the right position of the danger signal, and mean to avoid failures in future. I daresay some readers will marvel when it is said that large flowered Peaches constitute the "bogie," at least, in the earliest house, but such is the fact; every tree of the small flowered section sets freely, the large flowered ones only fail, and on close examination the reason why of this is plain enough—the small flowered have always a superabundance of pollen; the large flowered lack this, so that henceforth none but small flowered varieties will be grown in the earliest house. In a late house both large and small flowered kinds set equally well, the advanced season, sunshine, and a drier atmosphere conducing to the free setting of varieties most destitute of

something new. In some the leaves were of a dazzling silvery whiteness; in others I had the same ground colour, with bright green punctures; in some they were regularly striped and banded, or clouded and freckled in various ways; but after a time, as they assumed their adult forms, the promise of novelty disappeared, and the foliage partook of the character of ordinary kinds. Such being the case, it may be said there is no advantage in propagating them in this way; but, apart from any other considerations, the seedlings, when in 4-inch or 5-inch pots, make pretty little specimens, and are at that size very useful for decorative purposes, such as where grouping is employed, for using in conjunction with Ferns and similar subjects, to finish off the edges of the groups, or to carpet the ground underneath taller plants.—ALPHA.

Cantua dependens.—I have had a plant of this on a rafter in a curvilinear greenhouse for these last twenty years, and every spring it has formed a waving arch of floral beauty, the point of every shoot carrying pendulous bunches of rose-coloured flowers in great abundance. The plant grows in a border of common loam along with Roses and climbers, the roots of course being under the side stage, and the hot-water pipes are frequently deluged with water from the pathway. The *Cantua* is very liable to red spider; therefore the syringe should be freely used. It is a plant of vigorous growth and will soon reach the top of a 20-foot rafter, but I prefer *Cantua bicolor* to *C. dependens*, the flowers of bicolor being a rich, reddish yellow or bronze, and consequently very attractive. It also grows and blossoms freely when planted out. The flowers are dispersed along the young shoots, and not in such large terminal bunches as in the case of *C. dependens*. I find both to be very useful for drawing-room decoration.—K. H.

A floriferous Stephanotis.—A few days ago in looking through Sir Fred. H. Bathurst's gardens at Clarendon Park, near Salisbury, I noticed, not for the first time, in a three-quarter span-roofed stove a truly grand plant of *Stephanotis floribunda* growing in a box 2 feet long, 20 inches deep, and 18 inches wide, standing on the end of a stage; the shoots were trained longitudinally under the apex of the roof, and about 4 feet or 5 feet wide on each side the entire length of the stove (about 25 feet). And had the welfare of the luxuriant and well-flowered plants of *Gardenias* planted in the bed underneath not been cared for, there were sufficient *Stephanotis* shoots to cover the whole roof. That the treatment which this plant receives from Sir Frederick's gardener, Mr. Warden, is in every respect congenial to its special requirements, is amply shown by the profusion of dark green leaves with which the shoots are clothed, and by the grand trusses of flower with which they are furnished—even to the points of the young shoots—these and the *Gardenia* blooms quite scenting the air not only in the house, but also that immediately surrounding the house when the atmosphere is undisturbed by wind. Your readers will understand that a plant having such limited root space as that under notice requires and receives liberal treatment in the way of top-dressings and copious and frequent supplies of weak manure and soot water, to the effect of which and its judicious application may in a great measure be attributed the fine condition in which the plant now is and its general disposition to bloom profusely. *En passant*, I may be allowed to remark that cut flowers and plants are in great demand at Clarendon for table and house decoration, and that Lady Bathurst, who has a good knowledge of plants and flowers, takes great interest in floral decorations and gardening generally.—H. W. W.

Anthracite coal.—I have much pleasure in informing "J. H." that the best anthracite for heating purposes is to be had from Llanelli and Burry Port. It is the only pure anthracite, and can be had from J. & C. Harrison, 66, Mark Lane, London, and Llanelli. I have used the above coal for several years and have found none equal to it.—J. J. T.

pollen. The following we have tested as reliable forcing varieties, being alike good bearers, sure setters, and producers of fruit of fine quality; they are named in the order in which they ripen, and are all small flowered, viz., Early Louise, Dagmar, Magdala, Crimson Galande, Bellegarde, and Royal George. W. W. H.

VINE PROPAGATION.

As there has lately been some quibbling over certain modes of Vine propagation, more particularly as to whom we are indebted for originating the turf plan of propagation, it has occurred to me that perhaps I, too, might become famous as an inventor if I could but overcome my natural modesty, and bid for greatness by the record of my own doings in this direction; so here goes, sink or swim. Well, in March of last year I determined on pulling up some old Vines and replacing them with young ones, but then I had no plants nor the wherewithal to buy any, and "to beg I was ashamed." Very fortunately though I had saved the prunings of old Vines, which at the time of pruning had been tied together, and their ends put in soil behind a north wall; these were at once cut up into eyes, put in pots, and plunged in frames after the usual mode of propagation. The border—an inside one—was at once made, and consisted of two-thirds—top spit—of freshly-dug loam, the other third being $\frac{1}{2}$ -inch bones, charcoal, mortar rubble, and horse droppings, the whole being thoroughly mixed together, and well pounded into position; in less than a week after being made up a bottom heat thermometer placed in the border registered 85°. Such a favourable condition for starting the Vine eyes could not be lost, and so I transferred the eyes from their snug quarters in the pots and frames to still more snug quarters—the new border, and over each one placed a small bell-glass. These were left over till the eyes had rooted, which they did in three weeks, and grew away with all the vigour of fully-established Vines. There, now, is the latest idea in Vine propagation. I have secured no patent; all are at liberty to practise it, and may they meet with the same reward that I am likely to do this year, namely, an abundant crop of Grapes. W. W. H.

Fruit prospects in Somerset.—So far as I am able to judge from the appearance of fruit trees in the middle of April, there is nothing very alarming to report. The Apricot crop will, undoubtedly, be a thin one, as all the early flowers were killed by the severe March weather, and this even under a wide glass coping and Frigidom curtains in front. Still, I think the later blossoms which opened will give us a few fruits. Early flowering and tender Pears were a good deal injured by the frosts in March, especially such sorts as Marie Louise, Brockworth Park, and Berré Clairgeau, but a few sorts are now opening stronger, and, therefore, more promising than I expected. I do not think the Plum crop is in any way hurt as yet. Green Gages are now flowering abundantly, and this is almost the only kind of Plum in blossom yet, a sufficient proof of the lateness of the season. Gooseberries are very promising so far, but both Black and Red Currants are breaking very unevenly. Strawberries, a fortnight ago, looked as if a fire had passed over them, every leaf being withered into tinder, but now they are showing signs of fresh animation. Apple trees have in no way suffered, but rather benefited by a cold wintry March, as it has kept them back; so far as one is able to judge, there is a full average promise of bloom on most of the trees.—J. C. C.

The late cold weather.—In a late number of the *Journal des Débats*, one of the leading French newspapers, there are some striking remarks by M. Henri de Parville on the late burst of cold weather which it may be of interest to remember. "Winter came this year," it says, "in March. From the 7th to the 15th the cold was very great, even in the south of France, in Italy, and in Algeria. The lowest temperature was on March 11; on

that night the thermometer fell at the Parc de Saint Manr to 7° Cent., or 19° Fahr. During December, January, and February the temperature was 2° above the average, though less warm than in 1876-77, when it was 4° above the average. It is not the first time that this unusual cold has occurred in March, for it is the fifth time since the beginning of the century that the severest cold has come in that month. The lowest recorded temperature in March was in 1796, when in Paris the mercury fell on March 7 to 8° Cent., or 17° Fahr. In 1807 on March 12 3° were registered. In 1825 the lowest temperature of the year was again on March 17 (St. Patrick's Day)—5° Cent., or 23° Fahr. In 1863 on March 1 the cold was unusual, 2° Cent., or 25° Fahr. being recorded." These figures show how curiously anomalies of temperature repeat themselves, and add to the probability that the more carefully records of climate are kept the more it will become apparent that no great alteration in the climate of Europe has taken place, but that considerable variation has been at all times the case.—BRINSLEY MARLAY.

TREES AND SHRUBS.

THE BLACK MOUNTAIN FIR.

(PICEA CEPHALONICA.)

THIS beautiful and distinct Fir is well adapted for planting as single specimens on lawns. It is also very effective when planted along with other conifers of different shades of colour and habits of growth. It is a native of the mountainous districts of Cephalonia, where it attains an average height of about 60 feet. Unfortunately, in early life in this country it is liable to be cut down by late spring frosts, yet by a proper selection of soils and sites I have been successful in growing some fine specimens of it. For many years after its introduction into this country it was chiefly propagated by grafting it on the common Silver Fir, and as both trees start into growth at the same time in spring, the scion and stock unite freely, and in this way many fine trees have been produced. For a great number of years I have, however, raised it entirely from seed, of which the trees, after attaining a medium size, produce abundance. It should be collected in autumn, extracted from the cones, and sown the following spring. In selecting a seed bed, preference should be given to a light rich soil, shaded by trees or shrubs from the morning sun, so as to screen the young plants from its rays after late spring frosts. The ground should be thoroughly pulverised and formed into beds about 4 feet wide. The seeds should be sown broadcast and evenly on the surface, and a light roller should be run over the bed, so as to settle them down in a uniform manner, finishing by covering all evenly over with fine soil. When the young plants begin to appear above ground a few evergreen branches should be stuck in here and there to screen them from frost. When they have attained a height of some 5 inches or 6 inches they should be planted out in nursery lines in the same manner as that recommended for *P. nobilis*, the only difference being that they will require, as has just been stated, a little protection in spring.

THE SOIL most suitable for this conifer is good clayey loam, rich in organic matter, thoroughly drained, and resting upon a cool clayey subsoil. It is also quite at home when planted on well decomposed peat bog, mixed with a little ordinary soil. When planted as a single specimen on a lawn, the site, if possible, should be exposed to the north; this will assist in retarding its growth in spring and lessen the risk of its being cut down by frost. It is exceptionally well adapted for planting in cold, bare, open places among deciduous trees, where it is desirable to establish contrast and variety. In planting it in such positions the ground should be thoroughly trenched and all tree roots and dead stumps should be extracted. If this can be done a year before the trees are planted, so much the better, as the ground will be much improved by being broken

up and left in a rough state exposed to the weather for that period.

IN PLANTING spread the roots well out and keep the plants rather above than below the level of the surface. They should then be fenced, in order to protect them from hares and rabbits. For this purpose I have generally used wire netting, which is best and cheapest in the end. It may be 30 inches high, 2-inch mesh, wire gauge 17, and erected in a circular form round the plant at a distance of fully 1 yard from the stem, and fastened to small, upright posts. Should any Ash, Elm, Sycamore, or Birch trees be growing in the immediate vicinity of the Conifers, a deep, narrow trench should be cut at the outside of the wire netting to prevent the roots of these from robbing the young plants of the Picea. These trenches ought to be kept open for several years—say until such time as the plants fill the cages; the latter may then be removed and the trenches filled up, as the young trees ought by that time to be thoroughly established. This tree naturally assumes a dense spreading habit of growth, in consequence of which it is not liable to get drawn up too much when planted in such positions. After it has attained a height of 5 feet or 6 feet I have seldom seen it injured by frost, and when planted among other trees they afford all the protection necessary for its uninterrupted development. When it has attained a height of some 40 feet or 50 feet it has a great tendency to produce several strong side branches near the top, the terminal points of which curve round and produce an upright leader, which gives the tree a peculiar appearance. I have sometimes tried to repress this growth by breaking off the terminal bud, and sometimes by cutting back the branch in order to throw the sap and strength of the plant as much as possible into the leader; in this, however, I have only been successful to a limited extent, the trees still being inclined to have their own way. J. B. WEBSTER.

FLOW OF SAP IN A BIRCH.*

BENEATH a white Birch tree growing in my garden I noticed, the other evening, a very wet place on the gravel path the water of which was obviously being fed by the cut extremity of a branch of the Birch about an inch in diameter and some 10 feet from the ground. I afterwards found that exactly fifteen days ago circumstances rendered necessary the removal of the portion of the branch which hung over the path, 4 feet or 5 feet being still left on the tree. The water or sap was dropping fast from the branch, at the rate of sixteen large drops per minute, each drop twice or thrice the size of a "minim," and neither catkins nor leaves had yet expanded. A bottle was at once so suspended beneath the wound as to catch the whole of the exuding sap. It caught nearly 5 fluid ounces between eight and nine o'clock. During the succeeding eleven hours of the night, 44 fluid ounces were collected, an average of 4 ounces per hour. From 8.15 to 9.15 the following morning very nearly 7 ounces were obtained. From 9.15 to 10.15, with bright sunshine, 8 ounces; from 10.15 until 8.15 in the evening, the hourly record showed that the amount during that time has slowly diminished from 8 ounces to a little below 7 ounces per hour. Apparently the flow is faster in sunshine than in shade, and by day than by night. It would seem, therefore, that this slender tree, with a stem which at the ground is only 7 inches in diameter, having a height of 39 feet, and before it has any expanded leaves from whose united surfaces large amounts of water might evaporate, is able to draw from the ground about 4 litres, or seven-eighths of a gallon of fluid every twenty-four hours. This soil had only an ordinary degree of dampness. It was not wet, still less was there any actually fluid water to be seen. Indeed, usually all the adjacent soil is of a dry kind, for we are on the plateau of a hill 265 feet above the sea, and the level of the local water

* Abridged from a paper read by Prof. Atfield, F.R.S., at an evening meeting of the Pharmaceutical Society, April 4, 1883.

reservoir into which our wells dip is about 80 feet below the surface. Whether or not this little experiment throws a single ray of light on the much debated question of the cause of the rise of sap in plants, I must leave to botanists to decide. I cannot hope that it does, for Julius Sachs, than whom no one appears to have more carefully considered the subject, says, at page 677 of the recently published English translation of his textbook of botany, that "although the movements of water in plants have been copiously investigated and discussed for nearly 200 years, it is nevertheless still impossible to give a satisfactory and deductive account of the mode of operation of these movements in detail." As a chemist and physicist myself, knowing something about capillary attraction, exosmose, endosmose, atmospheric pressure and gravitation generally, and the movements caused by chemical attraction, I am afraid I must concur in the opinion that we do not yet know the real ultimate cause or causes of the rise of sap in plants.

NOTES.

THE TENBY DAFFODIL.—Of all the many forms of Daffodils now in cultivation this is one of the best. Our illustration gives a good idea of the size and form of the flower, but of course no idea of the rich intensity of its yellow hue. It is very hardy, of dwarf, robust habit of growth, and it blooms very early along with *N. nanus* and *N. maximus*. It is supposed by nearly all authorities, both ancient and modern, to be a native of Spain, but it is abundantly naturalised near Tenby, in Wales, and, as I am recently informed, it has existed in Ireland in one spot near Gorey, in Co. Wexford, for at least the past sixty years. We may not be able to clear up the exact

Tenby Daffodil (*Narcissus obvallaris*).

time of its introduction from its native country, nor whether it came to this country direct or otherwise, but it still remains to us a fact that so good and showy a Daffodil is plentiful and easily cultivated in all soils and localities. I consider it equal to any other Daffodil as regards beauty, and well worth growing in quantity along with *N. maximus*, *N. Horsfieldi*, *N. Emperor*, *N. princeps*, *N. moschatatus*, and *N. cernuus*—all Daffodils of irreproachable value in most gardens.

A SUNNY APRIL DAY AMONG THE DAFFODILS.
—Waving masses and heds, borders, and great

quarter-acre plots of Daffodils dancing in the sunshine and showing delicious glints of colour from cup and perianth as they tremble and wave and nod their graceful blossoms and buds in a sea of glaucous leaves. What fresh life and healthy vigour and graceful beauty! What Protean variety, moreover, is there not among these new seedling Narcissi! Form and colour for the florist, artist, and gardener alike; variety for all tastes, until now-a-days the old common Daffodil of the meadows has well-nigh solved the problem of pleasing all alike in some sort, and hence its growing popularity as a thoroughly hardy and graceful flower. Oh, Proserpine! thou didst not well. The Proserpines of our day love and treasure their flowers too well to lose them.

YESTERDAY I was out in Barr's bulb grounds at Lower Tooting just when Narcissi were at their freshest and best, and enjoyed their beauty thoroughly. Every day new varieties open their eyes to the sun. Of the newer and rarer kinds *N. Backhousei* is noteworthy, a sturdy little *N. bicolor* having a sulphur perianth and a golden trunk. One of the most distinct of all the *N. incomparabilis* group is *N. Barri albidus*, one of the Leeds seedling kinds. It is quite dwarf, not a foot in height, bearing its nodding sulphur blossoms among its erect glaucous leaves in a pretty modest way. *N. Barri sulphureus* is dwarf like the last, but with much darker blue-green leaves, and the flowers are sulphur with a warm orange cup. Amongst the Ajax or Daffodil section Sam Tisdale is one of great beauty, with a yellow perianth and great expanded trumpet of a rich yellow hue. Among the pale or sulphur Daffodils William Goldring is a long, slender, and graceful flower in which the pert stiffness of the wild Daffodil is lost and a lissom gracefulness acquired instead; as a cut flower it is very pretty. Among the large Peerless race Frank Miles is unique for size and beauty. During the next two or three weeks this collection will afford a great treat to all lovers of Daffodils.

ANEMONE CERULEA.—Among seasonable hardy flowers the Parsley-leaved Anemone is just now very pretty in its way, bearing bluish purple cups on stout, erect stalks, which rise from a little meadow of finely-cut dark green leaves. This plant in a way resembles *A. coronaria*, but is yet in appearance quite distinct. With it, for company, one may do worse than associate *A. coronaria* var. *The Bride*, a soft satin-like white flower with a greenish centre—indeed, not unlike the rare *A. alpina* in blossom, although with pale green *A. coronaria*-like leaves. Both these varieties are so much gain to all who love and cultivate the early blooming Windflowers. They are of Continental origin, and both grow well on well-enriched, deep, loamy soils. I complained to an old gardener the other day that Anemones did not attain their highest vigour on our light sandy soil. "Ah," said he, "all Buttercups like a bit o' clay to take a hold of with their roots," and so I find it; nearly all the Ranunculaceae flowers, "Buttercups," as my old friend said, like a bit of good strong loam to grow and luxuriate in.

FICARIA GRANDIFLORA has for weeks been very effective, throwing up in quick succession its shining golden stars, each as large as a crown-piece. Its heart shaped leaves are pretty in form and of glossy texture, and seemingly even more tender than are the flowers, since, while the latter are fresh and fair, the leaves have suffered from frost-bite and scathing east winds. Planted in bold masses or in little colonies on a sheltered border, it is most effective, blooming along with, or even in advance of, the earliest Daffodils, while this showy Buttercup is none the less handsome if contrasted with the larger Snowdrops, *Chionodoxa*, *Iris reticulata*, or with Hellebores and Hepaticas of various colours, all of which belong to that class of early-blooming plants which love all the spring sunshine they can get in our climate, provided shelter be also afforded them.

NARCISSUS CERNUUS, a very pretty white Daffodil, sometimes called *N. albicans*, comes to

*Narcissus cernuus*.

me from Tyrone, and I saw it yesterday with Mr. Barr, who says he does not tell strangers what he considers its true name to be. Suffice it to say, he at present knows it as the Irish *N. cernuus*. It is a pretty thing, as our illustration shows it to be, with a high-shouldered perianth a trifle shorter than the trunk or corona. Rather dwarf in habit, its flowers nod gracefully on a slender fluted stalk 6 inches to 9 inches in height. For cut flowers it is a gem of the first quality. Just at present, I am told, all the white Daffodils are in a chaotic state of confusion as to names, but Mr. Barr now thinks he is in a fair way of rectifying former errors and discrepancies which are to be found in books and among figures. I am inclined to think that formerly authorities were satisfied with such evidence as cut specimens or even dried plants afforded. Now one must grow and study the living plants side by side for years ere any really satisfactory, or even trustworthy, conclusions can be drawn as to their affinity.

CROWN IMPERIALS.—All plants of noble port, in fact, giant Snake's-heads or Fritillaries, bearing great leafy tufts on stems 2 feet or 3 feet in height. From below the terminal tuft of deep green leaflets dangles a circle of great Lily-like flowers, yellow or orange-red, as the case may be. Under extra good culture a double whorl of flowers may be now and then produced, but I have never yet found the crown-upon-crown variety which is said always to produce a two-storied inflorescence. Well grown in rich strong soil, no plants are more noble in growth from the earliest pushing of the strong shoots though the earth in February or March to their blooming time in showery, or what should be showery, April. We have here three kinds—the red and the yellow with green leaves, and the bright red form with golden margined foliage; also a giant variety 4 feet in height. Someone once promised to send me a silver variegated variety with pale yellow blossoms, but something happened and the plant never arrived. The peculiarly foxy odour of all these plants is a little against their being planted quite

near to the house, but they show best and are best fitted for sheltered nooks and corners among shrubs or in plantations in deep rich soil.

VERONICA.

PLANT NOMENCLATURE.

THE object of my previous remarks on the above subject has been gained by Mr. Burbidge's reply (p. 362). He says: "It is not a question as to whether Latin or English names are the best, but as to whether both Latin and English names together are not better than either used alone." Precisely so; but if he will take the trouble to read my letter again he will see that my protest was directed against the growing habit of using but one, and that the English name of plants. This, I ventured to say, was "superseding" the scientific name. If he can show that my use of the word is wrong, or if he can point out a better, I shall then accept his correction. I never spoke, as he seems to think, of "suppressing" the scientific names. I did not imagine that Mr. Burbidge would for a moment entertain such a thought; nor did I in any way identify Mr. Burbidge with the practice of which I, and others also, complain; but when I find in a paper, to which so many look for information, mention made of Plantain Lilies, Rush Lilies, and such like names without reference to their botanical name, then I do say that the latter are superseded, and inconvenience, to say no more, is caused. There is one passage in Mr. Burbidge's remarks which I confess I do not understand. He says: "English plant names must be used wherever English is spoken. To suppress them would suppress all trade in plant products." Does he go back from his concession as regards the joint use of scientific and popular names, and wish to represent or protest against the disuse of the former as an attempt to suppress the latter? Otherwise the first part of the passage quoted has no relevancy. And now, supposing that popular names were suppressed, with which I am not concerned, would "all trade in plant products be suppressed" also? Take the *Hellebores* as a case in point. Except Christmas Rose as a synonym for *H. niger*, I could give a nurseryman the popular name for any variety I might want; nor do I think that I should find that trade between us was suppressed in consequence. I buy large numbers of plants from various places; I have never used any but the scientific names, and I have never experienced the slightest difficulty in making known what it was which I wanted. Could I say the same if I had used solely popular names? Or, if I had done so, could I find fault with a nurseryman if I found that he had sent me a different variety or species from what I wanted?

The conclusion of the whole matter is briefly this: I contend for the use of scientific names in all cases, except when the popular name is too widely known to be unmistakable. Not to do so is to supersede the scientific name. I have no desire to suppress popular names when they are really popular. But, to quote Mr. Burbidge's words, which bring us into complete agreement, "to prevent confusion let us have Latin names also." Thus, if the *Helleborus angustifolius* which Mr. Burbidge speaks of be really distinct from all others of that kind, then it not only may, but ought to be given a distinctive varietal name; and Mr. Burbidge, as the discoverer, has clearly the right to choose the name. If the plant be not distinct (and this is really the point of controversy between him and Mr. Brockbank), then he has no claim whatever to give it a new name, much less to supersede its scientific name of *H. angustifolius* in favour of St. Brigid's Christmas Rose.

(Loughran, Co. Dublin. FREDERICK TYMONS.

A Cactus story.—The chapparal cock, which I have noticed as often being seen in Texas, is in Mexico most abundant. He is similar to a woodcock in appearance; but strange tales are told of him, and ones that I really did not believe until I heard them repeated in Mexico. That this bird lives exclusively on snakes is undoubted; but his physical powers do not enable him to assume the

aggressive towards very large reptiles. The smaller ones he picks up as sea birds do a shell fish, and, dropping them from a great height, kills and eats them. With larger snakes he has to flap his wings in their faces, dazzle them, and pick out their eyes as occasion offers. Many very large and powerful snakes, however, found in Mexico are too dangerous even for this mode of procedure on the part of the chapparal cock to be successful, and therefore he resorts to another artifice. Watching them until they slumber, he picks pieces of the huge Cactus leaves that grow everywhere there from 4 feet to 10 feet above the ground, and with these builds a wall round the slumbering serpent. Snakes of any sort will never come into contact with a Cactus: the thorns, once they get under the scales, can never be extracted; so the unlucky snake for days in rage goes round and round inside his thorny fence, and at length either dies of starvation, or, losing his reason, in frenzy bites his own tail, in which case he dies with all the symptoms of poisoning that would attend a similar misfortune to a human being. This may seem incredible to many, but it is stated in the country itself to be a well-known and not a rare occurrence.—*Field*.

FLOWER GARDEN.

SOWING AND RAISING ANNUALS.

THE time of year has again come round when most annuals should be sown, and as the several kinds require very different treatment, it may be well to make a few remarks on the more important, and to notice such as are most deserving of cultivation in order that those who would like to grow this class of plants may know which to select. First and foremost come

THE ASTERS, of which there are many varieties, the best and showiest being Truffaut's *Paony-flowered*, the blooms of which are superb. The way to raise these and other annual Asters is to sow the seeds in boxes or pans of light, finely sifted soil, consisting principally of leaf-mould, and to get them to germinate readily they should have a sheet of glass laid over the top, and the boxes or pans placed in gentle heat, when the plants will soon show themselves, and as soon as they are large enough to handle, it will be necessary to prick them off in the same kind of soil in a frame or under hand-lights from whence they can be lifted with good balls and planted out in the open. The time to do this is during a dull day, immediately after a shower, as then they do not flag, but take fresh root-hold and start off at once. To grow Asters well they must have good ground that has been deeply dug and heavily manured, so that they may get well down and find plenty of rich food to feed on. Next to Asters,

ZINNIAS are perhaps most deserving of notice, and the double kinds specially desirable, as their flowers are not only very full and well formed, but they are exceedingly brilliant, and when grown in masses, as they should be, quite dazzling, producing a striking effect. Where they do best is in sheltered positions fully exposed to the sun, where if planted in deep rich soil they will remain in full beauty till cut off and destroyed by the frost. The way to raise them is to sow in heat, and treat them in the same manner as the Asters, but as the Zinnias are much more tender, the sowings should not be effected till the end of April, nor the plants put out till the third or fourth week in May, as when raised earlier, or exposed before the season mentioned, they are almost sure to get a check, from which they are slow in recovering, and rarely do so well afterwards.

STOCKS are likewise remarkably showy, and are quite indispensable, as not only are they very brilliant and varied in colour, but they load the air with sweet odours. The best way to manage with Stocks is to sow patches or rows where they are to stand, so as to avoid transplanting, as it is a difficult matter to lift them without the plants feeling the removal, and being injured thereby on account of their having so few fibrous roots. As Stocks show bloom early it is easy to distinguish

the single from the double, and to pull the former out, thus leaving the beds full of the latter, which when together in masses make a fine show.

THE SALPIGLOSSIS is next to be commended, but as it is tender, it is useless attempting its cultivation except in favourable situations in warm soils, where, if plants of it can be so accommodated, they send up a profusion of lovely Lily-like flowers, as varied in shade and markings as they are beautiful to look on. The best way of getting the *Salpiglossis* in beds or borders is to sow thinly in small pots and plant out the first or second week in June, or to scatter seed in fine earth where the plants are to stand.

TROPEOLUMS, both the climbing and dwarf sections, help much to make a display, the first named being valuable for running up the stems of trees and clothing the bare branches or for covering fences or other unsightly objects, which they soon do, and robe them with beauty. All that is necessary is to pop the seeds in, although time is saved by getting the plants up in pots, and then planting them out in a little prepared soil to give them a start. The Tom Thumb kinds, of which there are several, make fine beds, as they are very compact, and bloom with the greatest of freedom.

PHLOX DRUMMONDI GRANDIFLORA is a choice annual, quite deserving a place in any garden where it may be used either in lines or beds, as the habit is compact and the flowers remarkably showy and fine. To grow it well light rich soil is necessary, in which it may be sown at once, or raised in pots or pans, and planted out later on in the season.

SWEET PEAS must not be forgotten, as, besides being so ornamental in the backs of borders or other positions, they are charming for cutting, a purpose for which they are specially adapted, as they work up nicely in bouquets and look well loose in vases. A neat and good way of growing them is to sow in patches and give them a few tall twiggy sticks to climb on, or make use of coarse meshed rabbit wire to run round in a circle a foot or so across, to which they will cling and hold themselves up.

GODETIAS, such as Whitneyi, The Bride, Lady Albemarle, and one or two others, are gorgeous, as they have flowers almost as large and showy as single Tulips, but more refined, as the petals are of a rich satiny hue. Being quite hardy, seed may be sown out anywhere and the plants thinned freely, so as to afford plenty of room for them to spread and grow. Like most annuals, Godetias require good soil, and the more open and deeper it is the better will they stand dry weather.

CONVOLVULUS MAURITANICUS, *C. minor*, and *C. major* are all handsome, the latter being very pretty for twining up standard Roses, and the other two for depending from rockwork or other elevated positions, where the striking deep blue of *C. minor* shows itself off to great advantage and is very effective.

NEMOPHILA INSIGNIS is also a charming annual, and one that is quite unrivalled for the richness and great wealth of its blossoms, which are put forth in such abundance as to form a sheet on the ground.

CENTAUREA CYANUS, the well-known Cornflower, is an admirable plant to grow; it should be sown in quantity for cutting, as it yields a large supply of light, elegant blooms till late in the autumn.

CHRYSANTHEMUMS Burrigeanum and Dunnetti are also very useful for the same purpose, and likewise for borders, in which they make a fine show. S. D.

Double yellow Marguerite.—Mr. Cannell is not quite correct in describing his double yellow *Chrysanthemum* alluded to in THE GARDEN (p. 326) as a variety of *segetum*. It is really one of the annual varieties, and may easily be raised from seed. It is, indeed, identical with Carter's Double Golden, a fine selection from the old annual double yellow. Its height is about 2 feet. No strain, I believe, reproduces all the flowers perfect; but, as Mr. Cannell has shown, it

can be propagated by cuttings. There is also a pure white double variety, and even though the wild *Chrysanthemum segetum* is handsome, no one seems to offer seed of it. Farmers find it a troublesome weed, while in some localities it is known under the expressive name of "Botheral." If grown in gardens, and the flowers freely cut off, the seed would hardly, I think, give much trouble.—A. D.

NOTE ON BELVOIR SPRING GARDENING.

THE following list contains the names of the greater number of the plants of which we make use at this place in spring either in beds, borders, or rockwork, viz:—

<i>Alpiea Auriculas</i>	<i>Narcissus minor & minimus</i>
<i>Anemone fulgens</i> (largely)	<i>poeticus</i> (and large collection of others)
<i>apennina</i>	<i>Omphalodes verna</i>
<i>Robinsoniana</i>	<i>v. alba</i>
<i>memorosa fl. pl.</i> (largely)	<i>Orobis vernus</i>
<i>Arabis alba</i> (an early and compact variety obtained from seed)	<i>lathyroides</i>
<i>Aubrietia aræca</i>	<i>Phlox subulata</i>
<i>grandiflora</i> (great variety from seed)	<i>frondosa</i>
<i>deltoidea variegata</i>	<i>Nelsoni</i>
<i>feeding</i> (light pink)	<i>The Bride</i> (and others)
<i>Antennaria tomentosa</i>	<i>Polygala Chamæbuxus</i>
<i>Alyssum saxatile</i>	<i>Polyanthus Golden Gem</i> and large number of fine yellow varieties from seed
<i>invulnium</i>	<i>Primula</i> (double white, yellow, and crimson)
<i>Arum italicum</i>	<i>Magenta King</i> and seedling varieties
<i>Cardamine trifolia</i>	<i>cortusoides amena</i> or <i>Sieboldi</i>
<i>rotundifolia</i> (very early)	<i>Pulmonaria azurea</i>
<i>Cheiranthus Cheiri</i> (very early dwarf yellow variety; grown largely)	<i>officinalis</i>
<i>Caltha palustris</i>	<i>Puschkinia scilloides</i>
<i>Corydalis cava nobilis</i>	<i>Ranunculus montanus</i> and <i>amplexicaulis</i>
<i>Cowslip</i> (<i>Primula macrorhiza</i> ; very early species)	<i>Sanguinaria canadensis</i>
<i>Crocus Imperati</i>	<i>Saxifraga Burseriana</i>
<i>vernus</i> and others	<i>oppositifolia</i>
<i>Daisy</i> (double red, white, crimson, and auburn-folia; largely)	<i>hypnoides</i> and a collection of the mossy species
<i>Doronicum austriacum</i>	<i>ligulata</i> (largely)
<i>Erica carnea</i>	<i>crassifolia</i>
<i>Erythronium Dens-canis</i>	<i>cordifolia</i>
<i>Epimedium pinnatum elegantissimum</i>	<i>Sedum acre aureum</i>
<i>macranthum grandiflorum</i>	<i>glaucum</i>
<i>Eranthis hyemalis</i>	<i>Lydium</i>
<i>Eritillaria</i>	<i>Scilla sibirica bifolia</i>
<i>Fumaria solida purpurea</i>	<i>Silene pendula compacta</i>
<i>Gentiana verna acaulis</i>	<i>Snowdrop</i>
<i>Galanthus Imperati nivalis</i>	<i>Stachys lanata</i>
<i>Grape Hyacinth</i> (<i>Muscari</i>)	<i>Scarlet and yellow Van Thol</i>
<i>Helleborus niger</i>	<i>Tulips</i>
<i>n. maximus atro-ruber orientalis</i>	<i>Thymus lanuginosus</i>
<i>Hyacinth</i> (large number single bedding varieties)	<i>golden and silver</i>
<i>Heuchera lucida</i> (for foliage)	<i>Tussilago fragrans</i>
<i>Hepatica triloba angulosa</i>	<i>Viola, Russian</i>
<i>Iris bicolor reticulata</i>	<i>Queen Victoria</i>
<i>Limnathes Douglasii</i>	<i>Maria Louise</i>
<i>Lunaria biensis</i> (improved high-coloured variety; raised at Belvoir)	<i>Veratrum nigrum.</i>
<i>Myosotis dissitiflora</i> (largely)	
<i>sylvatica</i>	
<i>Narcissus Pseudo-Narcissus obvallaris</i>	
<i>Empress and Emperor</i>	

Spring plants require good cultivation. There is a period in the life of a plant when it produces the best results in blossom; old, worn-out plants bloom late; ill-grown young plants produce inferior flowers. The great art is to have plants of the right age, full of vigour, and large enough to produce a good effect; then it is requisite to have clusters or masses where a single plant would be ineffective. It takes many years to secure a stock of plants, and a reserve garden is indispensable.

W. INGRAM.

Anemone apennina.—I have a white *Anemone apennina* and two shades of blue of this good plant. Every here and there comes a patch with red tinted stalk and leaves, and the flowers a deeper blue, approaching the colour of *blanda*, reminding one of the same trick of colouring in *Scilla bifolia taurica*, of which the paler blue form has green leaves and stalks, while the darker has them tinged with red.—G. J.

NARCISSUS TORTUOSUS.

I DO not wish to trouble your readers on this subject further than to direct their back again to the original note by which I introduced this purest and prettiest of all the white Daffodils to their notice (see THE GARDEN, March 24, p. 277). They will there find that Mr. Burbidge perverts what I stated to suit his present argument. He makes me (p. 362) say "having the same shortened corona and sturdy habit." Whereas I said (p. 277) "having the same shortened corolla and sturdy habit as obvallaris." This, of course, makes all the difference, and exactly agrees with Haworth's description, which he cites, viz., "Divisions of the corolla twisted, sulphur white, much shorter than the crown." Mr. Burbidge says he received from me a faded flower, and from this sole specimen he deduces that I am altogether wrong, and he proves it by misquoting (or worse) my notes. *N. tortuosus* has been in bloom here by hundreds, and has been seen by many botanists growing alongside Mr. Barr's *moschatus* and *cernuus*, and there can be no possible doubt of the difference in the three varieties, or that the *tortuosus* I have distributed exactly agrees with Haworth's description and Curtis's figure, as already fully stated in THE GARDEN.—W. BROCKBANK, *Brookhurst, Didsbury.*

—Allow me to state that after my notes on *N. tortuosus* (the Irish *N. cernuus* of Mr. Barr) were published, I discovered that I had made a slight mistake in my quotation from Mr. Brockbank's note (p. 277), by writing "corona" instead of "corolla," which latter was the portion of the flower to which Mr. Brockbank referred. I regret that this little mistake occurred, but at the same time I believe the plant referred to to be a form of *N. cernuus* rather than the true *tortuosus* of Haworth, which, according to his description, should have twisted perianth segments. As I have before said, but little credence can be given to descriptions unaccompanied by figures. All Daffodils vary so much in different soils and climates, that peculiarities characteristic in one locality are totally obliterated in another, and therefore useless for purposes of distinction. This season, for example, the orange tints on the corona of the *N. incomparabilis* variety is, I am told, far less vivid than usual. Late planting, different soils, and local influences of position, altitude, and climate cause varietal differences oftener than we are inclined to allow.—F. W. B.

Anemone nemorosa alba.—I was shown to-day a remarkable display of this *Anemone* in a garden here. It formed the edging 10 inches wide for a bed of Ghent Azaleas several yards across, between which various *Liliums* had been permanently planted. The flower is single, pendent, white, and slightly streaked with blue-purple on the back, and at least three times the size of the common white wood *Anemone*. It was most effective and discernible a long way off. Evidently peat soil suits these hardy *Anemones*, and in passing I may remark that if many of your readers planted their *Lilies* permanently as here in such a soil they might expect to find the stems now as thick as spade handles above the ground. Imported auratum bulbs are still beneath the surface with me. The *Anemones*, Azaleas, and *Lilies* make these beds effective for nine months out of the year consecutively.—W. J. M., *Clonmel.*

Triteleias.—The varieties of these are but few, the earliest being *T. uniflora*, which has been in bloom in the open borders here for the past month, large clumps of it making quite a show. We have also found it very useful for pots for the embellishment of the greenhouse, as when taken up in the autumn and kept in frames it flowers early, and is valuable for associating with *Primulas*, *Cyclamens*, and other low-growing things of that class. In taking up the bulbs for potting the largest and strongest should be selected, and when they have done blooming they may either be turned out in the border to grow on again for another year or kept in pots, but if the latter, it is necessary to continue watering them when they

require it, so as to maintain the leaves fresh till the time arrives for them to ripen and die away naturally. The soil in which *Triteleia uniflora* does best outdoors is a light sandy one, and in this the bulbs increase at a rapid rate, and the plants flower with the greatest of freedom. *T. laxa*, the finest of all the genus, is a real gem, as it sends up large many-flowered heads of bloom after the manner of the well-known *Agapanthus*, which in form and character they much resemble, but in colour they are of a rich Tyrian purple, so that altogether they are very choice, and come in admirably for cutting to furnish vases, or for working up in bouquets. At present *T. laxa* is somewhat scarce, as unfortunately it is not so free as the above-named, and is slow of increase except from seed, and plants raised in that way are some years before they are strong enough to flower.—S. D.

FERNS.

BEST CULTIVATED FERNS.

(Continued from p. 341.)

CIBOTIUM.—This small genus is composed of some half a dozen robust growing, very distinct, and highly ornamental species. The majority of them are Tree Ferns, making handsome stems, very stout in proportion to their height. The *C. Barometz* is, however, an exception to that rule, and has given rise to marvellous tales related by early Asiatic travellers, who gave it the name of Vegetable Lamb, from the fact of its having a decumbent rhizome clothed with wool like a lamb and being of spreading habit. *Cibotiums* are all of easy culture, and add greatly to the general appearance of the winter garden whenever they can be planted in it, as their magnificent fronds are all gracefully arching and light in comparison with their size. They are very accommodating as regards their food, although they prefer a mixture of two parts peat, one of loam, and one of coarse sand. When potted, those with decumbent rhizomes must be elevated a little above the rim of the pot, as they will suffer if potted too deep. They must be very well supplied with water at all times of the year, their stems being kept perfectly and uniformly moist during their growing season. In the rock fernery they should be planted on a projecting piece of rock, on which a good quantity of the above-described soil can be placed, and where they will show to great advantage. They are, moreover, a class of Ferns requiring very little or no shading at all during the summer, especially if the house in which they are kept is at all airy and lofty.

C. BAROMETZ.—This species, found in China and all over the sub-tropical parts of Asia, has somewhat triangular shaped fronds from 6 feet to 8 feet long and bipinnate, with pinnae deeply pinnatifid, closely set, and terminating in a sharp point. The stalks and rachis are more or less clothed throughout with long light brown hairs. The fronds are of a beautiful dark shiny green above, whereas their underside is of a beautiful glaucous colour. Greenhouse.

C. DREGEL.—A very handsome South African species, with beautiful drooping fronds, whose base is clothed with bright brown scales. Besides being elegantly pendulous, the fronds, which are bipinnate, are also very finely cut and of a beautiful light green colour. A striking peculiarity of this plant is noticeable in its growth, as on each frond there are a pair of small pinnae developed close to the crown, leaving a bare space of the stalk between these small pinnae (which have all the appearance of a separate growth) and the rest of the frond. Greenhouse.

C. MENZIESI.—A very handsome Fern, of erect growth, from the Sandwich Islands, and very rarely met with in collections. The fronds, produced from an upright stem, are bipinnate, with pinnae long and acuminate, and pinnules broad and obtusely lobed; the stalks, which are strong and nearly erect, are clothed all over with short, woolly-looking, dun coloured hairs. The whole of

the frond is of a beautiful dark green colour, strongly shining when perfectly matured. Stove.

C. PRINCEPS.—This truly magnificent Mexican species makes very rapidly a stout stem of good dimensions, producing numerous and beautifully arched fronds from 10 ft. to 12 ft. long, of a bright light green colour on their upper surface, while their underside is of a beautiful glaucous hue; they are tripinnate, with pinnae obtuse and pinnules slightly lobed and more rounded on the edges than in any other *Cibotium*. The stalks and the rachis, as well as the crown of the plant, are all densely covered with large light brown or white, chaffy, short hairs, feeling quite brittle when touched. Stove.

C. REGALE.—Also a Mexican species, with long, light, arching fronds, which often attain the length of 12 feet. Although more slender in all its parts, it is a more rapid grower, and forms a stem quicker than the preceding species, from which it is easily distinguished by its fronds being bipinnate and by its pinnules being long, narrow, and tapering to a point. The hairs which cover both the stalk and the crowns are also considerably longer and of quite a silky fawn colour. Stove.

C. SCHIEDEL.—Like the two preceding species, this also comes from Mexico, where it is no doubt found growing at a greater elevation, as it particularly dislikes the heat in which the other kinds thrive so well. It is a beautiful and most elegant Fern, with magnificent, robust, and yet pendulous fronds, gracefully spreading, and often measuring from 10 feet to 15 feet long, bipinnate, with lobed pinnules. It is a very free-growing kind, forming an upright stem which is said to attain in its native country a height of 15 feet, but plants with such stems must be many years old, as the formation of the trunk is a slow process in this case, and plants in cultivation with stems more than 15 inches or 18 inches are very rarely met with in any collection. This species is highly decorative, and all the more attractive, as the fronds are pale green above and very glaucous beneath; the stalks and rachis, like the crown itself, are all densely clothed with long silky hairs of a chestnut colour. The sori also add greatly to the beauty of the plant, as besides being very conspicuous they are enclosed in little caskets and situated all along the margins, contrasting strongly with the glaucous hue of the underneath part of the fronds. Greenhouse.

C. SPECTABILE.—Although this, also a Mexican species, may be said to resemble in general appearance the *C. regale*, it is readily distinguished by its much more upright habit, its narrower fronds, and by the much paler colour of the silky hairs which cover the crown and the base of the fronds, which are also of a lighter green colour than those of that species. It also stands a cooler temperature, and although growing more rapidly in the stove, it will be found to succeed very well in a greenhouse.

CYATHEA.—Some of the most beautiful of all Tree Ferns are to be found in this genus, which is very widely distributed over the surface of the globe. As regards the beauty of their foliage, they are equal in every respect to any *Cibotium*, *Alsophila*, or *Dicksonia*, while they offer a much greater variety in the sizes of their stems; those of the temperate kinds are mostly stout and nearly or quite destitute of spines, whereas most of those from tropical regions are slender in proportion to their height, and in many cases densely armed with stout spines. All the species contained in this genus are evergreen, and all of them require an abundance of water at the roots as well as their trunks being kept constantly moist. By these means and by them only can these beautiful plants be induced to make fine heads of fronds which will last all the longer on the plant if they have gradually been inured to the sun during the summer. The soil they require is the same as that given for the *Cibotium*, viz., two parts of fibrous peat, one of loam, and one of silver sand as coarse as possible. They are all of very easy culture, and, provided the moisture about the

stems is well attended to, there is very little fear of failure in their cultivation.

C. ACULEATA.—This West Indian species makes a handsome, tall, and somewhat slender stem, surmounted by a very fine tuft of bi or tripinnatifid fronds growing from 6 feet to 8 feet long; they are of a dark green colour, and their stalks are completely covered with short spines. This plant also possesses the peculiarity of developing a pair of small pinnae near the base, giving it a very strange appearance. Stove.

C. CANALICULATA.—A very handsome Fern from the Mauritius, making stems of a very dark colour, and growing to 10 feet or 12 feet high. The fronds are bipinnate and very leathery, from 4 feet to about 5 feet in length, and of a dark shining colour above and paler below; their stalks are densely covered with long black chaffy scales. Stove.

C. DEALBATA.—A very beautiful kind, and deservedly the most popular species of the whole genus, having handsome fronds from 10 feet to 12 feet long, produced in great abundance from a stout stem; they are pinnatifid, of a fine shining dark green on their upper surface, and of a beautiful silvery white underneath, from which it derives its name of Silver Tree Fern. When planted in a conservatory in a rather elevated position it makes a very grand object, and shows itself to perfection when seen by artificial light. Greenhouse.

C. HORRIDA.—This very curious and beautiful Tree Fern from the West Indies is rarely seen in cultivation, probably on account of the difficulties met with as regards its importation, which is rendered more difficult by the slender constitution of its stem. It is a most interesting species; the stalks are thickly covered with light brown pubescence, through which large brown-black thorns protrude. These thorns, which are also to be found on the underside of the rachis and as far as the very terminal points of the pinnae, often measure a quarter of an inch in length. The fronds are of a very dark green. Stove.

C. MEDULLARIS.—A magnificent species from New Zealand, which cannot be mistaken, as no other Tree Fern bears the slightest resemblance to it. It is the most gigantic of all its genus, and produces in its native country a stem upwards of 40 feet in height, bearing magnificent spreading fronds from 12 feet to 15 feet long and proportionately broad, borne on robust stalks, first of a prune colour, but which become with age of a jet black hue and beautifully polished; before the young fronds are fully unfolded they are densely covered with long, black, chaffy scales. It is of most rapid growth, and if planted in a conservatory where plenty of room can be allowed for its perfect development it makes a good-sized stem in a very short time, and is by far the most imposing of all Tree Ferns which will succeed well in a greenhouse.

C. SINUATA.—This rare little Tree Fern from Ceylon is very elegant in all its parts, as it forms a stem of very slender dimensions, the thickness of which very often does not exceed that of an ordinary walking-stick. The fronds, which are produced in great quantities, are simple, entire, and pointed; they are from 12 inches to 15 inches long, and about 1 inch in breadth, with prettily undulated margins. They are of a light shining green, and of a thin texture, with beautiful venation. Stove.

C. SMITHII.—A very handsome species from New Zealand, with stems 10 feet to 15 feet high, bearing a great quantity of beautiful feathery bi or tripinnate fronds 5 feet to 7 feet long. They are finely cut, indeed more than any other *Cyathea*, with pinnae 8 inches to 12 inches long, and of a bright green colour. The crown, as well as the stalks on their whole length, are covered with long, chestnut-coloured chaffy scales. It is highly decorative on account of its graceful and light fronds, but does not bear the action of the sun so well as other species of the same genus.

ELLERA.

GARDEN FLORA.

PLATE CCCLXXXVI.

PHILESIA BUXIFOLIA.*

THIS beautiful plant, of which the accompanying plate is a good representation, has attracted some attention of late, both on account of its ornamental character and its hardiness—at least in the warmer parts of this country and Ireland. Although a near ally of *Lapageria*, and possessing attractions almost if not quite equal to those of that plant, whether judged from the point of beauty or from the ease with which it may be cultivated, yet while the one has become in every sense a popular garden plant, the other, until within the last two years, has been comparatively unknown, notwithstanding that its introduction dates back some thirty years or more. Messrs. Veitch, to whom we are indebted for the introduction of the *Lapageria* and hosts of other fine plants, also introduced the *Philesia*. It proved to be hardy in their nursery at Exeter in 1853, flowering out of doors, and it was from these out-of-door grown plants that the specimens exhibited in London in the year just named were obtained. Messrs. Veitch have made good use of this plant and the *Lapageria* by crossing them, the result being a hybrid named *Philageria Veitchi*. This plant, interesting from its being the progeny of two distinct genera, whose characters it combines in an intermediate manner, is not yet sufficiently known to enable one to speak as to its usefulness in a gardening point of view, but if the general rule that hybrids flower more freely than true species holds good in this case, we may look forward to the *Philageria* proving itself a valuable addition to our cultivated plants.

Reverting to the *Philesia*, it may be interesting to note that the finest specimens of which we have any record were grown in Cork in tubs, one on each side of a doorway. These specimens were 4 feet in diameter and produced hundreds of flowers every year. A glance at the annexed plate will give some idea of the beauty of such specimens. It flowers freely out of doors at Glasnevin, and also in the south of England. Even in Edinburgh, where the winters are often severe, Mr. J. Anderson-Henry has had a plant of it that has grown and flowered for some years on his rockery without any protection. North of the Thames in England there appears to be no instance of its growing out of doors, possibly because it has never been tried.

CULTURE.—Like the *Lapageria*, the *Philesia* requires plenty of water always and protection from bright sunshine. Peat soil with a good sprinkling of sand is a mixture it prefers. For pot culture or for planting out in a conservatory or cool pit this plant will prove most serviceable. At Kew in the winter garden there is a fairly good specimen of it growing on a small rockery under the shade of Tree Ferns and in the company of the allied *Callixene* and *Luzuriaga*, where it has been for some years and seems quite at home. In pots it is found to be a good practice to grow it in a cool, shady house or pit till autumn, when it should be placed out of doors in a shady situation. Thus the wood gets well ripened and a good crop of flowers is ensured. A mixture of peat, charcoal, and sand suits it well when grown in pots, giving plenty of pot room, and disturbing it at the root as little as possible; in short, the treatment under

* Our sketch was made in Messrs. Veitch & Sons' nursery, Chelsea, last autumn.

which *Lapagerias* thrive is the right treatment for the *Philesia*. It may be propagated by division, or, if a quantity be wanted, it may be layered, as is done in the case of the *Lapageria*. *Lapageria*, *Philesia*, and *Philageria* have been successfully propagated as follows: A young ripened shoot is selected and pegged down on a pot filled, or nearly so, with sandy peat, twisting the shoot round and round until it is wholly within the rim of the pot. About half an inch of soil is put over this, and the pot is then placed in a warm house under a hand-light or a bell-glass. The eyes commence to push in about two months or so, and when large enough are severed from the parent shoot, each being furnished with a little tuft of roots. The *Philesia* may, however, be increased by means of cuttings in the ordinary way, as it strikes more freely than either of the others. Hand-glass protection during severe frosts might be resorted to with advantage in the case of plants growing out of doors. B.

SEASONABLE WORK.

FLOWER GARDEN.

DRACÆNAS.—Most of the varieties of *Dracæna* are so tender as to be only suited for indoor decoration, but there are a few so hardy as to render them all but indispensable for open-air use in the summer flower garden. The kinds to which we allude are *D. australis*, which has broad, bright green foliage; *lineata*, a sort with narrow green foliage; *gracilis*, a kind with very narrow striped green and brown foliage; and *Veitchii*, a species much like *australis*, but stiffer in the foliage, and, therefore, better able to withstand the force of the wind. For sub-tropical bedding arrangements these *Dracænas* are invaluable, and a very few plants serve for a large bed, as, owing to the recurved and drooping habit of some and the spiral and perfectly round form of others, in order to show them off to the best advantage, it is necessary to give them plenty of space, nine or twelve good plants being ample to furnish a bed 12 feet in diameter. Thus planted, and the ground beneath them carpeted either with *Sedum acre elegans* or Golden Thyme, no more beautiful sub-tropical effect could be desired. They also make capital lawn plants, and in warm, sheltered positions stand our average winters. Several large plants of them stood out here for years, but they all succumbed to the severe weather experienced in 1880 and 1881. They may be propagated at any season from seeds or cuttings. Ours are obtained by cutting up the old stems and corm-like roots into pieces of about 1 inch long; these are placed in pans of sandy soil just in the way in which Vines are propagated, and plunged in a brisk bottom-heat, in which they quickly form roots and break into growth.

SUMMER BEDDING ARRANGEMENTS.—These at the present time demand all but a monopoly of attention as regards propagation, arrangement, and planting. Winter effect having to be considered as well as summer, in order to avoid much autumnal removal, every hardy plant anything like suitable is pressed into the service; this to some extent excludes as unsuitable many plants which we should otherwise like to use, and in some degree robs the summer garden of its gaiety, but this loss is more than repaid by the extended season during which it is effective. Space will not admit of giving in detail all the arrangements now being made from the standpoint just alluded to, but the following treatment of a large circular bed may be taken as a fair example of the many ways in which hardy and tender bedders may be planted in combination: It is edged with *Herniaria glabra*, green, and the groundwork, or divisional lines, which cut up the bed into smaller circular or oblong beds, consist of *Veronica incana*, greyish white, the smaller angles being filled with *Ajuga reptans purpurea*, and the central and smaller beds as follows: In the centre

is a large plant of *Phormium tenax variegatum*, which is quite hardy here; this is surrounded by *Viola Blue Bell* and *Ageratum Cupid* in mixture. The oblong beds have for the centre small plants of *Cupressus erecta viridis*, and a surrounding line next the *Veronica* of *Coleus*, the centre being filled in with tricolor *Pelargonium Sophia Dumaresque*. The small circles have as centres small plants of *Retinospora pisifera aurea*; one half of them is filled with *Lobelias* of the pumila section, and the other half with *Alternantheras*. It will thus be seen that the whole of the framework of the bed, including the centre, is entirely composed of hardy plants, and therefore its conversion to a winter bed is an easy matter. Some of our beds have more, and others a less number of hardy plants than that here given, so that the bed just described may be accepted as about the average. When determining these arrangements and selecting plants for them, our preponderating thoughts are length of season during which the plants continue effective, the reducing of labour by propagation of tender kinds, and the saving of house room for other and more profitable purposes. Most of the plants which we use have from time to time been alluded to; among those now being planted are *Sedum glaucum*, *corsicum*, and *acre elegans*, *Saxifraga rosularis* and *oppositifolia major*, *Cerastium arvense* and *tomentosum*, *Echeverias*, *Sempervivums*, *Lamium maculatum aureum*, Gold and Silver Thymes, *Gnaphalium lanatum*, *Helichrysum plicatum*, *Veronica incana* and *rupestris*, small shrubs, *Yuccas*, *Chamaepeuces* (Fish-bone Thistles), *Violas*, and *Calceolarias*.

PROPAGATING.

AROIDS.—Most Aroids are easily propagated; the climbing kinds, such as *Philodendrons*, *Monstera*s, &c., pushing forth aerial roots in great profusion, need but a suitable spot in which to establish themselves, and, in the case of others, division may be practised successfully. With *Caladiums* another method is followed, by which numbers may be obtained from but few plants. When they start in spring, as soon as the first leaf is developed, shake them out of their pots and remove the soil. This done, if the corm is large, several shoots will be growing therefrom, and just at the base of each shoot several young roots will be pushing forth. In that case, take a sharp knife and remove each shoot with its adhering fibres. In this way every one will form a young plant, which must be potted in a small pot and kept close till the roots start, when they may be inured to the air, and grown on as rapidly as possible during the summer in order to get established by winter. After the young growths have been removed pot the corms as before, when another crop of shoots will soon be produced, which may be treated as just mentioned. In this way great numbers are produced every season. With two or three kinds of *Amorphophallus* we were somewhat puzzled, for, with the exception of an offset now and then, we could not increase them, and the smooth, regular shaped root-stock rendered it doubtful if they could be increased in the same way as *Caladiums*. We found, however, on trial that they could. Care was taken to have the centre shoot well rooted before removing it, when numbers of young shoots were in most cases produced from different parts of the old root.

INDOOR PLANTS.

ALLAMANDAS.—When these have made very long straggling growth without showing flowers they may have their points nipped out; the shoots should then be trained regularly over the trellis, bringing the points low down. This will cause a quantity of the black eyes to break that in due time will show bloom. See that the plants are now liberally supplied weekly with manure water,

BOUGAINVILLEA GLABRA.—Keep the strongest shoots, which are those that must be depended on for flowering, in an erect position, as if allowed to droop they break back, which interferes with the blooming. Of all the hard-wooded stove

plants that we have ever grown, this under pot culture, if allowed to get anything approaching dry at the root, has its blooming the most interfered with. If it gets a check in this way before the bloom is formed, the shoots usually do not extend further, but set a few flowers at the points in place of the long wreaths that are forthcoming when all goes well with the plant. Both this and *Allamandas* will stand manure water in a stronger state than most things, and to have them in the vigorous condition essential to profuse flowering, they must have it, as has been stated, weekly after the roots and top growth have begun to move freely.

PLANTS IN SMALL POTS.—For the purposes of ordinary cultivation it is a great mistake to use larger pots than can be made to suffice either for flowering plants or for those that are grown for their effective foliage. In the case of the former, where too much root-room is allowed, it induces over-extension of the shoots and foliage, and often a straggling condition collectively without proportionate increase in the quantity of flowers. Where larger pots are used for fine-leaved subjects than needful, their appearance is neither so attractive, nor are they so enduring, as gross, over-luxuriant foliage soon loses its bright, healthy look. In addition to these objections, where plants are so treated as to induce extraordinary development, there is necessarily less room for variety; consequently in the potting operations that take place with the stock generally through the spring months it is well to give no more root-space than is requisite, trusting to the aid of surface manuring or liquid stimulants to keep the plants in a robust, healthy state. This particularly applies to such plants as are wholly or partially shaken out, and which have their soil renewed annually. Where plants are wanted for exhibition purposes, and size is an object, to some extent, this course may be departed from, especially when grown in thoroughly light-giving structures and kept close to the roof, conditions which directly check over-extension of the top growth. In the case of soft-wooded plants of quick growth a continuous supply of manure water at short intervals is indispensable at this season, and it must never be given too strong. For quick-growing plants like shrubby or herbaceous *Calceolarias*, *Cinerarias*, *Fuchsias*, *Pelargoniums*, *Hydrangeas*, *Petunias*, and tender annuals we have found no better plan when once the pots get thoroughly full of roots and the flowers formed than to use it continuously every time the soil requires moistening until the blooming is over. Hard-wooded greenhouse plants, such as *Azaleas*, *Aphelexis*, *Boronia*s, *Acacias*, *Chorozemas*, *Correas*, *Daphnes*, *Myrtles*, *Eriostemons*, *Pimeleas*, *Polygalas*, *Pleromas*, *Neriums*, *Hoveas*, and *Genistas*, at this season of the year when taxed with the development of their flowers or with shoot growth are greatly benefited either by manure water or the use of some solid fertiliser applied to the surface of the soil, which will not only assist the current season's bloom, but its effects will be still more apparent on the ensuing growth.

SEEDLING PRIMULAS AND CINERARIAS.—Those who have really good strains of these useful plants, and who are desirous of saving seed which they can rely on, should select in the case of *Cinerarias* plants that possess the best form and colour of flower. Each plant possessing these properties should be isolated from the inferior stock whilst in bloom, as in this way only can seed that will produce flowers of the requisite stamp be secured. As regards *Primulas*, the later sowings made last year which have not been so much weakened by blooming as the earliest will be in the best state to seed freely; these should be set on a shelf or stage under the influence of strong light and sufficiently supplied with water, nipping out the successional flowers formed after enough for seed purposes have been secured.

ROSES.—Tea Roses in pots that have been forced and flowering for some time will, if strong, yet keep on making wood that will yield flowers, but to have them of large size and sufficient in quantity the plants must be regularly and liberally fed with rich surface dressings. Where

any falling off occurs in this matter, the after-growth will come too weak to flower; or if a portion of it does bloom, the produce will be thin and poor. It rarely happens that pot Tea Roses in the hands of private growers yield nearly the quantity of flowers of which they are capable through want of liberal feeding. The nature of these Roses is to keep on all but continuously growing when in a temperature that admits of such taking place, but unless they receive a regular and liberal supply of manure in either a solid or liquid form, they neither increase in size nor produce flowers in abundance. They require and will bear much more in the way of stimulants than is generally supposed, and so applied they have a much better effect than any quantity of solid matter added to the soil which they will bear at the time of potting. Where the plants are turned out in beds, and their roots have thus unrestricted space in which to extend, they naturally are better able to take care of themselves, but even in this case a free use of manure water will be found advantageous. Whether cultivated in pots or planted out, they should be regularly syringed every day to keep down red spider, not merely sprinkled in the way often thought sufficient, but letting them have water without stint, so as to drench the foliage. Where Rose culture under glass is ever expected to be above mediocrity, there must be a ceaseless outlook for mildew, especially during this and the ensuing month, and wherever a curled leaf is seen sulphur should at once be applied.

FRUIT.

PINES.—The weather being generally bright, early-started Queens, now swelling rapidly, will take more generous food than can be given in dull, wet seasons. Keep the soil in a healthy growing state by the use of clarified liquid and guano water, and damp all available spaces after closing, which should be pretty early, so as to insure a high temperature from the afternoon sun with a corresponding degree of atmospheric moisture; but guard against much overhead syringing, as it encourages the growth of crowns and suckers, at all times prejudicial to the full development of the fruit. Endeavour to keep the bottom-heat steady at 90°, ventilate early when strong firing is needed to maintain a night temperature of 70°, gradually increase the air until about 1 p.m., and close in time for the afternoon sun to raise it to 90° or 95°. If any winter starters remain on hand give them the above treatment until they begin to colour, and then remove them to a dry, warm place to ripen. Examine the roots of plants intended for starting early in June, and, while guarding against injury from drought, induce a period of rest by withholding water for a short time and keep them moderately cool, particularly through the night.

SUCCESSIONS.—Where strong bottom-heat is obtained from fermenting materials, spring-potted plants soon fill their pots with roots and require shifting on. To carry on the system of keeping small batches in advance of each other always have materials of all kinds dry and ready for use at any time, and never on any account shift a plant into a larger pot unless its roots are in a moist state, as no amount of after-watering will ever penetrate a hard, dry ball when it becomes embedded in the rough turfy soil adapted to its future growth. Keep all young stock near the glass, shade from very bright sunshine, and give plenty of air to prevent them from becoming drawn into weakly growth.

ORCHARD HOUSES.—When the stoning process is complete make the final thinning, bearing in mind that a light crop of fine fruit gives more satisfaction than a heavy one. Always give the preference to Peaches and Nectarines which point to the sun or can be coaxed into doing so, otherwise the stalk instead of the apex will receive the colour so much admired, but not always attained. A general pinching of all the strong shoots will now be beneficial to the rapidly swelling fruit, but weak ones will be best left alone, as the only wood

bud which they make is at the point, and stopping would render the shoot useless for another year. Good syringing and liberal feeding must have daily attention, and sharper forcing may be indulged in by day, particularly when the house can be closed with plenty of solar heat and moisture, but hard forcing is not advised, as it invariably ends in pale watery apologies for Peaches which nobody thinks of eating. It is understood that the house must be closed every afternoon for the attainment of size, but night air should be given, and the temperature should range from 56° to 58° at banking time, and 50° in the morning, with a steady rise to 65° or 70° by day.

LATE HOUSES.—If the trees in late houses were clean and in good condition, the "set" of fruit will be all that can be desired, as the days have been brilliant, and although the nights have been cold, we have seldom had occasion to light a fire. With such hopeful prospects, lose no time in giving relief by timely thinning down to within a moderate percentage of the intended crop. Disbud by degrees, use water freely, always warm if attainable; feed with weak liquid manure for the present, and aim at a firm, sturdy growth by giving plenty of air through the early part of the day, and by closing in time for the water from the last syringing to dry off the foliage before night-fall. If fires are available, be ever on the watch, as a severe frost might injure the young fruit where blossoms would escape. Where Plums or Cherries are grown with the Peaches, they will do best in the coolest and most airy part of the house, as a close, moist atmosphere often does more mischief than dry frost. Figs require the warmest end, and Pears, where space is limited, may be plunged on a warm border out-of-doors when the fruit begins to swell and there is no longer danger from spring frosts. Look well to pot Strawberries on the side shelves, and keep them well fed and syringed, as it is to their culture that we are invariably indebted for the first appearance of spider.

CHERRIES.—As soon as the stoning process is complete and the fruit shows signs of colouring discontinue wetting the trees with the syringe, and maintain a free circulation of air to prevent condensation or the presence of stagnant moisture, otherwise a large percentage of the finest fruit will crack and become useless either for present use or for hanging on the trees for a considerable time after it is ripe. If very early ripening is an object, a little more warmth may be given through the day in preference to making any alteration through the night, but unless this is really necessary the same steady mode of culture which has been hitherto followed will give the best result. Examine the borders and if sufficiently wet to finish the fruit mulch with some dry, non-conducting material to keep in moisture; but if, on the other hand, they are likely to require another supply, choose a fine bright morning for giving the needful quantity at the mean temperature of the house. See that the trees are quite free from aphids, as smoking cannot be resorted to when the fruit is in daily use. Tie down leaders, stop side shoots to form spurs, and see that strong-growing late kinds which are expected to hang are regularly and evenly clothed with foliage without being in any way crowded. Follow the usual routine in late houses, always bearing in mind that a low night temperature and an abundance of air by day are the first elements of success. Give the trees plenty of water, and syringe regularly up to the time of colouring. Keep grubs in check by picking and smoke for green fly.

MELONS.—Early Melons now swelling fast will require liberal feeding with warm liquid until they have attained their full size and show signs of changing for ripening, when a moderate quantity of pure water to prevent flagginess will keep them going and improve their flavour. If the plants are well cropped, lateral growths will no longer be troublesome, and as the size and quality of the fruit will depend upon the health of the old foliage, this must be kept clean and free from insects by copious syringing every afternoon at closing time. Morning syringing in light, bright houses must now be given up, otherwise the foliage will scald;

but all paths, walls, and surfaces may be well damped with warm water as soon as the morning heat begins to rise. Ventilate early to allow moisture to dry off the foliage, then gradually raise the heat to 85° or 90° with sun; close at these figures, and descend to 70° for the night. Grow on successions with plenty of heat, air, and water, but carefully avoid producing a gross habit by feeding until after the fruit is set and swelling. Keep the glass clean, never shade after the plants get established, thin out and train the young growths, also remove male blossoms, and allow a wild, abandoned style of growth during the time the fruit is setting. The end of this month is a good time to make up manure beds in the frame ground for the growth of a summer crop of Melons, and as a steady heat is of the greatest importance, let the manure and leaves be well worked and fermented before they are put together. Build the bed just large enough to receive the frame, make it very firm, and protect from the weather. When the heat begins to decline and approaches 90°, prepare the hills in the usual way, always bearing in mind that the strong roots should be prevented from going down into the manure by the use of large sods of fresh turf laid Grass-side downwards along the centre of the bed. To economise compost and to facilitate feeding, place two broad planks on their edges and 2 feet apart longitudinally on the sods; fill loosely with compost, beat firmly when warmed through, and turn out the young plants 12 inches apart.

KITCHEN GARDEN.

VEGETABLE MARROWS, ridge Cucumbers, and Gherkins—all useful vegetables—should just now claim attention. We make trenches 8 feet wide and 1 foot deep, building up the soil at the edges of the trench and filling it up with old material used for Seakale and Rhubarb forcing in the spring. Mixing with this a few loads of fresh manure from the stable soon gives the whole mass a nice gentle heat. We then earth it over from each side of the trench, and it is ready for hand-lights placed in the centre. We always sow the seed about the first week in May, taking the nurserymen's advice to sow thickly and thin early. Early Potatoes now showing above ground should be earthed over to keep them safe from frost; when caught and blackened they never turn out so good a crop. The frost seems to paralyse and does them much injury. Turnips, Spinach, Parsley, Brussels Sprouts, and a pinch of Cabbage seed may now be sown, the Brussels Sprouts being for late use, but all spring Broccoli keep in the seed store until the beginning of May. Beet should now be sown; also make successional sowings of Peas. Broad Beans should be sown according to the demand. Witloof sow at once if wanted, but that now is very rarely. The ground lately occupied with Broccoli should now be made ready for Celery by taking out the trenches. Lettuces may be planted on the ridges. Well manure the trenches and dig them up a good depth if the soil admits of it, and by the time the plants are ready the soil will be well pulverised through the action of the weather. Mustard and Cress, Radishes, &c., sow in accordance with the demand.

FORCING GROUND.—The present backward spring has proved the importance of cold pits, frames, and hand-glasses for bringing forward a good supply of early succulent salads and vegetables. At the present time they will be full of Potatoes, Carrots, Turnips, crisp Lettuces, and a host of spring-sown plants of Cauliflower, including Veitch's Autumn Giant and Dickson's Eclipse, two of the best varieties in cultivation, Brussels Sprouts, and Cos Lettuce. The great point in the management of these inexpensive structures is ventilation through the early part of the day to secure stout, stocky growth, followed by early closing with solar heat on fine afternoons. The drying winds and bright sun will have prevented full exposure of the tender plants, but a healthy growing atmosphere may be maintained by tilting the lights on the south side. See that Potatoes and Carrots are copiously supplied with tepid

water, choosing the early part of the day, as it is important that the foliage becomes dry before night. In the warmest section look well to Tomatoes, Capsicums, Vegetable Marrows, and Cucumbers intended for planting on ridges of half-exhausted manure from the Seakale and Rhubarb. Pot on the plants as they require it, and guard against having them drawn by keeping too close through the early part of the day. French Beans enjoy plenty of heat and moisture in a pit which can be well ventilated on the ground line to prevent a stagnant atmosphere. Make successional sowings in pots or otherwise for preceding the first crop in the open air, which will be late this season. A good batch sown in small pots for planting in frames after Potatoes or on early borders where they can have temporary protection will do good service. A good Mushroom bed should be made up in a dry shed facing the north. Almost any kind of short fermenting manure with an admixture of turf will do for the body of the bed, and this may be faced with horse droppings and stiff loam for the reception of the spawn.

HERBS.—In many pretentious gardens herb beds are very often neglected or left to take care of themselves, the same subjects being allowed to occupy the same spot from year to year until eventually they die out and disappear. A warm convenient corner is generally selected, and being strong, exhaustive growers, such things as Mint, Tarragon, Sorrel, Camomile, and Pennyroyal should be broken up and replanted either on fresh ground or with a good addition of new soil annually. We sometimes hear gardeners say Tarragon positively refuses to grow and live through a winter, but if replanted in fresh soil every spring and allowed to carry all its old stems until new growth starts, this useful herb, like many hollow-stemmed, herbaceous flowering plants, will pass unharmed through the wettest winters. Just now the old flower-stems on our bed are 3 feet high, and young growths like quills will soon be ready for use. Chervil also likes change, and in order to allow it to accommodate itself we hang a few seed-bearing stems about in pyramidal fruit trees, and always find an abundance of healthy plants. Thyme, one of the most useful herbs grown, very often falls off before the end of a severe winter, but if sown annually and planted out in new stony soil at the foot of a west wall it will thrive and set the first of most winters at defiance. It is the constant cropping and picking which injures Thyme, and to avoid this the young plants should have a year's grace before they are interfered with.

KITCHEN GARDEN.

POTATO PLANTING—LARGE V. SMALL SETS.

THERE has been much dispute at times on the subject of planting large *versus* small sets of Potatoes. The late Mr. Robert Thompson, of Chiswick, gives the theory of the matter in his "Gardener's Assistant" thus: "In all plants large buds tend to produce large shoots, and small or weak buds the reverse. Now, the eyes of Potatoes are true buds, and in small tubers they are comparatively weak; they consequently produce weak shoots, and the crop from such is inferior to that obtained from plants originating from large tubers furnished with stronger eyes." One is surprised at a statement like this coming from such a practical man as Mr. Thompson, but perhaps all that is written in his name is not his. Still, many gardeners yet adhere to the idea that large sets produce the best crops, which *but for bud* is not by any means true, and as planting is conducted at present, viz., by planting a certain distance between the sets and between the rows, be the sets large or small, nothing is gained by planting sets of extra size. I always plant sets whole if they are small, and if they are large I cut them, being convinced, as I am, that the small sets are as good as the large ones. It is quite a fallacy to suppose that small Potatoes comparatively produce the weakest buds. The true theory

of the matter is this, as anyone may see for himself. Large Potatoes produce the greatest number of eyes, and consequently the most buds, but the buds are not stronger than those on smaller tubers, for the reason that in both cases the number of buds is always in proportion to the size of the tuber, and, therefore, the buds on a large tuber have no greater reserve of vigour behind them than those on the smaller tuber. This is my experience, at least. I have examined hundreds of tubers, and have found that, while a moderately large tuber will have twelve or fourteen or more eyes or buds, a smaller tuber will not have above half that number. The two sets should, therefore, be equal, and it is so, for the buds on the one are just as strong as those on the other. As the rule in planting is to plant all the sets the same distance asunder, and disbud to one or two buds at the crown, it follows that the cropping power of the two tubers must just be about the same. I freely grant, however, that the biggest Potatoes—that is, the Potatoes with the most buds—produce the heaviest crops, for the more stems the more tubers, but these stems must have proportionately more room; hence, those who believe in this theory do either give their large sets more room and save all the eyes, or else they cut the large tubers into two or three sets and plant them separately as we do here and as plenty of others do. The size of the sets is not a matter of so much importance, perhaps, in gentlemen's gardens, but it is to farmers and cottagers whose supply of seed is taken out of their general food store. I attach much importance to the simple fact, proved over and over again, that a large Potato cut into three good sets produces twice or three times the weight of crop that a large set divested of the greater portion of its buds does, and also more than a large Potato planted whole with all its buds, but not allowed proportionate room. The whole subject of cut and small *versus* whole and large sets wants enquiring into further than it has been.

J. S. W.

WINTER BROCCOLI.

A GOOD supply of winter Broccoli is invaluable where there is a large demand for good vegetables, and there is no more useful variety than Snow's Winter White, which comes in in November, and if the weather continues mild its season lasts more than six weeks. Osborn's Winter White makes a good successional crop, following, as it does, closely after Snow's, but wholly distinct from it. It is not only more vigorous in growth, but produces larger heads. Both these sorts require to be treated in the same way. They should be sown any time during April, but the earlier in that month the better. A piece of ground should be set apart for that purpose. Our winter Broccoli and Brussels Sprouts I like planted on ground that was occupied the year previous with Carrots or Parsnips. It is necessary to plant in well-manured deeply-dug soil, which ought to be prepared during winter and allowed to remain uncropped. Plant 2 feet apart each way, and dull showery weather should if possible be selected for the operation; at the same time there must not be any serious delay in getting the plants out; first, because they will be getting crowded in the seed bed, and secondly because they should be got out as soon as they are large enough for transplanting, so as to give them as long a time as possible to make their growth, for as they come into use in November, under the most favourable circumstances the time in which they have to make their growth is not too long to get strength sufficient to produce good-sized heads. In dry weather we always draw drills about 3 inches deep, in which to plant them, and then, if they require water afterwards, the drill prevents any waste, as it concentrates the supply where it is likely to reach the roots; the only after-attention they require is to keep them free from weeds, and the surface moved occasionally between the plants with a Dutch hoe. In November, if there is any appearance of frost, it is a good plan to go over the plantation every week, and as fast as heads fit for table are formed dig up the plants, shake all the soil from their

roots, and plant them again in a bed of soil in a cold pit or frame, taking care that they are not too much crowded. Under such circumstances it is an easy matter to protect them, and they keep just as well as if they were left in the open quarters, even if the weather should be mild.

J. C. C.

GARDEN EDGINGS.

ALL live or plant edgings are to be preferred on the score of picturesqueness; all dead edgings on the score of endurance and utility. In choosing between live or dead substances it is well to determine fully at the first whether the after cost and labour of maintaining live or plant edgings will be recompensed by their greater irregular beauty and freshness, or whether it is best to face the first cost of some hard material, and having properly laid it be assured that the first cost was about the only one. I think we may take it for granted that ninety-nine gardeners out of every hundred would prefer a solid, hard edging to their kitchen garden paths in preference to edgings of plants of any kind. If a live edging of any sort is to be put down, the general verdict will be in favour of Box, because that of all hardy plants is the most fitted and most enduring. Box needs trimming only about once in the year; and if done in the spring and neatly, very little further trouble is given. Still, to have a good edging of Box it is needful to lift, thin out, and replant every few years, for an edging 6 inches in height and as much through, and which gets thin below, and broken, and irregular in many places is not a tidy or desirable edging, and cannot be recommended. Now, a thick margin of Box becomes a fine cover for snails and slugs, and very frequent hand-weeding is needed to keep it free from Grass and other obnoxious plants, so that even so popular an edging plant as Box is not without its objections, especially in those gardens, and they are many, where labour is short. Perhaps no kind of labour is less remunerative than is that expended upon the maintenance of path edgings. All plant edgings are liable to become preservers of weeds, and need constant overhauling to keep them down. No greater nuisance can exist in any well-kept garden than a weed preserve close to the gravel paths, for weeds should never be permitted to seed upon the gravel. Again, many plants are recommended as edgings that bloom freely, as, for instance, the small and large Thrifts, Violets, Daisies, Cerastiums. However pretty as edgings plants may look when in bloom, they are simply detestable when the flowers are decaying. The giant Thrift, for instance, with its big heads of bloom borne on stems 10 inches high, would, with the first shower, be found sprawling all over the path, and very unsatisfactory that would look, and indeed, as I know to my cost, does look. Then in the winter the birds, and especially big birds, have a peculiar penchant for plant edgings, and seem to find them full of insects, for they literally tear them to pieces and cast the portions all over the paths. This is peculiarly the case with Aubrietias, Daisies, Sedums, and similar dwarf creeping plants. As to the question of labour in keeping plant edgings in decent order, I have found the most satisfactory results from the use of *Festuca viridis*, one of the dark wire Grasses; for although the plants bloom in the spring, yet once this is clipped off there is an end of work, so far as the plants are concerned. Moreover, until in some half-dozen years after planting the edgings have become too dense, they not only want no farther attention, but give a graceful outline, as the Grass is dwarf and free in growth. Violets, especially strong growing kinds, are most unfit for garden edgings. Few would think of recommending them; fewer still would think of using them. Without doubt the best of all dead edgings are those made of stout plain tiles or of specially made bricks. I prefer hard white bricks made 12 inches in length, 2½ inches broad at the base, and bevelled in on one side only—the path side, to a rounded top edge of 1½ inches. These should be set evenly upon a hard base surfaced with sand, and have the ends tied together or set with cement to exclude

weeds from the joints, and keep the line straight and even. Such an edging as this would, if set well, with ordinary care endure for 50 years, and thus prove of life-long usefulness and service.

A. D.

NOTES ON BIRDS

In the Garden, Sheen Lodge, Richmond Park.
(Continued from p. 350.)

SPARROW (*Passer domesticus*).—Our colony remains pretty stationary as to numbers; they are never molested, and are fed in winter. Being formerly accustomed to coax these town birds at that season to the windows of my official residence in Lincoln's Inn Fields, I was hardly prepared to do justice to the well-marked, agreeable, un-sooted attire which both sexes, and especially the males, present in the clear atmosphere of my present abode.

BULLFINCH (*Loxia pyrrhula*).—This visitor is readily recognised by its well-marked, varied, glossy plumage. Though the native notes be simple and not loud, the vocal organs are susceptible of being trained to discourse motives, and even to emit intelligible words. One would not suspect from the native note of this fine-plumaged bird that such vocal accomplishments were hidden through lack of tuition. But the success of the German trainers of its powers of song is testified by the prices given for accomplished pupils, and especially for the pair of cock bullfinches who have been taught to sing in parts.

CHAFFINCH (*Fringilla cælebs*).—This lively, pretty bird announces its early arrival by notes which soon, growing in power and regularity of recurrence, might be construed as an instance of natural musical rhythm. The species change their quarters according to the season, but without any distant migration.

GREENFINCH (*Fringilla chloris*).—My only recorded notice is of its active, varied flittings about the shrubberies during the pairing season in April.

LINNET (*Fringilla linaria*).—To this well-known bird I am indebted for its occasional sojourn in winter-time, as well as for the ornament which the bright red breast of its nuptial plumage in April and May adds to the transient gleams of colour amongst the greenery in the spring season. Its lively, sweetly varied song is then also a welcome addition to the feathered orchestra.

GREATER REDPOLE (*Fringilla cannabina*).—In its spring plumage this may be easily mistaken for the linnet, but its instinct of nidification is different and is constant. I have never found its nest in a bush—always on the ground, generally concealed by the Ground Ivy which carpets the shrubberies.

GOLDFINCH (*Fringilla carduelis*).—This charming bird, tempted by the abundance of larval food at its nursery time, occasionally looks in from its favourite nesting places—the Thistles, Gorse, and Teazels of the adjoining preserve and neighbouring commons. But our contiguous "palewell" has been invaded by the early bird-catcher from the Seven Dials, and the Gorse bushes there have concealed no nest of goldfinches during the latter periods of my explorations.

STARLING (*Sturnus vulgaris*).—These active gregarious birds inhabit and breed in vast numbers in the trees in and near Coombe Wood, but I am always favoured with their visits to the lawns, which they help to clear of worms, myriapods, and insect larvæ. Save an occasional raid on the Raspberry bushes, I have nothing to lay to their charge, but I have been the recipient of groans from accomplished "growers" on the score of their wholesale depredations.

JAY (*Corvus glandarius*).—I was one summer shocked at the spectacle of three fine specimens of this beautiful bird shot by my gardener and laid out for laudatory inspection near the Pea rows in the kitchen garden. At the season when the luxury of fresh-gathered Peas is a welcome feature of the dinner-table it is aggravating to your grower, who has taken all due pains and care in the supply, to see the havoc which these greedy plunderers make in the well-laden rows. "They comes, sir, out of the preserve a'most as fast as I

can shoot them, and wouldn't leave a cod on the stem if they had their own way; they care nothing about your old hat and coat there, sir, on the stick." "Well, Collins," I replied, "we must see what we can devise in the way of a more effectual 'scare.'" I got some balls of twine and white worsted; I set the maids in the evening to knot portions 2 feet in length of the worsted to the twine at intervals of about 2 feet. A length of the twine so arrayed was stretched over each row of Peas, and with every movement, however slight, of the air the worsted tags were in perpetual agitation. I have not since heard any complaint of a visitation from my beautiful feathered neighbours of the adjoining wood. I have listened with pleasure to their cheery, loud, and varied notes, but cannot make up my mind to pay for them with fresh, ripe Peas.

CARRION CROW (*Corvus corone*).—This is one of the park birds under the ban of the ranger; but it is significant of their craft and wariness that I have never found a pair absent there, with their nest well hidden in some generally grand old Oak. How the species comes to be reckoned among my garden visitors is this: At early dawn and sunrise in June and July, if we have succeeded in getting a brood of bonny ducklings, which then have the "run" of a part of the front lawn temporarily wired off, a pair of carrion crows steal quietly into the covert of the old over-shadowing Chestnut tree, then in flower or full leaf. Choosing their moment, they swoop down, and each bears away a duckling in its beak. A warning that such was the cause of diminution of the brood led me to leave my bed at daybreak, and with the gardener watched, concealed, this manoeuvre; but I could not give the word to "shoot." I thought it well worth the loss for once, but afterwards I covered the brood plot with netting, which has proved an effectual check, though the predatory visit is often repeated as this season. From the

ROOK (*Corvus frugilegus*) I have received nothing but favours. They take their share in diminishing lawn pests and other insect plagues; their ways and instincts afford endless interest. When I took up my abode at Sheen Lodge, there was in the Elm wood leading there from Sheen gate a small rookery at our end. I am bound to say that at the nesting season complaints of being awoken and kept awake, from 3 a.m., were frequent and well founded; but this is the only exception to the pleasure which the cawings at evening and other reasonable times have given to one whose busy life, in great proportion, is spent in London.

My friend, the author of "Recreations in Natural History," especially enjoyed his visits at the rooks' breeding season, and the worthy magistrate declared that he should unquestionably commit certain members of the cawing community for theft and burglary if they had been other than feathered bipeds. The case was this. A young married couple could always be discriminated by the unusual activity displayed in preparing the abode for the incubator and her coming brood, yet, by reason of the unconscionable practice of their elders, and possibly parents, they spent twice the time and trouble in completing the nest than did the more experienced birds or than was fairly needful.

The old couple, perched near the framework of their former nest on a higher branch, instead of flying forth to collect their own lining materials, awaited the return of the younger pair, each with a beakful of moss or wool, which they then busied themselves in properly disposing in their unlined nest. This being done, forthwith off they flew again to gather more material, whereupon the stationary old rooks, who had generally monopolised the topmost localities, would hop down from twig to twig and deliberately transfer the lining material of the young pair's nest to their own; nor, until the old birds had thus provided for themselves, were the young couple permitted to finish theirs.

We sometimes fancied we saw movements of the plundered ones, after fruitless flights, indicative of suspicions of foul play. But, in the long run,

all went on well; the coming generation was duly hatched out and provided for. Food could not be larcenously fetched from the beaks of the new-wedded ones' brood so easily as the wool from their nests.

In the seventh year of my residence the rookery was broken up; the birds changed their locality, not without satisfaction expressed by the female powers at the lodge. The circumstances were these. Some aged decaying trees in the Elm wood were condemned, but the forest authority had postponed their removal until the time when the rooks were confined to the duties of incubation. The noise and row of laying bare the roots and prostrating the trees, crashing past their neighbours in their fall, may be conceived. The whole colony, male and female, rose in the air, wheeling wildly about, and cawing loudest emulous imprecations at the radical procedure. But not one of the Elms in which they had built was touched. In two days all was cleared away and peace restored.

Broderip watched with me the commotion, and we speculated whether the females would return to their nesting duties. They did so; brought out and reared their broods as usual. A remoter speculation with both of us was as to the effect of the scare on future proceedings. Nothing occurred in the course of that year to indicate a change of rookery affairs; but the rooks did not return to their nests the following spring, nor have they ever returned. The nests have gradually rotted off or been blown away, and all sign of the old rookery has departed.

Applying one's own—of course, highly superior—psychical powers to the predicament, one feels disposed to say that the birds, or the older and more experienced members of the community, came to the conclusion that the disturbance in spring was a revolutionary procedure; that no constancy of the conditions of a respectable rookery could be trusted any longer in such a locality; therefore, "we had better be off and settle elsewhere," which they did, and the community thrives peacefully to this day in a wooded part of the park about half a mile off. Whether it was a matter of debate submitted to the November parliament of rooks, which assemble in numbers, blackening acres of the park sward on the other side of the piece of water in front of my abode, I presume not to surmise, but our keepers hold the belief that rook felonies are judged of at such gatherings, and point to some unlucky or worn-out ones usually left dead on the ground as convicted individuals that have been dealt with accordingly. It is, at all events, an interesting period of the year to the observant naturalist.

On calm, misty days in November, in soft weather, when the ground yields easily to the grub-extracting beak and the crop is well filled, the rooks will assemble as if for sport, then sweep through the air in curving flights with unwonted swiftness, and as they near the ground wheel about and turn over like tumbler pigeons, not resting long on the ground when alighted, but flying up to the lower branches of the nearest Oak or Elm, as if waiting for later arrivals to the "caucus." The rushing and sweeping noise they make as they swoop in this playful flight is remarkable; the accompanying modified cawing comes then nearest to a song.

Leaning motionless against the trunk of one of the tall Elms near my abode to watch this sport, I have been made aware of the accession of fresh families to the assemblage by the "sough" or rushing sound in the air before I caught sight of the birds, which from their lofty flight swept suddenly down to join the general association. Meanwhile, the air resounds with clear modulations of shrill and singular notes like those of the daw combined with the hoarser croaks of the rook. As they settle down the sward of the park is speckled for acres with at first ever-moving black spots, which are finally aggregated in a dense multitude. In an hour or so the assembled *Corvidæ* disperse.

THE JACKDAW (*Corvus monedula*) may contribute its quota, but it is indistinguishable when

not forming part of a looser flying flock. The nest of this species is, in my locality, usually concealed in the hole or hollow of some old Oak, in and out of which the parents may be seen busily passing during the month of April.

MAGPIE (*Corvus pica*). — The rare, but occasional, visits to the garden of this active, prying bird are looked upon with suspicion, but I cannot charge it with any abstraction from the poultry yard or the toilet-table, the window of which may be temptingly open in summer mornings and evenings.

The penchant of both pie and daw for glittering objects, utterly useless, as it seems, to them, never suggested any explanation to my mind till I saw the "bower" which my friend Gould brought home, with his accumulated ornithological treasures of

like nest is impracticable. But it might have been enjoyed in prehistoric times, and some lingering trace of the ancestral bower-building and bower-adorning instinct may be at the root of that otherwise inexplicable penchant to abstract and fly off with a bright object which the bird cannot, at the present advanced state of post-glacial Europe, put to any manner of use. We have no evidence at least of a daw or magpie laying the filched silver spoon or jewelled ring at the feet of his bride.

RICHARD OWEN.

PUBLIC GARDENS.

HULL BOTANIC GARDEN.

A GENERAL meeting of the shareholders of the

it would have a botanic garden; and if it did not want one it would be useless to attempt to force such an institution upon it. To enable them to determine this question Dr. Rollit said he should again put facts and figures as plainly as possible before them, and he then stated that the Company owed about £26,000, viz., a sum which might, it was believed, be compromised for £20,000. This was in respect of the balance of about £22,000 or £24,000 due as the purchase money of the gardens to the North-Eastern Railway Company. There were also owing other debts, obligations to make roads, interest, and the like, about £6000. So much for the capital account, which showed about £26,000 to be owing. As to revenue, this depended on the number of subscribers. The appeal for subscriptions, which had been issued, had produced

Nephrodium Rodigasianum, a new plant shown at Ghent (see p. 387).

specimens and facts, from Australia. In one of these singular constructions, now in the British Museum, by a species akin to our *Corvidæ*, both entry and exit of the "run," formed by the long Australian Grasses, carefully stuck down in two opposite rows and interarched above, are ornamented by collections of coloured shells, gay feathers, and other bright objects, for example, quartz pebbles, including, in one instance observed by Gould, a glittering line of gold. The building of the bower is mainly the work of the male bird, and, as Gould observed, the added treasures might be collected as an attraction of the female by a parade of wealth; the construction is wholly distinct from the nest. The courting couple chase each other in successive runs through the bower. The female then selects her tree and in a secluded part of the branches builds a nest resembling that of the magpie, and there she rears her brood.

It is evident that the preliminary structure on bare ground could only be made and enjoyed in an extensive uninhabited or sparsely populated country. As our Australian colonists spread, the *Chlamyderæ* must go farther afield to indulge in their courting and dancing bowers. In a land like ours such a structure preceding the business-

Hull Botanic Garden Company was held on the 18th inst. to take into consideration—first, the continuance of the gardens after the present season; second, the suggested transfer of the gardens to the Corporation; and third, the winding up of the Company or otherwise. Dr. Rollit, the recently-elected chairman of the Company, presided. The secretary read the minutes of the previous meeting, at which it was resolved that the North-Eastern Railway Company should be allowed to retake possession of the gardens at an early date, and in the meantime the Corporation be approached with a view to the gardens being secured to the town either as a park or as botanic gardens. The chairman said the fact was, that by the last meeting public opinion had been aroused by means of plain speaking, and the shareholders and town had now begun to realise that, unless they acted at once to some purpose, the botanic gardens would be lost to both. The directors and himself were most anxious that it should be otherwise, and that, for the sake both of science and public recreation, the gardens should be kept open in some form. But little or nothing could really be done without the co-operation of the shareholders and the public, and, in short, if the town wanted a botanic garden

some result, and some of the directors and the curator had already obtained many additional subscriptions, facts which perhaps justified the strong opinion of the curator that amply sufficient subscriptions could be obtained to meet current expenses, and even to leave a surplus. The practical problem was, therefore, how to raise the £26,000 due on capital account, or at least £20,000, which must be paid to the North-Eastern Railway Company in October, since that Company was bringing an action to recover possession of the land, and time had only been granted until the date he mentioned. The great difficulty had been from the first, and was still, that the gardens had been weighed down by surplus building land.

The suggestion of the Board was that that land should be divided into plots, each having a frontage to the gardens. There would be ninety-six such plots, but if only eighty-six were sold it would raise a sufficient sum to pay the railway company. If, therefore, they were taken up the gardens might be saved; if not, they would be lost. There was, however, one alternative which the resolution of the last meeting had directed to be investigated. It was to inquire whether, if the Company was unable to survive, the Corpo-

ration would be willing to take and maintain the garden as a public park. With this object he had seen the Mayor and the Parks Committee, and he thought he might say that the suggestion was one which might be entertained, and that it would be legally practicable to maintain the gardens in much their present condition as a place of public recreation and as headquarters for stocking and storing plants for the public parks of the town. Nothing had, however, been determined. The directors were anxious to do everything in their power to maintain the gardens if they met with practical encouragement, and there were reasonable prospects of ultimate financial success.

Mr. MacMahon, the secretary, in reply to Dr. Gibson as to what the cost of keeping the gardens up, supposing all the plots were sold, said he had estimated the total expenditure at £1200 as against an income of £1550, leaving a balance of £350.

Mr. Copland thought it would be a lamentable thing to see a fine property on which £15,000 had been expended banded back to the North-Eastern Railway Company, or even handed to the Corporation, although he should prefer that the Corporation should take the gardens rather than the railway company. He did not think that it would be a serious effort on the part of many gentlemen present to take plots of land.

Colonel Pudsey was strongly in favour of the gardens being continued. The motion was then put, with the following addition: "That the Board be and are hereby directed and authorised to keep the gardens open for the present session; that all possible subscriptions be solicited and obtained at once, and arrangements for fêtes, flower shows, and the like be forthwith made." The motion was carried unanimously. It is satisfactory to add that of the eighty-six plots required to be taken to pay the railway company, fifty-two were bespoken, thus leaving only thirty-four to be disposed of. When this is effected, Mr. MacMahon is of opinion that the gardens are likely to be placed on a firmer and more satisfactory basis than ever they have hitherto been.

GARDEN DESTROYERS.

REMEDIES FOR INSECTS.

ON Roses or Peach trees, if aphides are very troublesome, it is a good plan to use tobacco water, with which the trees may either be syringed or the shoots dipped in it. The way in which to prepare the tobacco water is to steep tobacco in it, a pound being sufficient to make four gallons quite strong enough to kill any aphids. Tobacco juice is offered for sale, but I do not find it any better or cheaper than that which one can make. There are many insecticides, however, that are good, one of the safest and best being nicotine soap, which is fatal to aphides without doing harm to the foliage. Where many Roses, Peaches, and Cherries are grown and much insecticide is required, a strong steep may be made by using Quassia chips, which may either be boiled or soaked in hot water, the former being best. With the Quassia some soft soap should be used, as well as tobacco, the proportions being a pound of the former and half a pound each of the latter to 12 gallons of water. When strained, this liquor may be applied with a syringe, and if used at a temperature of 90° or 100° it will do its work well.

Next to aphides, the worst insect with which we have to contend is the Rose maggot, a grub which folds itself up in the leaves, and in some knowing way brings them in contact with the flower buds, which it eats out or destroys. Insecticides do not reach this pest effectually: the only method of getting at it is either to pick it out or smash it *in situ*; the latter is the most expeditious plan. A similar kind of grub often affects Apricots, and may be searched out and dealt with in the same way; but the maggot to be found on Apples and Pears must either be picked off or knocked down by means of a forcible washing by the garden engine. The Gooseberry caterpillar is another

plague, against which various remedies have been recommended, one of the most effectual being Hellebore powder, and another almost equally good is the liquor in which Foxglove leaves have been boiled, applied by means of a syringe. Lime water also destroys it, but it should be used clear, so as to leave no deposit on the Gooseberries; and as prevention is said to be better than cure, it is a good plan to scatter lime under the bushes in the autumn, which destroys the grub in the ground before it can hatch.

Red spider, though most minute, is a pernicious insect, as when it gets on Peaches and Nectarines it gives them an impoverished look by sucking the sap out of the leaves. The primary cause of red spider is poverty, brought on either through dryness at the root or over-cropping. The remedy, therefore, suggests itself, viz., thinning out the fruit sufficiently and watering. Before this latter is done, however, the ground immediately around the trees should be mulched with half-rotten manure, which keeps the earth uniformly cool and moist, as when water is given it can soak in, but without the manure it quickly evaporates. What red spider dislikes very much is being wetted, and, that being so, its quarters may be made most uncomfortable by means of a garden engine or syringe, a shower bath of this kind being also most refreshing to the foliage after a hot summer's day. S. D.

Killing mice (p. 345).—The following are two good recipes for killing mice and rats. I have used both and find them to be good: First recipe—125 grammes crumbs of bread, 60 grammes of butter, 30 grammes nitrate of mercury crystallised, all well mixed together in an impalpable paste; lay some of the mixture on pieces of glass in the house where the mice are. Second recipe—250 grammes quicklime (not slaked) in powder, 50 grammes sugar in powder, 150 grammes flour of any kind (oat, wheat, or rye); mix well together, put some of the mixture on a little plate, and place near it a second plate with water. Mice after eating some of the mixture feel thirsty and drink the water. The lime, being quick, gets slaked in their stomachs and kills them in a few minutes.—A. B., *Bourg-la-Reine*.

— IN THE GARDEN of the 14th April is a paragraph on killing mice, in which it is stated that Battle's Vermin-killer contains arsenic. From my examination, Battle's Vermin-killer contains strychnia, not arsenic. A threepenny packet contains about one grain of strychnia, with wheat, starch, and Prussian blue. If the mice eat Battle's Vermin-killer they will be soon destroyed, and by strychnia, not arsenic.—ANNIE H., *Lincoln*.

AN ITALIAN MARKET.

AT some distance from the West End Hotel, the Hotel de Londres, and other pretentious buildings which compose the modern San Remo, you turn down a small street leading from the principal one where the best shops are to be found, and you arrive at a picturesque square, the Piazza del Mercato.

The old houses and shops which enclose it on two sides are curious, while it is bounded on the east by the ancient cathedral of San Siro, with its Romanesque nave and its gaudy Renaissance west front, its tall campanile and its not unmusical bell, the remaining side consisting of a sort of verandah, affording protection to stalls, at which various useful and ornamental articles are sold. Here stands an itinerant mender of glass and china. His booth is just now crowded with anxious matrons or careless maidens bearing broken dishes, plates, or basins for his inspection. It is to be hoped that he performs his cures at a low rate, as the articles appear to be but of trifling value. Beside him lies a heap of papers of the wonderful cement, and he is now, with many gesticulations, explaining its virtues to a handsome, but weatherbeaten *contadina*, who decides to purchase six packets.

As the crowd disperses I observe him (he is a good-looking fellow, in brown jacket and waist-

coat, with an orange neckerchief loosely knotted round his sunburnt throat) carefully eyeing himself and arranging his curly hair before a morsel of looking-glass produced from his waistcoat pocket. He has done a good stroke of business to-day. Further on you pass through an archway, over which is inscribed "*Lavorio pubblico*." You descend a short flight of steps and look down on thirty or forty laundresses of all ages, from the wrinkled grandame, whose grey locks are appropriately covered with a bright red or yellow handkerchief, to the young girl with the large silver earrings and cross, and her dark hair coquettishly arranged. All are hard at work, washing their clothes in a huge tank or stone basin 40 feet or 50 feet long and about 12 feet wide. What a clatter! Their tongues go faster than their hands and arms, but these are not idle. How they scrub and wring! While peals of laughter resound through the stone arches which support the building. From the antiquity of these and from the Gothic windows, I conclude this may be the ruined crypt of a church. It is quite open on one side, and the bright Italian sun lights up their handsome faces. They are evidently charmed with their own jokes, or it may be (as they look up from time to time) that they are making fun of the idle Englishman, who is himself amused at the stirring scene. But it is of the market that I would chiefly speak. If you wish to buy provisions here you should not be later than 9 a.m., by which hour many of the careful housekeepers are making their purchases. This is considered one of the best markets on the coast, hardly excepting those of Cannes or Nice. Here you can procure every kind of fish caught in the Mediterranean, game in the season (I never can quite make out what the proper season is here, as partridges were offered us last Sunday at the *table d'hôte*), fowls, turkeys, guinea fowls, butter, and eggs. But the pride of the market is not in these. The show of fruits and vegetables, for the time of the year, was one of the best I ever saw. Apples, Pears, Oranges, and giant Lemons plucked with their leaves; large bunches of Celery, Cardoons, and Fennel, the roots of which are boiled here and eaten like Seakale; small red Carrots freshly gathered, bunches of excellent Asparagus, hampers of green Peas, crisp Lettuces, Potatoes without stint, but greatly inferior to those of English growth; Leeks and Onions, big Orange Gourds, some round, some long; Spinach and bouquets of fragrant herbs; while from the top of the stalls depend long ropes of Shallots and Garlic, enough of the latter to flavour all the dishes in the peninsula; dried fruit, Plums, Figs, and Raisins, with Almonds. There were no flowers, but these may have been disposed of earlier in the day, or may have found their way to the shops in the fashionable part of the town. The market itself is very picturesque. In the middle stands a fountain, always surrounded by merry girls filling their bright copper vessels, and enjoying a little gossip at the same time, while two tall Plane trees cast the shadow of their yet leafless branches across the square. Though the piazza is crowded, everyone is sober, notwithstanding there are no less than five shops where *vini nostrali e diversi* (native wines and others) stand ready to be drawn in huge casks. Look at that dark-haired peasant as he stops his curious open cart, drawn by a handsome mule, whose somewhat complicated harness is adorned by a number of red tassels. He is about to drive a bargain with that sunburnt old woman who is selling *conserva de tomates* (a dark red preparation heaped up in a pancheon, and not over-inviting either in taste or smell) at two soldi a measure. Life seems to be a joke to that peasant. There is a ring in his musical voice as he declaims in his Ligurian *patois*. His slouched hat, with its small feather, shades a face which an artist would love to paint. How rich the colours with which a southern sun has stained it. His fine, well-built figure seems well adapted for his free and simple life amid the mountains which border the Mediterranean. I have always thought the Italians of this district a noble race. They are thrifty and industrious, hardy and independent. They do not beg, and are

kind and courteous to strangers. Nature, in giving them for an abode an earthly Paradise, has endowed them in addition with some of her best gifts of body and mind.

MARK NESFIELD.

NOTES FROM THE GHENT SHOW.

IN addition to the report which we gave last week of the international show at Ghent, we find, on turning over our notes, the following, which may be of interest to our readers. With regard to new plants, usually the most interesting feature of an exhibition, we append a few notes respecting some of those which appeared to be worthy of special comment. Among the

NEW FINE-FOLIAGED PLANTS we omitted to mention last week the remarkably fine group which was exhibited (not for competition) by the Compagnie Continentale d'Horticulture, managed by the well-known horticulturist, M. Linden. This group contained some two dozen plants, all of which were new and many strikingly beautiful. One of the most distinct was *Aglaonema pictum*, a handsome leaved Aroid recently introduced from Sumatra. It has broad ovate leaves of a rich glaucous green blotched and marbled with silvery markings exactly as in the accompanying illustration, which represents the plant about a quarter its natural size. It is a handsome plant for pot culture in stoves, and being very neat in growth and not inclined to become "leggy," makes it particularly valuable as an ornamental plant. Another beautiful new plant shown by M. Linden, who has given us the opportunity of illustrating it, is *Nephrodium Rodigasianum*, a native of the Samoa Islands. It is a most elegant stove Fern, and one, moreover, of easy culture. The long pinnate fronds gracefully arch on all sides of the plant, and being of a lively green have a very pretty effect. *Vriesia bellula*, an attractive plant of the Bromeliad family, was shown in flower. It has a vasiform tuft of foliage and a flower-spike bearing scarlet and yellow bracts, the two making it very pretty. *Alocasia Putzeysi*, which is much in the way of *A. Thibautiana*, and quite as handsome, is a plant that will find favour as a fine foliaged plant, as the colours of its large heart-shaped foliage, which hangs vertically on all sides of the plant, give it such a rich and telling effect in a group. For its noble leaves, reminding one of *Theophrasta*, the new *Wormia Burbidgei* will be a welcome plant, and it has the desirable property of producing its huge foliage when the plant is still small; its flowers are said to be pretty. Two handsome species of *Schismatoglottis* were shown by M. Linden. These were *S. Lavallei* and *Lansbergi*, the latter an uncommonly pretty one, with deep green velvety leaves on bright red petioles. *Becheveria decora* may be best described as a variety of *E. metallica*, with the leaves marbled and streaked with white instead of being wholly of a livid purple. *Heliconia triumphans* is a Maranta-like plant with oblong leaves of a bright emerald green, blotched and barred with a deeper hue. Other plants shown by M. Linden were *Dieffenbachia magnifica*, *Begonia Diadema*, *Zamia myriophylla*, *Pothos aurea*, *Aralia gemma*, an extremely elegant plant; *A. reginae*, and *Massangea hieroglyphica*: the last we considered one of the most remarkable plants in the whole show; it was a gigantic specimen, with leaves some 4 feet or 5 feet long, deeply channelled and transversely marked with irregular stripes on a pale green ground. The foliage spread out in an elegant recurved vasiform tuft, rendering the plant a beautiful object as regards form.

NEW PALMS.—Collectively, the Palms, though numerous, were not at all very remarkable; undoubtedly the most valuable new plant in the whole exhibition was the true *Pritchardia grandis*, a Bornean Palm, only recently introduced in quantity by Messrs. Veitch. It is an extremely handsome plant with broad rounded leaves, spreading out in a noble tuft on all sides. The blade of the leaf is folded into singular angular ridges, as if it were plaited, and the upper

surface is somewhat convex, which adds much to its stately appearance. The reason it is called the true *Pritchardia grandis* is on account of there being another Palm in commerce under the same name, but which turns out not to be the true plant, but a *Licuala*, and therefore now called *L. grandis*. It is distinct from *P. grandis*, and also a noble and handsome Palm, having broad plaited leaves, but more wedge shaped at the base than in *P. grandis* and not so spreading or stately. There is ample room in gardens for both these fine Palms, and in order to praise one, there is no need to speak derogatorily of the other. The plants of *P. grandis* shown on the present occasion were all comparatively small, the largest leaves being only about 12 inches or 15 inches broad, miniatures in fact of the fully developed leaves. The colour of the whole plant is a bright grass-green, which, together with its noble port, renders it distinct from any other Palm in cultivation. This plant was shown by two or three exhibitors in their collections of new plants, but singularly enough it was not shown in the class for the best new Palm, otherwise it would certainly have been first, as the Palm shown for the highest award in that class was very remarkable. It was named *Pritchardia Vuylstekiana*; it had broad, slightly recurved foliage, but the whole plant had the appearance of being in the juvenile stage. The second best new Palm was also shown by M. Vuylsteke, who exhibited the *Pritchardia*. It was called *Sagus amicum*, and had pinnate leaves, though not half so graceful as many other older kinds on the same table. A Californian form of *Washingtonia filifera* called *W. robusta* was considered to be the third best. It is considered to be more robust and harder than *P. filifera*. It came from M. Van Houtte. There was a class for ten new Palms, but not one of the plants shown in the several collections struck me as being very remarkable, excepting *Pritchardia grandis*. The names of the others were *Arenga Moensi*, *Wallichia Moensi*, *Ravania Hildebrandtii*, *Kentia costata*, *Pinanga* (sp.), and a variegated *Chamærops humilis*. This collection was shown by M. Moens, who appears to be a specialist in Palms, judging by the numbers he exhibited and many other fine examples. Another ten from M. Vervae and Co. consisted of *Pritchardia aurea* and *P. grandis*, *Kentia Luciana*, a very handsome Palm; *K. gracilis*, *Ptychosperma Seemannii*, *Calamus australis* and *viminialis*, and the much-heard-of *Bismarckia nobilis*, which, however, in its present infantile stage is not in the least extraordinary, but it may develop into a noble Palm. In the third ten were *Pritchardia glauca*, *Calamus Tringany*, similar, if not identical with *Dæmonorops fissus*; and *C. pataniensis* in the way of *D. paleobanicus*. *Veitchia Johannis*, in the same collection, was a graceful Palm; likewise *Chamædorea tenella*, but much like an older and well-known species. We might here add a passing word in admiration of the Palms shown in the classes, about eight in number, specimen plants, which formed such a remarkable feature of the show. The gigantic plants from M. Ghellinck de Walle and M. Moens, who took the principal prizes amongst amateurs, and M. Van Houtte, M. Spaë, M. de Haene, M. M. Vervae, the leading prize winners in the nurserymen's classes, were really grand, and showed plainly to what an extent and also to what perfection Palms are cultivated in Belgium.

NEW INDIAN AZALEAS.—Considering how numerous are the varieties of Indian Azalea, which may even be counted by the hundred, and how beautiful the best are, one would have thought that raisers of new sorts had long ago reached the climax of perfection. Such is not the case, however, with some of the Ghent nurserymen, who seem indefatigable in the matter of Azalea raising, and every year numbers of novelties come from their hands to compete with, and maybe supersede older kinds. On this occasion it seemed as if there had been an accumulation of novelties for some seasons, so numerous were they. As the Azalea constitutes such an important element in the Ghent exhibitions, there were eighteen prizes set apart for new varieties appar-

tioned to six classes, and the total number of plants shown was no fewer than seventy, the majority of which were superior to older sorts. The principal exhibitor was M. Louis Van Houtte, from whom a great number of the finest Azaleas have emanated. In five of the classes for new sorts this exhibitor took the first prize, and in some he won the whole of the prizes offered. The finest collections of six new sorts included the following, all semi-double, namely, Baron Nathaniel de Rothschild, with very large flowers of a bright purplish violet, one of the finest; Comte de Paris, salmon-pink; Comtesse Zebrowska, a fine semi-double white; Charles C. Brigham, brilliant crimson-scarlet, flower large and of perfect shape; John Hawkesworth, large double flowers of a rich salmon-pink; Remembrance of Princess Alice, brilliant rosy carmine, large and beautiful; Mdme. Van Wassenhove, full double pink, with white margin and spotted with crimson; Sakuntala, one of the best whites shown; Marshal P. Wilder, large, white flaked with pink; Prince Rudolphe, bright Indian red, very beautiful; Mdme. J. E. Planchon, white flaked and striped with rose; and Comte Adrien de Germigny, a brilliant crimson-cerise, large and fine. Among the plants in the two collections of four plants were *Souvenir de Arthur Veitch*, white flaked with rose; Mrs. Harry Veitch and Mrs. B. S. Williams, both very fine whites; and Remembrance of Princess Alice, already alluded to; T. W. Moore, a good carmine; Princess Beatrice, pure white; and these, together with one called John T. D. Llewellyn, a sort with double salmon pink and white flowers, and which won the highest medal constituted the pick of M. Van Houtte's varieties, and all of them will no doubt find their way into English gardens, and supplant older sorts of smaller colours. The finest of the whole lot we thought was Baron N. Rothschild, a kind very distinct from any other both as regards colour and other points. It is noteworthy, too, that all, or at least the majority, of M. Van Van Houtte's seedlings were semi-double, which some will consider a doubtful innovation. For our part we prefer either the decidedly single or a good double, not intermediate. Another prominent exhibitor of new seedling Azaleas was M. Vervae, who showed some really beautiful varieties, for the most part pure singles. His plants, however, were all small, and did not make such a display as M. Van Houtte's, but some of the varieties he showed were unsurpassed. The finest from this exhibitor were *La Tendresse*, a lovely sort with very large single flowers of snowy whiteness; M. Labrousse, semi-double, a kind of carmine-crimson and very brilliant; *Honneur de Gand*, very large, single, crimson-cerise; Edmond Vervae, in the way of the well-known variety *grandis*; Mad. Hermann Seidel, a semi-double white, one of the finest; *Perfection de Gand*, rosy crimson, very large; *Colomba*, white striped pink; and Mdme. Louise Vervae, a fine double white. Of all these the two named *La Tendresse* and M. Labrousse attracted us most, and both will undoubtedly have a bright future.

NEW RHODODENDRONS.—As we remarked last week, *Rhododendrons* were shown admirably by two or three exhibitors, and one collection of standard specimens in particular was as fine as one could see at any London show. The varieties, too, were of the best; but we observed that the majority of them were of English raising, and particularly the fine varieties that have been sent out from the Surrey nurseries of the Waterers. There was one class for eight new varieties, but on the whole the collections shown were not remarkable; one or two, however, we thought worthy of note, being uncommonly fine. The finest of all was one shown by M. Louis Van Houtte, under the name of Marie Van Houtte. It has dense massive trusses with large open flowers with crisped edges, white faintly shaded with pink. This was the admiration of everyone, as it stood out so conspicuously from all the rest. Another fine one shown by M. Van Houtte was called Mad. Wilhelmine Van Houtte; it had a dense truss and flat open blooms of a delicate rose-pink, shaded with white and spotted with yellow. One, George de St. Gervois was a beautiful pink, but lacked other

good qualities, and there was nothing remarkable about any of the rest. Among the other varieties of Rhododendrons shown was one in M. Vuylsteke's collection in the way of Joseph Whitworth. It was, as regards size and form of the flower, finer than any we have hitherto seen; it measured fully 4 inches across, and was perfectly flat; the colour was a rich plum-purple. It is the kind of flower that we want more of in our own varieties, but taken on the whole, and judging by the material at this exhibition, we have nothing to fear as yet in the matter of hardy Rhododendron raising. It was interesting to note that fully two-thirds of all the Rhododendrons in the show, which numbered some scores of varieties, were of English raising.

this plan; indeed, none whatever is wasted, except that carried through the chimney. We doubt, however, if the practice would find much favour in this country, for few gardeners would care to have such a scorching hot corner in their houses, and the risk of poisonous fumes is great. In this same house, which was a sharp pitched span designed for a fruit tree house, we noted that the flow was carried along the base of the roof while the return was carried along the front of a narrow border raised about 4 feet above the path. The ventilating apparatus in one house we thought excellent. The house was a long span-roofed one, and the top ventilators were so arranged as to open simultaneously throughout the whole length of the house by a lever at one end.

devices for quick working. In some there were thin transverse diaphragms; in others the plates ran longitudinally, and we imagine every one of them would be capital workers and very durable, for they were all well made, being of wrought iron and strongly rivetted. Another exhibitor had a series of copper boilers in various patterns, horizontal, vertical, plain, and tubular. One of the tubular copper boilers was in action at the exhibition, and it did its work very quickly and efficiently in every way. Of all boilers these are no doubt the quickest in action, but whether they are as durable as iron, or whether they repay the higher cost, is questionable. Probably some of our readers could give an opinion on this matter. There were numerous other garden

Aglaonema pictum, a new plant shown at Ghent.

PLANT HOUSES, though not numerous shown, possessed a few points of interest. One, a spacious span-roofed structure, was heated entirely by gas, which was ignited in a small copper furnace placed outside the house, and the heat from which was carried round the house through three 2-inch pipes placed immediately beneath the stages, which were formed of thick burnt clay tiles resting on crossstrips of T iron. Special care was taken so that no fumes from the gas could escape to the interior of the house, but whether the practice would answer in a lengthy trial was not apparent, neither could we clearly see what the heating capability of the system was, as the sun was powerfully playing on the house throughout the whole week. In another house we observed that the whole of the heating apparatus, including the boiler itself, was inside the house. The boiler was an ordinary saddle, fed from the outside, but so constructed that no fumes from the fire could reach the interior of the house. There is no doubt that a deal of heat is economised by

Simultaneous opening of ventilators is a common contrivance in our houses, but this one was different from any we had previously seen, but a sketch is needed to illustrate exactly what the plan is. There were several iron houses, and one we observed was contrived so that it could be readily removed in sections, which, bolted together, form a neat span-roofed house. We saw no style of glazing save the old-fashioned putty glazing, which, after all, is perhaps as good as any. The houses exhibited by Messrs. Foster & Pearson, of Beeston, Notts, for which two gold medals were awarded, were of their well-known stamp—one a plant house, the other a fruit house, and both perfection as regards the workmanship, fittings, and quality. Their frames, too, with their patent fastenings seemed to attract a deal of attention, being something unusual in Belgium. There was a goodly number of boilers exhibited, some of which were quite out of the ordinary run of boilers made here. Most of them were modified saddles, that is saddle shape with various

appliances, implements, &c., exhibited. Lawn mowers were miserably represented, and, judging by the display, there is not much demand for them. Those shown were little more than toys, so different from the powerful machines exhibited in this country. If the display was weak in lawn mowers, it was strong in pumps, for we have rarely seen so many of such diverse patterns, and, judging by the show of them, we should say that the Belgians are a long way ahead of us in the matter of garden water engines and pumps. There were rotary pumps of all descriptions, and all of them seemed to have been constructed on the newest principle, and always with due regard to easiness of working, a great point in a garden where labour-saving is an object. We saw a boy working one of the largest rotary pumps and throwing out such a large volume of water as from a pump of the old-fashioned up-and-down handle style could not have been produced by a couple of men in the same time. There is great need in both trade and private gardens generally of labour-saving appa-

ratus, and especially in anything relating to water. Among miscellaneous exhibits we noted some excellent tubs for large Palms, Ferns, Orange trees, and the like, which were made in two equal sections kept together by strong fastenings, so that these only had to be removed to examine the roots or for re-tubbing.

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 24.

ON this occasion the usual fortnightly show was supplemented by the Auricula Society's Exhibition, and the two combined produced the finest display that has been made at South Kensington this year. It was likewise a most interesting one, for the exhibits were of a varied character, and there was ample material to suit the tastes of the crowds that visited the exhibition. One hardly knew which to admire most, the Auricula show, the superb Roses from Cheshunt, the equally fine group of Clematises from Bagshot, the splendid collection of Daffodils from Messrs. Barr, or the Orchids, Cyclamens, Amaryllises, Pelargoniums, contributed by various others. New plants, too, were more numerous than usual.

First-class certificates were awarded to the following:—

MAXILLARIA HARRISONIÆ ALBA.—A new and very beautiful variety of an old and well-known Orchid. It differs in no way from the original except in colour; the sepals and petals are pure white and of wax-like texture, while the labellum is white and exquisitely lined and pencilled with purple. The perfume is quite as strong and as pleasant as in the type. It is a fine addition to garden Orchids, and a really useful ornamental plant. Exhibited by Mr. B. S. Williams, Upper Holloway.

AMARYLLIS ADOLPHUS KENT.—A seedling variety remarkable for the intensely deep crimson of its flowers, surpassing in richness that of A. Acramanni pulcherima, from which it is evidently descended. Its unique colour is its chief characteristic, for its flowers are but of medium size, and in form it is a little too funnel-shaped. Exhibited by the raisers, Messrs. Veitch & Sons, Chelsea.

ROSE MERVEILLE DE LYON.—A Hybrid Perpetual variety, having large, full, and finely-shaped white flowers, suffused with a delicate blush tint. It appears to be vigorous in growth and floriferous, and will, no doubt, become a standard variety. Shown by Mr. Turner, Royal Nurseries, Slough.

ODONTOGLOSSUM POLYXANTHUM GRANDIFLORUM.—The finest variety of this species, both as regards size and colour, that has been seen in this country. The flowers measure about 5 inches across the outstretched flowers, and the petals and sepals are much broader than usual. The ground colour is white, inclined to green, and heavily blotched with chestnut-brown. Exhibited by Mr. Woolford, gardener to Mr. Lee, Downside, Leatherhead.

MIMULUS GRANDIFLORUS BRILLIANT.—A very beautiful variety, having flowers about 2 inches across, of a glowing rich crimson inclined to scarlet, a colour seldom seen even among the variable Monkey Flowers. In habit of growth the plant is admirable; in short, it is one of the finest varieties we have seen. Exhibited by Mr. R. Dean, Ranelagh Road, Ealing.

CLEMATIS JOHN BROWN.—A single-flowered variety of the lanuginosa type. The flowers are large, the petals broad and of firm substance, and of a rich uniform purple. Shown by the raiser, Mr. Noble, Sunningdale Nursery, Bagshot.

AZALEA ANTIGONE.—A variety of the Indian Azalea, with large, semi-double flowers, pure white, striped and flaked with purple. Quite distinct from older varieties and a valuable acquisition. From Mr. Turner, Slough.

PRIMULA DOLOMITES.—A new species, having a tuft of broad-toothed edged foliage, from which are produced the flower-stems, which rise 3 inches

or 4 inches high. The flowers, borne in stalkless umbels terminating the flower-stem, are about an inch long, tubular, and gradually opening wide at the mouth. The colour is a bright chrome-yellow, which makes it quite distinct from other cultivated species. It is a neat and pretty plant, and a valuable addition to hardy flowers. Exhibited by Mr. J. T. Llewelyn, Penllergare, Swansea.

SCUTICARIA DODGSONI.—A new and handsome species intermediate between S. Hadweni and S. Stechi. It has long terete drooping foliage; the flowers are some 2 inches across; the sepals and petals are yellowish, heavily blotched with chocolate-brown; the labellum is boat shaped, and has purplish markings on it. It is a distinct and handsome Orchid. From Mr. B. S. Williams.

NARCISSUS PRINCESS MARY.—A very beautiful variety of the incomparabilis type, having large full flowers with white petals, and a broad shallow pale yellow crown; one of the finest of the race. Exhibited by Messrs. Barr and Sons, Covent Garden.

ROSE WHITE BARONESS.—A pure white flowered sport from the well-known and highly-prized Hybrid Perpetual Baroness Rothschild, from which it differs only in colour. It will no doubt prove one of the finest of white Roses. From Messrs. Paul and Son, Cheshunt.

POT ROSES.—A fine feature of the show was an extensive collection of pot Roses from Messrs. Paul & Son's nurseries, Cheshunt. There were about three dozen specimens in all, some being large fan-trained plants, as perfect as could possibly be as regards profuseness of flower and vigour of plants. The sorts represented by these large specimens were Edouard Morren, Comtesse de Serenye, Duke of Edinburgh, Magna Charta, La France, Céline Forestier, Louis Van Houtte, and Comtesse Riza du Parc, the last a lovely new Tea variety, with flesh-tinted flowers of good size and fine shape. The other plants in the group were for the most part standards, and comprising admirably grown plants of La France, Marie Van Houtte, Madame Falcot, Triomphe d'Alençon, Madame Margottin, Maréchal Vaillant, Moiret, and Catherine Souper. Besides these there was the new White Baroness, perhaps the best pure white Hybrid Perpetual we have, the flowers being large, full, and pure in colour. There was also shown a new variety named Ulrich Brunner, having a splendid full flower of a bright cerise, and one that will inevitably become a standard Rose. Rarely have Roses been seen in such perfection in April, and Messrs. Paul provided a real treat for the visitors. The group was awarded the first prize of £6 offered by the Society for the finest group of Roses.

CUT ROSES.—A silver Banksian medal was deservedly awarded to Mr. W. Rumsey, Joynings Nurseries, Waltham Cross, for an extensive collection of cut Roses, numbering twenty dozen trusses, which, having regard to the early date, did the grower considerable credit, as scarcely a bad bloom could be seen; on the contrary, the majority were of first-rate quality. The collection, too, was a thoroughly representative one as regards varieties, there being a fine selection of Hybrid Perpetuals and a similarly fine one of Teas. Some two dozen blooms of Maréchal Niel Rose were as fine as could possibly be seen, all the flowers being large, full, and highly coloured. Of such beautiful sorts as Anguste Rigotard, Dr. Andry, Star of Walham, Marquis de Castellane, Marie Baumann, Annie Laxton, Paul Néron there were some blooms as fine as could be seen at any July show. Taken altogether, this was a remarkable collection, and Mr. Rumsey deserves the thanks of the community for bringing together such a gathering of April Roses.

ORCHIDS.—A collection from Messrs. Thomson and Sons, Clovenfords, Galashiels, N.B., contained many choice and beautiful things. A gathering of about a dozen spikes of Vanda suavis and varieties of V. tricolor showed plainly how well the Vanda is grown and flowered at Clovenfords, and what uncommonly fine varieties there are there; but as those shown were unnamed, we cannot particularise any. Other cut spikes were of Cattleya

amethystina, one of the best forms, a wonderfully fine Dendrobium Wardianum nearly 5 inches across, and another with plum-coloured markings, splendid forms of Cattleya Mossiæ and Mendellii, and a grand variety of Cypripedium villosum called aureum, with flowers fully a third larger than usual, and with a striking suffusion of yellow in the flower. Messrs. Thomson also showed a plant of the new Cattleya Gaskelliana, which is unquestionably a magnificent Orchid, having very large-spreading flowers with delicate mauve sepals and petals, and a wide shallow labellum with a yellow throat and heavily blotched with brilliant amaranth, and with a broad frilling of white. The plant shown bore two spikes, one carrying two, the other three blooms. An Odontoglossum in the way of Ruckerianum was likewise shown. It is a very handsome variety, but distinct both from Ruckerianum and Andersonianum (flowering plant of which was shown for comparison), but appears to be intermediate between the two. The plants shown bore a spike with five branches. A silver Banksian medal was awarded to Messrs. Thomson for their attractive collection.

A similarly fine collection of cut Orchid flowers was sent by Dr. Paterson, from Fernfield, Bridge of Allan. It comprised some exceptionally fine spikes of Vanda suavis and tricolor, Lycaste Skinneri, Odontoglossum Halli, Masdevallia Veitchii, and various others, all of which bore evidence of skilful culture. A bronze Banksian medal was awarded.

A marvellously fine variety of Odontoglossum called Stevensi was exhibited by Mr. Stevens, from the Duke of Sutherland's garden at Trentham. It was, without exception, the finest variety of the Alexandræ type that has yet come under our notice. The flowers are large and have broad overlapping petals and sepals pure white, and blotched all over their surfaces with a pale cinnamon colour. The plant shown bore a long arching spike, and was a most attractive object.

A handsome unnamed variety of Odontoglossum came from Messrs. Jackson, of Kingston. It is near that named O. Wilckeanum, and is unquestionably a distinct and beautiful plant.

Messrs. Sander & Co., St. Albans, exhibited a plant of Cypripedium ciliolare, a new species in the way of C. Argus, and quite as handsome; also a flowering plant of the new and rare Phalenopsis Sanderiana, which, however, did not represent the plant so finely as the plants that have lately bloomed in Sir Nathaniel Rothschild's garden at Tring Park. Messrs. Sander also had a panful of the charming Pinguicula caudata, which they were the first to introduce to cultivation from Mexico. A panful of flowers was a pretty sight, and we observed several gradations of tint in the flowers. Among the Orchids shown by Mr. B. S. Williams were some well-flowered plants of Odontoglossum vexillarium, of which there was a variety called splendens, having large blossoms of the richest and deepest tint of any we have seen, a contrast to the washy forms one often meets with. In the same collection was a specimen of D. densiflorum, with a dozen spikes all expanded; another of D. thyrsiflorum and of D. Wardianum with long wreaths of bloom.

AMARYLLISES.—A group of seedlings from Messrs. Veitch, numbering about a dozen plants, included some wonderfully fine sorts, as perfect in every point as any that have been shown previously by this firm. Among the most striking were Mrs. Burbidge, flower very large, bright freckled carmine, with a conspicuous band of white running through each petal; Schiller, large, with broad reflexed petals of a salmon-pink, striped with white; W. S. Parker, remarkable for its intensely deep crimson, but a rather small and ill-shaped flower; Goethe, with funnel-shaped flowers of a brilliant netted crimson, and white striped; Corneille, large and fine in form, crimson, freckled and mottled with white. The others shown were named Mar-mion, Molière, Sappho, Marianne, and Queen of Holland. It is now some six weeks or two months since Messrs. Veitch began to exhibit their Amaryllises this year, and still they have other seedlings to flower, so that the Amaryllis season now

extends over a long period. A new double Azalea, named *Hermosa*, also came from Messrs. Veitch. It is a profuse flowerer, the colour being a deep rose-pink, and the flowers are large and quite double.

CYCLAMENS AND AMARYLLISES, all finely flowered, formed a large and attractive group, from Mr. B. S. Williams, Upper Holloway, who was awarded a silver Banksian medal. The Cyclamens were of the large bold-flowered strain, known as Williams' Improved, and the Amaryllises comprised such remarkably fine sorts as Dr. Masters, which we have so often praised; William Pitt, with small flowers, but of a splendid rich crimson colour; Mrs. Gordon, large crimson edged white; Guiding Star, Mrs. Browne, Princess of Prussia, and the lovely white variety, Mrs. B. S. Williams. Among miscellaneous plants we noted in Mr. Williams' collection the new *Sarracenia Fildesi*; a double *Cineraria*, *Vortigern*, with bright violet flowers; *Azalea La Pucelle de Gand*, a large single white; and a beautiful small-flowered, semi-double flowered variety called *Duke of Edinburgh*.

RHODODENDRON EXONIENSE.—A large specimen, between 4 feet and 5 feet through, of this new *Rhododendron* was exhibited by Mr. Robert Veitch, of Exeter. It carried a profusion of white blossoms about the size of those of an ordinary Indian *Azalea*. They are white, faintly suffused with pink. It is one of the finest of this section of *Rhododendrons*, and is sure to become popular. Some small plants of it accompanying the large specimens were sufficient to prove that it is a profuse flowerer in even a very small state. Another *Rhododendron* named *gloxiniiflorum* was also shown by Mr. R. Veitch. It has large transparent flowers copiously spotted on the inside of the corolla; the trusses are large and handsome.

RHODODENDRONS and Indian Azaleas in one bold and effective group similar to that exhibited on the last occasion came from Messrs. Lane's nursery, Great Berkhamstead. Of course no other than a fine collection could be expected of such veteran exhibitors, but we thought these *Rhododendrons* finer than ever, all being large bushy standards completely smothered with trusses of bloom. Their natural, untrained appearance greatly added to the charms of both *Rhododendrons* and *Azaleas*. A silver gilt medal was awarded. A group of Indian *Azaleas*, consisting of admirably flowered specimens, came from Mr. Bown, Erdleigh, Gunnersbury, who was awarded a bronze Banksian medal.

CLEMATISES.—A splendid group of Clematises was shown by Mr. Noble, of the Sunningdale Nursery, Bagshot, who has paid a deal of attention to the cultivation and improvement of these beautiful flowers. The collection numbered some thirty plants, all in 12-inch pots and trained on cone-shaped wire trellises. There were single and double flowered sorts amongst them, and two were quite new. These were named *Krao*, with large violet-purple flowers and a conspicuous tuft of white stamens in the centre; and *John Brown*, of a splendid deep purple, having large broad petalled flowers. Both of these may be considered acquisitions, being distinct from other varieties of similar colours. Among the rest were such beautiful sorts as *Aurora*, *Proteus*, and *Undine*, all with double rosette-like flowers of various shades of violet; and *Elaine*, also a double of a bright purple. Of the singles the finest were *Maud Branscombe*, pale pink; *May Queen*, rich mauve; *Princess Beatrice*, delicate porcelain blue; *Duchess of Albany*, pure white; *Lord Giffard*, deep violet; *Margaret Dunbar*, bright purple; *Miss Bate-man*, white shaded with blue; and *The President*, the finest purple Mr. Noble has, the colour being intensely rich and deep and very uniform. For this attractive and much admired group Mr. Noble received a silver Banksian medal.

Cut *Pelargonium* flowers, representing single zonals, double zonals, and double Ivy-leaved sections, in their finest varieties came from Messrs. Cannell, of Swanley, who alone could make such a grand display of *Pelargonium* blooms in the middle of April. We have seen the zonal varieties quite as fine from Swanley, but never had we seen the Ivy sorts in

such fine condition, not even in the middle of June. There were about a dozen sorts shown, and as they were of the finest we give the names as being a good representative selection: *Comte H. de Choiseul*, cerise; *Mad. Crousse*, pink; *Comtesse H. de Choiseul*, bright amaranth; *Madame Pages*, deep mauve; *Albert Crousse*, bright carmine; *George Gordon*, deep mauve; *Mad. E. Galle*, pale mauve; *Eurydice*, deep mauve-pink, one of the finest; *M. Dubus*, amaranth; and *La Perle*, deep mauve. These can be recommended as being the finest of the numerous sorts now grown, but even among the large quantities Messrs. Cannell grow it could not have been an easy task to have cut such enormous trusses of bloom so early in the season. The zonals were the admiration of everyone, their brilliant hues lighting up everything about them. The same exhibitors also showed a fine potful of an early *Gladiolus* with salmon-tinted flowers of the *ramosus* type, and a basketful of plants of the double *Chrysanthemum coronarium*, aptly named the *Aurora Marguerite*. The flowers, about the size of a crown-piece, are as double as they could be, and of a clear chrome-yellow. For winter and spring bloom it will be a first-rate plant, and the dwarf profusely flowered specimens shown on this occasion admirably represented the variety. A silver Banksian medal was awarded to Messrs. Cannell & Sons.

From the genial climate of Bath Mr. Hooper brought from his nursery at Widcombe Hill some six dozen blooms of the *Pansies* he grows so finely, chiefly show varieties, also a smaller number of *Carnations*, which were excellent for the season. Cut blooms of *Maréchal Niel Rose* also came from Mr. Hooper. A double form of *Anemone coronaria* called *splendens* was shown by Messrs. Collins & Gabriel. It was indeed a splendid variety, as fine as we have ever seen, the blooms being fully double and of a vivid scarlet colour. A few such *Anemones* as this in a spring border would doubtless make a charming picture in any garden.

A fine variety of *Imantophyllum miniatum*, called *Mrs. Laing*, was shown by Messrs. Laing & Co., Forest Hill. It is remarkable for its large and finely shaped flowers of a bright glowing orange-red, as fine as the best of the Belgian varieties when seen at its best. A single yellow-flowered Wallflower called *Cranford Beauty* was exhibited by Mr. J. Graham, of Cranford. It is a vigorous growing sort, about a foot high, and very bushy, and the unusually large flowers are of a glowing clear yellow. It will be a useful plant for spring gardening, but in the absence of other yellow flowered Wallflowers to compare with it we are unable to speak of its distinctness.

TWO NEW *AZALEAS* were brought by Mr. Turner from his nursery at Slough, named *Comte de Kerchove* and *Hermosa*, both of which we thought uncommonly fine. The first has large salmon-pink flowers copiously blotched with crimson and edged with white. The other was the same as that shown by Messrs. Veitch. Mr. Turner also showed a most singularly coloured *Pelargonium* called *Dresden China*, having large flowers flaked and striped with white and pink, somewhat like the old York and Lancaster Rose. It belongs to the decorative class, but is distinct from any yet raised.

CLEMATIS COCCINEA.—The scarlet-flowered species figured a short time since in *THE GARDEN* was exhibited by Messrs. Carter, but the plant did not represent the species at its best, the colour being much brighter later in the season. The same firm also shows an attractive variety of *Primula Sieboldi* called *grandiflora* and a basketful of their new *Viola* called *Carter's Perpetual Blue*, which is said to produce a perpetual crop of its rich, deep purple flowers even throughout the winter. The *loop Petticoat Daffodil* was shown finer by Mr. Douglas, of Great Gearies, Ilford, than we had hitherto seen it. The plants, about half-a-dozen bulbs in 6-inch pots, were a mass of large golden yellow blossoms, which, being uncommon at a show, won a fair share of admirers. Mr. Douglas was worthily awarded a cultural commendation.

THE FRUIT AND VEGETABLE COMMITTEE had very little to do on this occasion, as there were but three exhibits. These were a new hearing *Kale* shown by Mr. Read, and which was considered worthy of a first-class certificate; Mr. Ellis, Biggleswade, sent some admirably grown examples of *Tender and True Cucumber*, and Mr. Kershaw sent samples of his new *Paragon Rhubarb*, which is said to be a first-rate variety—"very prolific, and never runs to seed."

SCIENTIFIC COMMITTEE (Mr. Loder in the chair):—

Grafted Conifers.—Mr. Noble sent a specimen to show the protuberant growth produced by *Picea nobilis* grafted on *P. pectinata*.

Abies Nordmanniana attacked by insects.—He also sent a bough of this tree terribly infested by coccus, to which the entire tree appeared to be succumbing.

Lilium Thomsonianum.—Mr. G. F. Wilson showed a plant bearing several spikes of flowers which have as yet been somewhat seldom seen. The question was raised whether it was a true *Lily* or *Fritillary*, which are distinguished by the form of the honey nectary, that of *Lilies* being a long groove, as in *L. Thomsonianum*, and in *Fritillaries* a deep circular pit.

Rhododendrons.—Mr. Boscawen sent several sprays of various forms, all having been grown in the open air, but amongst *Pir* trees, which, Mr. Llewellyn observed, constitutes an excellent protection, viz., *R. Thomsoni*, *R. fulgens*, a pink one, variety of *R. arboreum*, introduced, he believed, by Sir J. D. Hooker, a white seedling of much beauty, and Mrs. Townshend Boscawen. Mr. Llewellyn brought cut blooms of *R. arboreum album* or *ochraceum* (?) having a white, waxy, campanulate corolla very slightly spotted with black, the foliage having an ochraceous tomentum below; the tree is 15 feet in height. He also exhibited trusses of *R. Thomsoni*, *R. campanulatum*, *R. arboreum*, *R. Wallichii*, and *R. niveum*—all blooming now in the open air. He observed that they would have been over at this time had not the buds been held back by the cold for a month before the March frost began. They are now blooming as if there had been no frost.

Arum italicum.—Dr. M. T. Masters brought a specimen of this plant from Folkestone, the first instance of its occurrence in Kent, other habitats being Cornwall and Isle of Wight. It differs from the common *Arum maculatum* by having hybernal leaves, the petiole longer than the blade (over 12 inches), while the basal lobe of the sagittate leaf is larger as well as the spathe.

Primula clatior.—Mr. Boulger showed various specimens of this plant received from Mr. Christie, of Saffron Walden, described as scentless, but which had a marked odour of *Apricots*; after a coppice had been cut down it appears to run into several monstrous forms, such as fasciation, &c. He noted that single flowers on abbreviated peduncles come from lateral points on the rootstock, but the pedunculated umbel from the summit. This latter form, Mr. Henslow observed, is the one horticulturists now aim at securing in their numerous *Polyanthus*-formed *Primulas*, at the same time suppressing the isolated flowers which arise. He also showed a supposed hybrid between *P. officinalis* and *P. elatior*.

Sclerotium in Potato.—Mr. A. Stephen Wilson forwarded tubers diseased and several microscopic slides of preparations of the sclerotia, which were forwarded to Mr. Murray for examination and report.

NATIONAL AURICULA SOCIETY. (SOUTHERN DIVISION.)

APRIL 24.

THE Auricula season has again returned, and fanciers of this interesting flower are once more engaged in friendly rivalry with their plants. In the conservatory at South Kensington on Tuesday last the southern division of the Auricula Society held its annual show, which, taken as a whole, was finer than any that has hitherto been held, though perhaps the individual plants shown were not so fine as on previous occasions. This

was, however, chiefly attributable to the inclemency of the weather that we have lately had. Among the exhibitors there were the same familiar faces and also a few new-comers, a circumstance which plainly points to the fact that the Society has not been unsuccessful in its endeavour to popularise and foster the culture of one of the oldest and best known of our spring flowers. It was a noteworthy fact that fully one-half of the prizes went to exhibitors from the north—those from Warrington, Halifax, and Manchester—that well-known Auricula grower, Mr. Horner, of Kirkby Malzeard, being particularly successful. The chief prize winners in the south, as usual, were Mr. Douglas, of Ilford, and Mr. Turner, of Slough, both of whom showed some remarkable productions. The show altogether was a most attractive one, but visitors were far more charmed with the loveliness of the selfs and alpine varieties than by the show varieties with their green, grey, and white-edged flowers that are looked upon by the uninitiated in the light of curious monstrosities. These self and alpine varieties are evidently becoming more generally grown every year. The schedule was so arranged as to give both large and small cultivators a chance of competing, but we should like to see ten times the number of exhibitors. Subjoined is a detailed account of the exhibition, and those who desire to make a selection of the best kinds cannot do better than make a note of the names of those shown in the different classes.

Collections.

In the class for twelve, Mr. Douglas and Mr. Horner were equal firsts. In the collection of the former there were Prince of Greens, Smiling Beauty, Mabel, Conservative, George Lightbody; and of selfs, Pizarro, Blackbird, Charles Perry, and a few unnamed seedlings made up the dozen. Mr. Horner had R. Headley, Meiklejohn, Monarch, George Lightbody, John Simonite, Champion, and Acme among shows, and Beatrice, Mrs. Douglas, Heroine, and Blackbird among selfs. Mr. Pohlman, Halifax, had the third collection, and in it were fine examples of Brunette, Mrs. Douglas, and Garibaldi, three of the most beautiful selfs. The fourth collection was from Mr. J. T. Llewelyn, Penllegare, Swansea, and contained good specimens of Grey Friar, Ne Plus Ultra, Lovely Ann, and other fine show varieties.

The class for six plants was represented by only two collections, the best being from Mr. Pohlman, who had in his lot Ajax, Prince of Greens, Trail's Beauty, George Lightbody, Brunette, and Acme, all admirable specimens. Mr. Douglas had the second best six, which included besides two seedlings, Duke of Albany, Blackbird, Conservative, and Confidence.

The class for four was more numerous; there were eight competitors. The best came from Mr. Penson, Ludlow, who had Acme and George Lightbody in fine condition, Prince of Greens, and Topsy. Mr. Barlow was second with a green-edged seedling called Goldfinch, Alexander Meiklejohn, Smiling Beauty, and a new seedling self called Adonis. Mr. Brockbank, of Didsbury, was third with a fine plant of George Lightbody, also John Simonite, Lovely Ann, and a beautiful new seedling self. In Mr. Fife's collection, which was fifth, there was a good plum-coloured self called Formosa. Mr. Bolton, of Warrington, showed the fourth collection of four, having Alderman Brown, Prince of Greens, Reliance, a seedling self, and a good specimen of Glory. In Mr. Dean's sixth collection was a capital plant of Read's Brilliant (one of the finest selfs), Lancashire Hero, New Green, and an un-named seedling. Mr. Dombbrain and Mr. Turner showed the other two collections, and both had some excellent selfs, particularly one in Mr. Dombbrain's lot called Metropolitan, which was uncommonly fine.

The class for pairs was a very numerous one, as the small growers had a chance of competing in it. There were no fewer than fourteen exhibitors in this class. The best two were from Mr. Barton, who had Colonel Taylor and a seedling self called Carboneil; Mr. Penson was second with Ludlow and Prince of Greens, Mr. Brockbank third with Reliance and a seedling self (very handsome), Mr.

Turner fourth with Topsy and Beauty, Mr. Rowan fifth with Lovely Ann and Pizarro, and Mr. Bolton sixth with Frank Simonite and Prince of Greens. Messrs. Dean, Catley, Kew, Henwood, Dombbrain, and Phillips also showed in this class.

Single Specimens.

GREEN-EDGED VARIETIES.—There were no fewer than thirty-eight single specimens of green-edged sorts. Mr. Horner was first with a seedling raised by Simonite, Mr. Pohlman second with Col. Taylor, Mr. Penson third with a seedling, Mr. Horner fourth with a seedling, Mr. Brockbank fifth with Col. Taylor, Mr. Pohlman sixth with Imperator, Mr. Penson seventh with Col. Taylor, and the same exhibitor eighth with Talisman.

GREY-EDGED.—Of these there were over half a hundred single specimens shown. The first was George Lightbody from Mr. Pohlman; the same variety, shown by Messrs. Douglas, Horner, and Pohlman, took the second, third, and fourth prizes respectively; Mr. Brockbank was fifth with Alexander Meiklejohn, Mr. Douglas sixth with Jumbo, Mr. Pohlman seventh with G. Lightbody, and the same variety was shown by Mr. Douglas for the eighth prize.

WHITE-EDGED.—About seventy plants were shown in this class. The best was Conservative, from Mr. Douglas; Read's Acme, second, from Mr. Brockbank; John Simonite, third, from Mr. Horner; Silvia, fourth, from Mr. Douglas, who also was fifth with Dr. Kidd, and sixth with Conservative; Mr. Brockbank was seventh with Acme, and the same sort from Mr. Douglas was eighth.

SELFS.—About a hundred self varieties were shown in the single specimen class. Heroine, a very beautiful variety, took the first four prizes, a good proof of its worth. All four were shown by Mr. Horner, who raised it; Mr. Pohlman was fourth with Blackbird, and the same sort from Mr. Horner, was sixth; Mr. Brockbank was seventh with Cymbeline; and Ringdove, from Mr. Horner, was eighth.

ALPINE VARIETIES.—In the class for twelve Mr. Turner was first, with a very fine collection of such first-rate sorts as National, Sensation, E. S. Dodwell, Diadem, Mariner, Superb, Mrs. Thompson, Vesuvius, Tennyson, Phoenix, Raphael, and Artist. Mr. Llewelyn was second, his collection being remarkable for several fine unnamed seedlings. Mr. Douglas had the third collection, which comprised excellent plants of George Lightbody, Ada Hardwidge, and Rosamond. There were four sets of six plants. Mr. Turner was first with Troubadour, F. A. Dickson, Mariner, John Ball, John Brown (new), and Sensation—a very fine half dozen. Mr. Pohlman was second, five out of the six being seedling laced varieties, some of which were uncommonly fine. Mr. Llewelyn was third, and Mr. Douglas fourth.

SINGLE SPECIMEN ALPINES, with gold centres, were numerous, there being about two dozen shown. Mr. Turner took all the six prizes in this class. For the first he had a seedling called Dr. Hogg, for the second Unique, third Vista, fourth Roysterer, fifth E. R. Cutler, sixth John Brown, all new seedlings, and first-rate in their respective colours. There were about thirty white or cream centred varieties, Mr. Turner taking all the six prizes offered. He had new seedlings called Olivette, Bayard, Mabel, J. D. T. Llewelyn, Talisman, and Milton.

THE FANCY VARIETIES, so odd looking compared with the beautiful selfs or alpine, do not appear to be much grown, judging by the small numbers of them shown. Mr. Douglas had the best dozen, and Mr. Bolton, of Warrington, the next best, while Mr. Dean was third. In one or two the collections of fancy varieties there were some pretty laced flowers, which, being so distinct from any other race, might well be placed in a class by themselves.

POLYANTHUSES.—The class for six plants was represented by four collections. Mr. Barlow, a well-known northern grower, was first with excellent plants of Exile, George IV., Lord Lincoln, Cheshire Favourite, Prince Regent, and Sunrise.

Mr. Brockbank, of Didsbury, was second with Exile, George IV., Cheshire Favourite, Sir Sidney Smith, Beauty of England, and Lancer, all good examples. Mr. Llewelyn was third with President, Exile, Lord Morpeth, George IV., Prince Regent, and Cheshire Favourite. In Mr. Douglas' fourth set were fine plants of Lancer, Cheshire Favourite, and Exile. There were six sets of threes; Mr. Barlow was again first with Cheshire Favourite, Exile, and George IV. Mr. Brockbank was next with Sir Sidney Smith, Exile, and George IV. Mr. Douglas third with Cheshire Favourite, George IV., and Lancer; and Mr. Llewelyn fourth with Lancer, President, and Cheshire Favourite. Single specimens numbered about fifty. Mr. Brockbank was first with a fine specimen of Cheshire Favourite, Mr. Llewelyn second with Exile, Mr. Brockbank third with George IV., Mr. Barlow fourth with John Bright, Mr. Brockbank fifth and sixth with Nonpareil and Lancashire Hero respectively.

PRIMULAS were better and more numerous shown than we had hitherto seen them here. A really fine collection of twelve plants was shown by Mr. Llewelyn for the first prize. It comprised a fine specimen, over a foot through, of *Primula Sieboldi*, and also of the variety *ilicina*; also *P. rosea* (an admirable specimen), *P. japonica*, *P. Auricula*, *P. verticillata*, *P. involucrata* var. *Munroi*, and *P. Pallasi* with pale yellow flowers. Mr. Llewelyn also showed the second collection, and Mr. Dean had a fine group of *P. Sieboldi*—all the best varieties, and well grown. The principal prizetakers in the classes for border Polyanthuses and Primroses were Mr. R. Dean, Mr. Brockbank, and Mr. Hooper. The exhibits of Mr. Dean were particularly fine, as were also the double Primroses from Mr. Brockbank, who also had seven or eight remarkable seedlings, the offspring of Lord Lincoln, Exile, Cheshire Favourite, &c. They are as follows: John o' Groat, very fine, dark; Red Exile, very like the black variety; Excellence, a very pretty dark; Lord Derby, a grand tall variety; Beauty of Brockhurst, rivalling the old Beauty of England, and like it; Black Diamond, a very black ground; and Nonpareil.

We must not omit to mention the important collection of Primroses from Mr. Waterer, Knap Hill Nursery, Woking, which contained many beautiful sorts, and which were shown to pretty effect in long boxes. A silver medal was awarded.

NEW AURICULAS AND POLYANTHUSES.—Of these there was a goodly number both of show and alpine varieties, Messrs. Horner, Barlow, Brockbank, Douglas producing the former and Mr. C. Turner the latter. Prizes were awarded for the best green-edged Auricula, the first prize going to Mr. Barlow for a medium-sized, but very bright-looking variety of high-class quality—tint, paste, body colour, and edge all good; second, the Rev. F. D. Horner with Monarch, a large and very fine flower of excellent qualities. In the grey-edged class the Rev. F. D. Horner was first with Ajax, a large, very bright, and correct flower that promises to take a high position in its class; second, Mr. J. Douglas, with Miss Lodge, a very pleasing variety of large size and excellent qualities. In the white-edged class some seedlings were shown, but they were not considered worthy an award. In the self class Mr. Samuel Barlow was to the fore with a very fine lot of pale plum-coloured flowers, very smooth and correct. Adonis was placed first and Caruncle second, both raised by Mr. Barlow, and likely to take high rank as exhibition flowers. The premier Auricula in the whole show was Conservative (Douglas), a very pleasing white-edged variety, with six finely expanded pips. In the classes for new alpine Auriculas, which are divided into gold centres and white centres, Mr. C. Turner was awarded both prizes in each division. The best gold centres were Dr. Hogg and Unique, very bright and effective edged or shaded flowers of the finest quality; the best white centred varieties, Olivette and Bayard. The four foregoing varieties were quite up to the mark of the splendid flowers raised at Slough.

Prizes were also offered for gold-laced Polyanthus, black grounds and red grounds. Mr. W. Brockbank was the only exhibitor of these, and received the first and second prizes in the class for black grounds, staging Black Diamond and Nonpareil, two flowers of high-class quality and great promise. No award was made in the class for red ground Polyanthus.

First-class certificates were awarded to the following new alpine Auriculas from Mr. C. Turner: Bayard, white centre; Dr. Hogg and Roysterer, golden centres. A first-class certificate was awarded to Horner's Ajax for its excellent qualities.

ROYAL BOTANIC.

APRIL 25.

THE second spring show of this Society was held on Wednesday last in the Regent's Park Gardens. It was of much the same character as that at South Kensington, on the day previous, with the exception of exhibits shown in the competitive classes and a few miscellaneous groups. Messrs. Paul were there with their superb group of pot Roses from Cheshunt; also Mr. Rumsey, from Waltham Cross, with his extensive gathering of cut Roses; Messrs. Barr had their fine group of Narcissi; Messrs. Lane, Rhododendrons; Messrs. Veitch, Amaryllises; Mr. B. S. Williams, Orchids, Cyclamens, and Amaryllises; and Mr. Noble, Clematises. In addition to these there was a beautiful group of Cyclamens, numbering about half-a-hundred plants, from Mr. Little's garden at Hillingdon Place, Uxbridge. This group, well diversified, as it was, in colour, was greatly admired, and well worth the silver medal awarded to it. From Capt. Patton's garden in the Alpha Road came a fine group of Narcissi and other hardy flowers, which, though gathered from a London garden, were specially noteworthy. There were over fifty varieties of Daffodils, comprising most of the choicest sorts in the Ajax, incomparabilis, and poeticus sections. The handsome Emperor, Empress, Horsfieldi, and some of the Leeds forms were particularly fine, as were also the poeticus varieties. These were supplemented by such choice hardy plants as Zephyranthes Treatie, Triteleia uniflora, Fritillaria latifolia in variety, and some uncommonly fine plants of Primula cashmeriana, one of the finest of the denticulata type. Most of these were in narrow-mouthed glasses, in some cases plugged in pots of sand to steady them, but in all cases care was taken to hide the receptacles as much as possible. One could wish that Mr. Barr would take a hint from Captain Patton and exchange his blacking-bottles for receptacles that would better suit his Daffodils which he shows in other respects so admirably. We ought not to omit to mention some very fine plants of Begonia semperflorens shown by Captain Patton, which were a credit to his gardener. The flowers were larger and whiter than usual, and we learnt that it was a distinct variety, bearing the name of grandiflora. A small, but showy group of plants was exhibited by Messrs. Cutbush from their Highgate Nurseries. It consisted chiefly of New Holland plants, their great speciality, but the most striking was a collection of small bushes of Azalea mollis in several varieties. These were all densely flowered, their colours varying from pink, yellow, and salmon to almost white, a striking display, rendered all the more attractive by a fringe of Maiden-hair Fern.

The exhibits in competition for the prizes offered were none of them very remarkable, and though there were 15 classes in the schedule, some even of this number were not represented. Stove and greenhouse plants were shown by three or four in the nurserymen's class. The best collection of a dozen from Messrs. Reed were small, but neat, well flowered and fresh, and were decidedly superior to the rest. It was made up of the ordinary run of exhibition plants, such as Azaleas, Aphelexis, Heaths, and the like. Lady Goldsmid's gardener showed in the next best collection a remarkably fine specimen of the rarely seen but pretty, Hibbertia Reedi, also of Adenandra fragrans

and Leucopogon Richei, both comparatively rare, and the last an extremely pretty Australian shrub that should be grown in all gardens if only for cutting from. In Mr. James's third collection was a grand specimen of Anthurium Andreanum with six fine spathes, and an uncommonly fine variety of A. Scherzerianum, with spathes as large almost as those of the much-prized Ward's variety. In the other collection was a plant of Dendrobium thyrsiflorum with eight spikes. If the best dozen could have been picked out of these four collections, it would have made a very creditable display. Azaleas were not very remarkable except the collections from Mr. Turner and Mr. Ratty, both well-known Azalea exhibitors, who took the first prizes among nurserymen and amateurs. Mr. Turner's plants especially were remarkable for their trim appearance, not large, but perfect in every point, and a capital selection of varieties, among which were such beautiful ones as M. Thibaut, Comtesse de Flandre, Duc de Nassau, Reine des Pays-Bas, and Apollon, perhaps the finest of all whites.

The Roses of Messrs. Paul were the only ones shown in the competing classes, and fine they were, better even than on the previous day at Kensington. The nine included such standard varieties as La France, Mad. Lacharme, Anna Alexieff, Céline Forestier, Comtesse de Serenye, Mad. St. Joseph, and John Stuart Mill, all grown and flowered in perfection. There was only one collection of nine Pelargoniums, and this was from Mr. Turner, of Slough. All the plants were large and perfect specimens considering the early date. Nearly all were decorative sorts, such as Duchess of Bedford, Venus, Duchess of Edinburgh, Lady Isabel, La Patrie, Joe, Sappho, and Duchesse de Morny, all of which are excellent for early flowering. Cinerarias were shown by Mr. James and Mr. Wiggins, but the former was invincible, as his group of nine plants in point of quality of the blooms carried so much weight, but as regards culture there was little to choose between them, for both were excellent in that respect. Mr. James certainly carries everything before him in Cinerarias, for he is a long way ahead of everyone else. The new sorts he showed on this occasion were simply perfection. Amaryllises were not much compared with those of Messrs. Veitch, but Mr. Baxter's first prize lot contained one or two that were remarkable in point of colour, particularly that named W. S. Parker, which was as rich and brilliant in tone as could be. That named Percival was also a good sort in Mr. Baxter's collection. The other six were from Mr. Little's garden, the most noteworthy of which were Othello, deep crimson; Queen Mab, and Lytton. The Auriculas were much the same as those shown at South Kensington the day before. Mr. Douglas and Mr. Turner were the leading prize-takers in the class for a dozen plants, and Mr. Turner also showed a group of alpine sorts which were much admired. There were two collections of hardy plants, the best being that from Messrs. Carter's Forest Hill Nursery, in which were admirable specimens of Iris pumila azurea, with sky-blue flowers; Primula Sieboldi grandiflora, very fine; Primula viscosa alba, a fine potful; and Myosotis elegantissima, a pretty variegated Forget-me-not. The others were not remarkable. Mr. Llewelyn's second best lot comprised Trillium grandiflorum, Anemone Robinsoniana, a delicately-tinted variety of A. nemorosa; Trollius europæus, Primula longiflora, Hutchinsia alpina, and a singular Allium with porcelain blue flowers from Biarritz.

NEW PLANTS.—The following new plants, in addition to those certificated, were shown on this occasion: Cattleya Mendeli delicata, from Mr. B. S. Williams; Cinerarias Charles Dickens, Captain Williams, Rupert, Mrs. Elliott, William Robinson, Azalea Hermosa, and Amaryllises W. S. Parker and Schiller, from Messrs. Veitch. From Mr. H. Little came Polyanthus Rayon d'Or, Azaleas Empress of India, La Pucelle de Gand, M. J. N. Verschaffelt, and Cyclamen Mrs. H. Veitch; Pelargonium Dresden China, Azalea Comte de Kerchove, and Hermosa, from Mr. Turner; Clematises Duchess of Albany, John Brown, Maud

Branscombe, from Mr. Noble; Azaleas Master C. Connell and Mr. T. Todman, from Mr. Todman; Auricula Miss Lodge, Lieutenant Charrington, and Duke of Albany, from Mr. Douglas; Azalea Duke of Connaught and Amaryllis Guiding Star, from Mr. B. S. Williams; Rhododendron gloxiniflorum, from Mr. R. Veitch; Primula cortusoides amœna grandiflora and Viola Perpetual Blue, from Messrs. Carter and Co. Messrs. Barr and Sons had the following new Daffodils: Narcissus Minnie Hume, incomparabilis pallidus, Princess Mary, Mary Read Vincent, Rebecca Syme, Primulinus, and Barri conspicuus. Mr. E. Baxter showed Amaryllis Percival; Mr. H. James, Clematis Norwood Beauty; Messrs. Paul and Son, Roses White Baroness and Ulrich Brunner.

BOTANICAL CERTIFICATES were awarded to Mr. B. S. Williams for Odontoglossum Alexandræ grandiflorum, Crinum Kirki, and Scuticaria Dodgsoni; and to Mr. James, Castle Nursery, Lower Norwood, for Odontoglossum Chestertoni, a fine variety.

FLORICULTURAL CERTIFICATES were awarded to Messrs. Veitch for Amaryllises Adolphus Kent, Mrs. Burbidge, Thomas Moore, and Queen of Holland; to Mr. James, Woodside, Farnham Royal, for Cinerarias Mrs. White, Lord Boston, and Shirley Hibberd, all excellent sorts; to Mr. Turner for Rose Merveille de Lyon, Azalea Deutsche Perle (a double white), and Azalea Antigone; to Mr. Douglas for Auricula Conserva (a grey-edged show variety); to Mr. Noble for Clematis Krao; to Captain Patton for Narcissus incomparabilis Princess Mary; to Mr. Little for Cyclamen Mrs. H. Veitch; and to Messrs. Barr & Son for Narcissus Minnie Hume, N. Princess Mary, N. bicolor, J. B. M. Camm, and N. Purity.

A list of awards will be found in our advertisement columns.

Carpet bedding (P.).—1, edging of Echeveria secunda glauca, or of Sedum glaucum; 2, groundwork of Herniaria glabra; 3, dot plants of Echeveria metallica, or of any other tall succulent; 4, line of Pyrethrum Golden Feather, or of Mesembryanthemum cordifolium variegatum; 5, Alternanthera paronychoides; 6, Alternanthera amabilis, or else Coleus Verschaffelti; 5 and 6 may have a central plant of Grevillea robusta, or of Dracæna australis lineata; 7, line of variegated Pelargonium, or of Centaurea.—W. W. H.

CATALOGUES RECEIVED.

Stansfield Brothers' (Southport) Alpine and Hardy Perennials.

Wrinch & Sons' (Ipswich and London) Garden Furniture.

Krelage & Sons' (Haarlem) Bulbous Plants.

Rawlings Brothers' (Romford) Descriptive List of Dahlias.

P. S. Williams' (Upper Holloway) New and General Plant Catalogue.

W. Paul & Son's (Waltham Cross) New Roses, Geraniums, &c.

W. B. Smale's (Torquay) General Nursery Catalogue.

R. Smith's (Worcester) Fruit Tree List and Rose List.

Fritillaria oranensis, planted in November on arriving from Algeria, came up early in March, before any other Fritillaries, and stood perfectly unhurt through the severe weather in the middle of the month, when the foliage of Primroses, Violets, and Anemones in the same situation was entirely destroyed. It is a very dark kind, with green stripes down the divisions outside.—G. J.

Names of plants.—Devonian.—The plant now so pretty in patches at Mentone is Linaria aureo-reticulata.—J. R. R.—A pale form of Lyncaste Skinneri (not uncommon).—J. C. T.—Erius alpinus.—Wakeman.—1, Anemone coronaria; 2, Saxifraga sarmentosa.—C. Mussell.—Phalenopsis Schilleriana. The names of the Heaths next week.—Busy Bee.—Solanum jasminoides.—L. B.—Narcissus incomparabilis fl.-pl. (Orange Phoenix).—R. M.—Filumna fragrans.—R. G.—Maxillaria Harrisoni.—T. G. K.—1, Dendrobium cambridgeanum; 2, D. crassinode; 3, Cyrtocochilus maculatum; 4, Kerria japonica variegata.—Mrs. Leach.—The old white Azalea indica alba; can be obtained from any good nursery.—S. K.—Dendrobium fimbriatum.—J. S.—Erica arborea. E. melanthera not likely to be hardy in Scotland.

No. 598. SATURDAY, MAY 5, 1893. Vol. XXIII.

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

ANTHONY WATERER AND THE PRIMROSES.

TO THE EDITOR OF THE GARDEN.

SIR,—That many Primroses should come from Knap Hill to a flower show is a sign of the times. I have long been under the impression that the only suitable background for a good man in that district was a fine bush of Rhododendron; but I am agreeably undeceived. The best things at the recent show at South Kensington were Primroses sent from Knap Hill, fine in vigour of growth and bloom. They were sent in large boxes; there was no trimming, dressing, or any of the usual "refinements" that go on among the hard-shell florists and "pip men." It was Nature unadorned, and supreme in every way over the poor little exhibits of the pip men. As Mr. Waterer showed the Primroses, we could get some idea of their value for garden decoration and of the splendid variety and colour that is among them. If one could have seen the very best colours he had, each in a separate box, then an idea would have been at once given of the high value of the plants for outdoor work. Beyond the merely hard-shell florist world there is a vastly greater world of men and women who love flowers for their beauty, and the truth is these people have a better knowledge of what is right and admirable than the florists as we now know them, with their little artificial complexities and limitations. There is not one in ten of the public who care, or ever could care, for flowers as these florists' flowers were shown. Let our nurserymen who care for such things go on in this way, and we shall soon see the old-fashioned florist take his due place. If Mr. Anthony Waterer or others will take up good races of Primroses and show what can be done with them, they will confer a great benefit on the public. There is the Auricula, the value of which has never been shown at exhibitions, owing to the delicate and pretty little forms seen at shows; but no fairer or hardier flower lives in Europe, and there would be no difficulty in the culture of charming hardy kinds, which grow out of doors as freely as Primroses, with bold leaf and beautiful flowers and buds. So long as a plant which is a native of the coldest mountains of Europe is housed in a greenhouse or cold frame we must expect that only the more delicate kinds will be developed under such circumstances. Not one person out of ten who know the Auricula knows its value in a moist, free soil out of doors. The Polyanthus also is an admirable plant in points which one can never see as shown in the old way. The one thing necessary in this connection is the selection of good, as opposed to bad and weak colours. There is a splendid range of fine colours in all these plants if people will but take the good, and not the merely curious and streaky varieties. We are rather too apt to fancy merely variegated kinds, and not take notice of the quality of colour which is the essential thing when the plant is seen in groups or masses. I do not wish only for decided colour; there are many wants in colour apart from decided colour. The softest colours may be extremely valuable, more so than many decided ones.

To rescue various beautiful hardy tribes of plants from the obscurity of the cold frame, and help to show their great value in garden decoration in all parts of this cold and rainy land of ours, is well worth the attention of our nurserymen, and I am very much obliged to Mr. Waterer for making so good a beginning. Up to the present time it is only in a private garden here and there that one meets with examples of the value of such plants; the great body of the trade have yet to be convinced of their importance. The pip men on the one side, few and weak, and the poor herbaceous border men on the other, succeeded between them in convincing the trade that there was nothing in hardy plants. Now, however, the scales are beginning to fall off their eyes.

J. M.

NARCISSI AND OTHER FLOWERS AT GUNTON.

I HAVE sent you a few flowers of the new incomparabilis forms of Narcissus, kinds that appeared to me to stand out with great beauty and distinctness from many others, viz., *N. Leedsi Hamel*, *N. sulphureus grandiflorus*, *N. aurantius expansus*, *N. Leedsi amabilis*. After reading for weeks past in THE GARDEN about the many fine kinds of Narcissus in flower in more favoured parts of the country as regards climate, the longing to see them open puts one in a state of suppressed excitement. *N. maximus*, *N. poeticus angustifolius* and *ornatus* opened their first flowers to-day (April 26); *bicolor Nelsoni major* and *Nelsoni pulchellus* are not yet opened; *N. Horsfieldi*, *N. Emperor*, *Backhouse's Emperor* and *N. sulphureus* are in flower at the present time. There is this consolation: if we have not the pleasure of seeing them so early in this part of the country as in some others, we have them with us when they are over in more favoured localities. I send five flowers of the Aldborough Seedling *Anemone* that I had from the late Mr. Nelson's collection; they vary somewhat; one has a white ring like *stellata*, which I had not noticed in the bed of original seedlings at Aldborough. Through the liberality of Captain Nelson in giving me a nice bit of fluffly seed last year I have a splendid batch of seedlings for flowering another year. I hope some day to be able to cut them as freely as we do the other two old kinds of which I have enclosed flowers. The scarlet Mr. Barr named *A. stellata annulata*, the dark pink variety, I do not know; though an old plant, I believe it is but very little known. These two varieties have been established here in quantity many years, and I am told no flower can surpass them and few equal them for lasting in a cut state in a London house. Our borders in the kitchen garden filled with *Iris reticulata*, *Scillas*, *Anemone fulgens*, *Narcissi*, *Triteleia*, &c., half fills the flower box during the spring months, supplemented with *Maréchal Niel* and other Roses twice a week; than these nothing gives so much pleasure or satisfaction at this season.

WILLIAM ALLAN.

Ruscus androgynus.—Your notice of this plant last week induces me to show you a flowering leaf. It is too little grown and is hardy in some parts of England. At Bitton I saw it growing against a wall, and from Mr. Ellacombe I got my plant about seven years ago. It is now 15 feet high and 3 feet through, a pyramid of perpetual rich glossy green. I grow it in a 22-inch pot in a conservatory. Another recommendation for its cultivation is that no insect seems to touch it, and so persistent is the foliage, some of which is 2 feet long, that several of the leaves are still fresh that

were on the plant when I received it from Bitton. It seems to enjoy about the same amount of shade as a *Lapageria* growing by its side.—J. M., *Char-mouth, Dorset*.

PLANTS IN FLOWER.

CLIANTHUS DAMPIERI.—We have received from Mr. Niel McDougall, Ormiston, near Edinburgh, spikes of this showy *Clianthus*, each bearing five and six flowers. The plant, a seedling, is stated to be 4 feet high and still growing fast. It is planted out in a house in which Melons used to be grown. The jet black boss with which each flower is furnished gives this species a distinct and striking appearance.

BUNCHES OF PRIMROSES of all colours—orange, pale yellow, pink, crimson, white with yellow eye and striped red—come to us from Mr. Caudwell, of Wantage, where these charming spring flowers have long been grown and well, as the size of the blooms and foliage sent testifies. Coloured Primroses are now becoming plentiful everywhere, but not more so than they well deserve to be. We should like to see them in our woods and copses as well as in gardens.

CLIANTHUS PUNICEUS.—Wreaths of this good old plant, sent to us from Mr. C. R. Scrase-Dickins, of Coolhurst, show how superior for general cultivation it is to the more tender of the same family, even though it has smaller flowers individually. A shoot nearly a yard long, with many rich clusters of flowers hanging from it, and good also in its graceful leaves, is a notable thing from a gardening point of view; but the charms of our own spring flowers are now so great, that few tropical things can compare with them.

BEAUTIFUL ROSES.—Owing to their large and abundant foliage, some Tea Roses from Gunton seem to possess a rare beauty. The flower commands so much admiration, that the delicate beauty of the foliage of Roses is said little about. These long and massive buds of Tea Roses are much more admirable by reason of the rich and graceful foliage in which they are half buried. Perhaps the noblest use to which our often stiff and bare houses can be put is the growth of these precious Tea Roses which our climate is too severe for in winter. It is not difficult to create a little Madeira or California for them in which given previous good culture they will bloom kindly for us.

ALPINE AURICULAS.—Dr. W. H. Browne, The Laurels, Aldborough, Hull, sends us trusses of three handsome alpine Auriculas, named *Star of India*, *J. C. Niven* (both laced sorts), and *Maud Browne*, a deep mulberry with a conspicuous yellow eye, and the handsomest by far of the three. Of this some of the flowers measured 1½ inches in diameter. A taste for showy and hardy Auriculas of this class has now set in, and is sure to march onwards. It is not everyone who can afford to cultivate the show kinds, but the alpine are within the reach of all, though they are all the better for the assistance of a cold frame in winter.

EUCHARIS SANDER, now in flower at Kew, is finer than we have hitherto seen it. The flowers are larger than we have seen them before, and, moreover, not so funnel shaped, but flatter and more spreading. They are 2½ inches across, with broad segments of firm texture and of snowy whiteness; indeed, there is nothing to mar the chaste purity of the bloom save a few faint streaks of pale yellow in the interior of the tube. The foliage is bold and handsome, quite different from that of either the other two species of *Eucharis*, and more resembling that of *Euryclis australasica*; it is broadly heart-shaped, pale green, and the upper surface is traversed by distinct furrows. It is seemingly a free grower and flowerer, and will doubtless become as popular as either of the other species of *Eucharis*, particularly for furnishing cut blooms.

MAGNOLIA SOULANGEANA NIGRA.—This is unquestionably one of the noblest and handsomest flowered hardy trees we have in gardens at the present day. It differs from the older and better known *M. Soulangeana* in having larger flowers of

a much deeper colour, being of an intensely deep maroon-purple, in fact almost black, on the exterior of the petals, but lighter within. It flowers a little in advance of the leaves, which are sufficiently unfolded to lend their tender green to harmonise with the richly coloured blossoms. This *Magnolia* is now in great beauty in Messrs. Veitch's nursery at Coombe Wood, whence we have received some admirable specimens of it.

FORTUNE'S YELLOW ROSE.—I am sitting with the first blossom of Fortune's yellow China before me, the loveliest thing I know, but instead of yellow it is all colours—pink, blush, buff, all blended together.—W.

BORONIA ELATIOR.—A very pretty bright New Holland plant, with many cheery rosy purple flowers and buds and cut leaves, somewhat resembling the Water Violet (*Hottonia*). It comes very well grown from the gardens at Nash Court, Faversham, and is one of the plants that make us wish for a revival of the once active fancy for New Holland shrubs. It is at home in the cool greenhouse.

FABIANA IMBRICATA, a neat Heath-like shrub from Chili, is sent us by Mr. Rogers, from Nash Court, Faversham. It is slender in growth; the long, spindling shoots are covered at this season with tubular white blossoms. It is almost hardy in this country, and quite so in Ireland, and in the warmer south counties, such as Devon and Cornwall. About London it succeeds admirably against a sunny wall. It belongs to the *Solanum* family, but is very unlike other members of the order, at least those in cultivation.

A NEW SEEDLING RHODODENDRON from Messrs. Lucombe, Pince & Co.'s nursery, Exeter, is a lovely variety. It is of the greenhouse section, and reminds one of *R. fragrantissimum*, but there is a delicate suffusion of pink in the flowers which renders them very beautiful. The blossoms measure 4 inches across the outspread petals, and are of good form and substance. The leaves are rather small, oblanceolate, glaucous, and scaly beneath, and ciliated at the edges, but glabrous on the upper surface. It appears to us to be a good addition to the list of tender *Rhododendrons*.

STOCKS AND WALLFLOWERS.—I send you flowers of the white Cape Stock, which gives 80 per cent. of doubles. It would make a fine kind for pots for conservatory decoration. The double yellow Wallflower is the dwarf branching kind, and shows how inferior it is to singles as regards effect. The single yellow Wallflower is sent to show how much inferior is the kind in common cultivation to Mr. Graham's Cranford Beauty. It is to be regretted that market growers confine their attention wholly to the dark red kind, as such a grand yellow as this would be purchased freely enough by the public.—A. D.

EDWARDSIA GRANDIFLORA.—This old-fashioned bush grows rather slowly in most parts of the country, but Mr. Scrase-Dickins sends us a beautiful branch of it from Horsham. Its curious and finely-coloured yellow pea blooms held in little brownish cups have a distinct beauty. If it could be grown and flowered freely, it would be very useful as an early flowering shrub. We do not learn from Mr. Scrase-Dickins how it is grown, but assume that it is out of doors. If so, what grows on the Horsham clay would grow easily on many better soils. When the flowers are looked at from above, there is a beautiful harmony of colour between the green-yellow of the flower and the green-brown of its cup. Usually it does well as a wall shrub.

EXOCHORDA GRANDIFLORA.—Trained against a sunny wall in the herbaceous ground at Kew, a bush of this beautiful shrub at the present time is bearing long wreaths of lovely snow-white blossoms. Though against a wall here, this shrub is perfectly hardy, and forms a neat, spreading bush if planted in good soil in an open position. When unprotected, however, by a wall it does not flower so early, and the blossoms are more at the mercy of the weather, wet and wind soon ruining them. We could not name a lovelier open-air shrub than this for spring flowering; but, beautiful as it is,

it does not appear to be much known. One good bush of it is worth more than a dozen of the second and third-rate flowering shrubs that are often crammed into shrubberies. A coloured figure of it appeared in *THE GARDEN*, Vol. XI., p. 152. It is nearly related to the *Spirea*, and is a native of North China.

HARDY SHRUBS in flower from Mr. Stevens' garden at Grasmere, Byfleet, include such handsome kinds as *Pyrus floribunda*, some long sprays of which are profusely laden with coral-red buds and flowers. *P. Maulei*, with branches laden with bright orange-red blossoms, is also highly attractive; likewise the yellow-flowered Currant (*Ribes aureum*), which thrives to perfection in the light soil at Byfleet; *Forsythia suspensa*, one of the showiest of spring shrubs; *Rubus spectabilis*, and *Menziesia empetrioides*, with flowers like those of the Irish Heaths, but with narrow, Yew-like foliage.

Berberis stenophylla, at present one of the finest plants in the open-air garden, is brought to us in grand condition by Mr. Stevens from Byfleet, and Messrs. Veitch from Coombe Wood. One of the specimens measures just a yard in length, and the entire shoot is a dense wreath of golden blossoms. A large bush of this Barberry with flower-laden slender shoots falling over on all sides might in truth be likened to a fountain of gold. *B. stenophylla* is a hybrid between *B. empetrifolia* and the beautiful *B. Darwini*, of both of which Mr. Stevens brings us excellent flowering sprays. Without these beautiful Barberries, a garden in May would be deprived of half its charm.

TULIPA KOLPAKOWSKYANA.—A flower of this new Tulip comes to us from Mr. Stevens, Grasmere, Byfleet. It is of medium size compared with ordinary Tulips. The flower segments, which are brilliant vermilion, are narrow and pointed. At the base of each division is a conspicuous black blotch; the anthers are also black, while the filaments are brown. Flowers of the bright yellow *T. sylvestris*, our indigenous species, are also brought by Mr. Stevens; likewise several other interesting hardy plants, including the pretty *Viola Munbyana*, with showy flowers of a bright violet-purple. It appears to be quite hardy at Byfleet.

PHLEDRANASSA CHLORACEA.—Of this extremely handsome and rare bulbous plant there is now a fine flowering specimen in the Royal Exotic Nursery, Chelsea. It has large globular bulbs, which produce long and broad deep green foliage. The flower-stems are stout and erect, and rise from 2 feet to 3 feet high, each surmounted by an umbel of from six to a dozen flowers, which, being large and supported by slender stalks, droop gracefully. They are tubular and nearly 3 inches long, the colour a brilliant crimson tipped at both ends with a deep pea-green—a singular combination. The plant is a free grower in a greenhouse temperature such as that of an intermediate Orchid house, and it is of easy culture if care is taken to rest the bulbs after they have perfected their growth. It is a native of the Andes of Peru. A coloured plate of it appeared in *THE GARDEN*, Vol. XVI., p. 286.

SPRING FLOWERS at Hoole House, Chester.—The rockery at this place, the residence of the late Mrs. Hamilton, is now gay with *Aubrietias*, which are really charming, dense clusters of them being covered with hundreds of flowers, clasping the rugged stones in a way not easily forgotten. The *Forget-me-nots*, too, are very fine, and so are the alpine *Auriculas*, which seem quite at home on ledges of the rock. *Primulas* of many kinds are also flowering finely, and noticeable in the collection was one called Arthur Potts, a beautiful rosy pink variety of great substance. *Phlox frondosa*, *Nelsoni*, *subulata*, *setacea*, *atro-purpurea*, *The Bride*, *compacta*, and *Perfection* are also in bloom. *Gentiana acaulis* and the beautiful little *G. verna* seem quite at home in a little shady nook. Of *Anemones* there are several—*fulgens*, *apennina*, *memorosa* and its double variety, *Robinsoniana*, and the *Pasque Flower* (*A. Pulsatilla*). *Saxifraga muscoides* and *muscoides atro-purpurea*, the beautiful

S. Wallacei, *Rhei*, *laevis*, *caerpitosa*, *hypnoides*, *Rochelliana*, and *cordifolia* are at present very interesting. *Iberis corifolia* and *sempervirens* are represented in grand style, and that beautiful little gem, *Arenaria balearica*, clings to the stones and flowers profusely. *Epigaea repens*, with its beautiful Hawthorn-scented blossoms, *Daphne Cneorum*, *Scilla campanulata*, *Epimedium alpinum*, *Arabis albida* and *bellidifolia*, *Ranunculus montanus* and *amplexicaulis*, and *Viola palmaensis* are all finely in blossom. A grand piece of *Anthyllis montana*, a yard through, is covered with half-expanded blooms, and promises to be a fine sight at no distant date. *Caltha parnassifolia*, a valuable subject for a rock garden, is bearing rich yellow blossoms in profusion. Several *Narcissi*, too, are in flower, amongst them being *Emperor*, *Empress*, *bicolor*, *Horsfieldi*, *ornatus*, and *incomparabilis*; also various others, the names of which would occupy too much room.—JAMES FINDLOW, *Botanic Gardens, Manchester*.

RHODODENDRON GLOXINIEFLORUM.—We have in the grounds here a large plant 9 feet high and 8 feet in diameter of this beautiful *Rhododendron*. It is a great acquisition, being one of the hardiest and freest flowering grown, and when in bloom is a glorious sight, proving far hardier than any of the Nobleman race, buds and flowers of which were completely destroyed, while not a bud of this one was injured. We have a good collection here, but I consider this the most valuable of all, and I would advise all lovers of *Rhododendrons* to procure it.—JOHN D. NANSCAWEN, *Whiteway*. [Truly a lovely *Rhododendron*, with large thimble-shaped blossoms of transparent waxy texture, profusely spotted inside with purple. The truss is large and dense, and the foliage rusty brown on the under surface. It seems to be an uncommon kind.]

WALLFLOWER CRANFORD BEAUTY.—Of this new Wallflower, Mr. Graham, the raiser, brings us a beautiful gathering which shows admirably what an extremely fine sort it is—the finest single yellow-flowered variety we have seen. Its blossoms are unusually large, and their colour a clear rich yellow. The perfume, too, is delicious. Mr. Graham remarks that an acre of this Wallflower in his grounds at Cranford, near Hounslow, is one of the finest sights imaginable. For comparison Mr. Graham brings a bunch of a sort raised by his late father and called Graham's Yellow Perfection, from which the present novelty has descended. It, too, is a fine sort, but the flowers are not so large as those of the new kind, and the colour is rather deeper. This was awarded a first-class certificate twenty years ago by the Royal Horticultural Society. For the spring garden and for cutting from this new Wallflower is a great gain.

BARBACENIA PURPUREA.—This remarkably distinct and handsome plant is quite out of the ordinary run of stove plants, and one, moreover, that is seldom seen in flower, but a few days since it was in bloom in the T range at Kew. It belongs to the family *Hamendoraceae*, and the genus contains but a few species, all natives of South America, but chiefly Brazil. *B. purpurea* is a herbaceous perennial, having long narrow leaves beset at the margins with fine spinules. The foliage is borne in dense tufts at the apex of the stem. This character, together with that of being recurved, reminds one at once of some of the smaller growing species of *Pandanus*. The flower-stems produced from the middle of the tufts are tall, slender, nearly erect, and considerably overtop the foliage. Each stem bears a solitary tubular flower, measuring about 2 inches across the six outspread segments. The colour, a rich velvety purple blended with maroon, is very beautiful and uncommon even among flowers. The plant appears to be free in growth under conditions of treatment that suit other plants which delight in a warm and moist atmosphere.

PRIMROSES FROM BEDFORD.—Some of these from Mr. Dean are very varied in colour and show a wide range. From what we have lately seen we believe there is a great deal to be done with our common *Primroses* and *Polyanthuses*. There are too many of the merely streaky and hard colours, and too few of the good velvety colours.

The point is to select colours that are good in quality throughout, and therefore likely to give a fine effect in group or mass. It would be impossible to limit what is wanted in the way of colour, because colours may be good in any degree—decided colours, or quiet and neutral ones. Mr. Dean has made a speciality of these flowers, and we hope that he will go on increasing his collection. The fringed varieties lately sent out are a distinct addition. The least valuable in colour are the variegated forms. To fairly judge the values of colours each kind must be seen in groups or masses in the open air—the right place for any of our native Primroses. They might be well shown in wide wicker baskets or in boxes, each kind apart.

AMERICAN ALOES IN FLOWER.—Two remarkable specimens of these interesting plants have arrived at their flowering stage in the Oxford Botanic Garden. They have been removed from their winter quarters in the large house devoted to the cultivation of succulents to an adjacent lawn, where they have been provided with temporary protection from unpropitious weather. As in the process of flowering these Aloes entirely exhaust their vitality, it will be seen that two notable specimens will soon be lost to the collection, which is one of the most complete in this country, and includes many exceedingly rare species. The largest is a splendid plant, with leaves striped with yellow, some of them being more than 6 feet long, from which rises a healthy flower-spike measuring no less than 10 feet in height, and which promises to be an exceedingly fine one when fully developed. The other, producing leaves which are not variegated, bears a flower-spike but little less gigantic. Their respective ages, we believe, cannot be determined with certainty, but it may be assumed that they have entered their traditional five-score years.

CYDONIA JAPONICA.—Of this well-known hardy shrub, Messrs. Veitch send us from their Coombe Wood Nursery some new and strikingly beautiful varieties. One named *atropurpurea* has flowers of the richest crimson imaginable, many shades deeper than the colour of the ordinary kind. Another, called *coccinea*, is of a glowing cherry red, distinct from any other and a most pleasing colour. Then there is the snow white flowered *nivalis*, which differs from the old white variety in its flowers being without the faintest suggestion of colour. A variety, too, without a name, is of a delicate pink like that of Apple blossom. These are most valuable additions to hardy shrubs and if properly placed would have a fine effect. Like most other flowering shrubs, the Japanese Quince abhors being crammed into a crowded shrubbery, as it too often is. A group of these beautifully coloured varieties placed in an open position on a lawn or on a sloping bank, with a background of some evergreen foliage such as that of *Mahonia*, would form at this season an uncommonly pretty picture. One would hardly imagine that so much diversity in colour existed in the old-fashioned Japanese Quince.

Bramley's Seedling Apple.—Canon Hole has kindly sent us a good many specimens of this very noble and, he says, hardy and fertile Apple. If such handsome Apples can be grown in Nottinghamshire, why should we go to Connecticut for worse? At this season this Apple has lost some of its flavour and juice, as most of our Apples do. The great want in our market seems to be a good supply of Apples in the spring. Whether by totally changing our ways of keeping Apples by storing them in cellars, or somewhere where they would not be dried up, in a warm or dry shed, we could improve our supply is a question worth considering. But why should we not try to raise a race of Apples, crossed with some of the later kinds, which would come in in spring? It is not enough that an Apple should merely retain its shape; we want its flavour, and this in March and April. It is a bad sign of our land system when we have to search the world for the Apples for which there is always so great a demand in our large towns; and even with all our importations

it is frequently difficult to get good Apples at a reasonable rate at this season of the year.

FERNS.

BEST CULTIVATED FERNS.

(Continued from p. 380.)

CYRTOMIUM.—This small genus only comprises three species, which are amongst the most useful for decoration, on account of their rapid growth and their firm texture, besides being all three very distinct and particularly handsome in appearance. They are, indeed, the best Ferns to be used in the least favoured places—in rooms and staircases, where their leathery foliage seems to defy the deadly influences of draughts, smoke, and even gas better than that of any other Ferns with which we are acquainted. Their bold foliage makes a striking contrast with that of finer-cut species when planted out in the cool fernery, in which place and under which treatment they will develop themselves into handsome specimens in an incredibly short space of time, and show themselves off to great advantage. For that purpose especially they are all three of the greatest value, as by the use of them we are enabled to give additional charm to the rockery not heated artificially, but simply covered with glass, where they, being evergreen, retain their beauty during the whole of the winter months. Their culture is very simple and their requirements very limited. The soil which suits them best is a compost of about equal parts of loam, peat, and silver sand, but care should be taken that they are not potted hard, or, if planted out in the fernery, that the soil round them should be kept moderately loose. They require a good supply of water at the roots during the growing season, and frequent syringings are beneficial to them during that time, but they should be watered sparingly during the winter months. It must be borne in mind that, although given to thrips, they will not get infested with them if not grown in heat.

C. ANOMOPHYLLUM.—This Japanese species is thoroughly distinct from the other *Cyrtomiums*. The fronds, which are produced in greater quantities than by any of the others, are from 1 foot to 2 feet long and pinnate, with numerous pinnae falcate-lanceolate, slightly auriculate, and about 2½ inches long, rather thin in texture, and of a dull dark green colour when matured, but prettily mottled with paler green in their young stage. It is of a close, compact, and rather erect habit.

C. FALCATUM.—This highly ornamental species, like the preceding one, comes also from Japan, and is the hardiest of the genus, as it has been found to stand out of doors uninjured in several parts of England, Ireland, and Wales, in which cases, however, it became deciduous. It produces a very stout, densely scaly crown, from which its beautiful fronds rise to the height of 2 feet to 3 feet; they are pinnate, with pinnae elliptic-lanceolate in shape, about 6 inches long and 2 inches wide. On account of its extreme hardiness, of its easy management, and probably also of the very rich dark glossy green of the whole plant, it is the species most commonly found in cultivation. Its habit, although not loose, is not so compact as that of the preceding species.

C. FORTUNEI (C. caryotidium).—Although a native of the East Indies, this species is just as hardy as the other two already described, and from which it is totally distinct, first by its drooping habit and also by the colour of the fronds, which, instead of being of a dark green colour, are of a most conspicuous light green tint. They are also produced from a thick, fleshy crown and pinnate, with pinnae strongly auriculate at the base, and much larger than those of the other two species. It is quite different from any other Fern in cultivation, and requires but very little care in its management.

CYSTOPTERIS.—Although this genus contains numerous species and varieties of British origin, there are but few exotic kinds in cultivation. Like our native ones, the exotic forms are all decidu-

ous and perfectly hardy under a glass structure, not requiring any artificial heat at any time. They are of very graceful habit, and their delicately cut fronds, gracefully arching over, make them charming ornaments for the hardy rockery, where they should be planted in rather stiff soil, and in such spots that no water should be allowed to rest on their crowns during the resting season. It is also advisable to avoid wetting their tender and brittle fronds at any time.

C. BULBIFERA.—This essentially North American species, of a very striking habit, produces fronds about one foot long when mature, herbaceous and rather thin in texture. They are about 5 inches or 6 inches wide at their base, and grow gradually narrower towards their extremity, so that they have a narrower and more tapering outline than any other Fern with compound and feathery fronds. The stalks are slender, about 8 inches long, smooth, and rather brittle, usually of a green colour except at the very base, where they are dark brown; they are rounded at the back, and have a deep, though narrow, furrow in front; the pinnae are oblong, obtuse, and more or less toothed. It is extremely peculiar on account of the formation of little bulbs which are found on the underside of the frond, mostly at the base of the pinna, but they often occur in various positions. They consist of from two to four rough, fleshy, greenish or deep-coloured masses, which contain one or two rudimentary fronds. These bulbils, falling to the ground, soon emit a few slender rootlets, and send up some little fronds. The next season they reproduce the parent plant with all its characters. Greenhouse.

C. FRAGILIS.—A thoroughly cosmopolitan species found in habitats very far apart, and having, according to its native places, characters almost sufficiently distinct to make different varieties of them. For instance, the *C. fragilis* commonly found in North America produces fronds averaging about 6 inches or 8 inches in length, whereas the fronds of those found in the Hawaiian and Canary Islands, as well as in the south of Mexico, are generally over 1 foot long, while the representative of that interesting species found in England produces fronds about 5 inches long; but it must also be borne in mind that this species is extremely liable to alter its forms according to the temperature of the season and the moisture of the situation. But apart from the various sizes and the little variations in the cut of the pinnae, it may be said to produce its fronds in dense clusters; these are supported on slender brittle stalks about 6 inches long, of a dark colour at the base, while the rest of the stalk, as well as the whole of the frond, is of a light green; they are generally of an ovate lanceolate shape, commonly a little narrower at the base than at the second or third pair of pinnae. These have a narrowly-winged midrib, so that while the frond appears bipinnate it really is only pinnate. Among the numerous forms that this species has produced only a few remain constant under cultivation. The two most distinct in characters are *C. fragilis laciniata*, with the segments of pinnae varying much in shape and more still in cutting; they are deeply and irregularly lacinate, the fronds at the same time being narrower in all their parts; and *C. fragilis tenuis*, a most elegant little plant with bipinnate, ovate lanceolate fronds of a dark green colour, and on that point at least differing very much from the species. This variety rarely grows more than 6 inches high. Greenhouse.

DAVALIA.—This extensive and well-known genus is composed of favourite species of great interest, all rivalling each other in usefulness and elegance, but varying essentially in forms and habits. They may be divided in two very distinct classes, the most conspicuous and most admired sorts forming a much appreciated group, popularly and deservedly known as Hare's-foot Fern (*D. canariense*), Squirrel's-foot Fern (*D. bullata*), Bear's-foot Fern (*D. Tyermanni*), &c., all denominative names given to these interesting species in allusion to the brown, grey, or silvery rhizomes with which they are provided, and which to a great extent

resemble, when destitute of foliage, the feet of the animals to which they owe their popular names. The second section contains only a few species equally beautiful and quite as ornamental, although deprived of the rhizomes, which in the former section are a constant source of attraction. *Davallias* have been found widely distributed, for although the majority of the species known at present come from the East Indies and the numerous islands of the Malay Archipelago, some, however, are from Australia and New Zealand, while in the south of Europe, Madeira, the Canaries, and adjacent islands is found the most popular species of all, the *D. canariense*. In consequence of their being scattered in such a large area and being found in such totally different habitats many beautiful forms can be made to decorate either the cool or the tropical fernery. Many of them may be used with great advantage as basket plants, where they make charming objects, especially those species with slender and flexuose rhizomes, such as *D. bullata*, *canariense*, *dissecta*, *pentaphylla*, and *Tyermanni*, whose habit it is to twine round and cover anything on which they are allowed to grow. If not grown in baskets or on blocks of peat, those with rhizomes, when potted, require to be a little elevated above the rim of the pot, as nothing is more injurious to them than to have their rhizomes buried in the soil, especially the species whose rhizomes are clothed with chaffy scales. Besides being highly decorative as specimens, their fronds possess another equally desirable quality, that of lasting a very long time when severed from the plant, which renders them very useful for bouquet-making and most valuable for the decoration of ladies' hair. Most of them are averse to heavy or close soil, and delight in a compost of light materials made of three parts of fibrous peat, one part of chopped Moss, or, better still, of good leaf-mould if procurable, and one part of silver sand, with thorough drainage and an abundant supply of water at the roots during the growing season, while they must be watered only sparingly during the winter, never allowing them, however, even those that are deciduous, to become quite dry. This is a very important point, as if their rhizomes are allowed to shrivel the ensuing growth will be much weaker. They require no syringing overhead to be grown in perfection, but will derive great benefit by being kept near the glass, where good light is obtainable.

D. ALPINA.—A charming little species of trailing dwarf habit, entirely distinct from any other kind. Its fronds, which are produced freely from very slender, flattened rhizomes, scaly at their points, are nearly triangular in shape when barren, tri-pinnate, coriaceous, and of a dark shining green. The fertile fronds perfectly triangular in outline, also tri-pinnate, are much more finely cut, and give the plant a very elegant appearance; they rarely exceed 5 inches in length, and last a very long time on the plant. This species, a native of Borneo, to be grown in perfection requires a very warm temperature and moist atmosphere, although it is not partial to watering overhead. Stove.

D. ACULEATA.—This very handsome species from the West Indies is particularly remarkable on account of its climbing habit, its elegantly divided fronds possessing the singular property of lengthening at the points very much in the way of the *Gleichenias*. They grow to an indefinite length; the stalks, rachis, and, indeed, the entire under surface of the fronds are covered with numerous short sharp thorns of a hook shape. The numerous pinnæ are cuneate in shape and bright green in colour. The plant is rendered still more attractive by the slender stalks and the fresh growths being of a pale claret hue. This species is devoid of rhizomes, all the fronds starting from a central crown, and makes a beautiful pot specimen; it may also be used with great advantage for covering a rustic pillar or for climbing over some rockwork, and should be either planted or potted in a more sandy or gritty compost than most *Davallias* generally are. Stove.

D. BULLATA.—A very pretty, small-growing, deciduous species from the East Indies, commonly

known as the Squirrel's-foot Fern from the general appearance of the creeping rhizomes, which are covered with minute scales of a reddish brown colour. The fronds, which are very abundantly produced on these rhizomes, are tri-pinnate, nearly triangular in shape, and of a rich, shining green; they seldom exceed 10 inches or 12 inches in length. It is one of the most useful kinds in cultivation, and makes a very fine specimen when grown in a shallow pan of good dimensions, where the rhizomes have plenty of room for extension. Stove.

D. CANARIENSIS.—Probably the best known of all *Davallias*, and commonly called the Hare's-foot Fern. The rhizomes are thicker than those of any other species belonging to the same genus, and produce magnificent triangular fronds of a bright green colour, and growing upwards of 2 feet high. It is a very ornamental plant either for basket, pot, or for planting out on rockwork. Being a native of the south of Europe, Madeira, the Canary Islands, &c., it does very well in a greenhouse.

D. DECORA.—A species from Java somewhat similar to *D. bullata*, but larger in all its parts. It is, besides, distinguished from that species by its growth being much stronger, its fronds averaging 1½ feet to 2 feet in length and 10 inches in width. They are produced on rhizomes, also quite different from those of *D. bullata* by the scales which cover them being larger and of a much lighter colour. Moreover, it is an evergreen species, and makes a splendid basket Fern. Stove.

D. ELEGANS.—This very grand species, a native of the Malay Islands, is no doubt one of the most charming of *Davallias*. Its rhizomes are stout, of a brownish colour, and produce a great abundance of tall, decomposedly, divided fronds of a rich, dark, glossy green colour, very useful for cutting, as they last a long time when off the plant if kept in water. It is very ornamental and of very vigorous growth, its beautiful fronds often attaining 3 feet in length. Stove.

D. ELEGANS VAR. *POLYDACTYLA*.—In its general aspect this garden variety resembles its typical form, and is as strikingly handsome as regards the dark glossy green of its substantial, long-enduring fronds; but instead of the extremity of the frond itself, as well as the extremities of the pinnæ and pinnales, terminating in a narrow point like those of the species, they become in the variety dilated and split down into several divisions, each of which is again divided several times, so that all the extremities are crested. It is very distinct and elegant, the whole contour of the plant being extremely ornamental. Stove.

D. FIJISIENSIS.—As its name implies, this charmingly elegant Fern comes from the Fiji Islands. It is up to the present the most finely divided of the *Davallias* in cultivation. The fronds, which although finely cut are firm and durable in texture, have a deltoid outline, and are of a bright green colour; they are, besides, gracefully deflexed and compoundly divided, the whole fronds being split up into lanceolate, almost linear, pinnales, and finally cut into narrow linear or bifid divisions. It is remarkably graceful in its whole contour, and being of free growth and of evergreen habit, it must rank amongst the most ornamental of the whole genus. This noble species has already produced two varieties worthy of cultivation—the *D. fijiensis plumosa*, with very elegantly pendulous and graceful fronds terminated at their extremities by a rich tassel, which still gives the plant a richer appearance; and the *D. fijiensis major*, also of a graceful habit. Although of much more robust growth than the species, this variety produces fronds equally as beautifully cut, although not so fine; they are borne on slender stalks, and of a much lighter colour than the two preceding kinds. It is very useful as a basket or pot plant, and very valuable for decorative purposes generally. All three species and varieties require stove temperature.

D. GRIFFITHIANA.—A very handsome species from Northern India, producing thick fleshy rhizomes covered with light grey scales, giving

their extremities quite a silvery appearance. These rhizomes produce some large, spreading triangular fronds of thick texture, which in a young state are of a charming metallic hue, turning later on to a pale glossy green. They are tri-pinnatifid, and their pinnules finely cut in proportion to the size of the fronds. Stove.

D. HEMIPTERA.—A very elegant, small-growing, and quite distinct species from Borneo, producing slender, creeping rhizomes, from which arise a quantity of pinnate fronds averaging about 8 inches in height, with pinnæ finely cut on the superior edge, and of a pale green colour. The general appearance of the plant is somewhat similar to that of certain *Lindsas*, but it is much easier to manage and of more vigorous growth. Stove.

D. MARIESI.—This very graceful Japanese Fern is of free growth and of very dwarf habit. As a basket Fern it is, no doubt, one of the best of the genus on account of its rhizomes being very slender, readily taking possession of the whole exterior surface of the basket and peeping out in all directions. In Japan it is even made use of in a very peculiar way. Some sticks being covered all over with Moss, some of its slender and very pliable rhizomes are tied to them and made into any form imaginable; they are then hung up in rooms or in the gardens under trees, and all they require then to produce their elegant fronds in profusion is a constant supply of moisture, which they get by occasional dipping in water; by these means an enduring globose mass of verdure can be made in a very short time. This pretty Fern is also very effective when grown in a pan in the greenhouse.

D. MARIESI CRISTATA is a very prettily crested garden variety of the above species, rendered more elegant still by the tasselled extremities of the fronds and of their pinnæ. It is extremely attractive when cultivated in a suspended basket, over which its flexuose rhizomes creep in every direction, as in that case the weight of the tassels helps to show to perfection the grace of its arching fronds. Greenhouse. PELLÆA.

LATTENBURY HILL HOUSE.

This place is chiefly notable for its pleasant situation, near the summit of the highest ground in Huntingdonshire, and for the collection of hardy trees which surround and shelter it, hiding it completely from the public road. There is not much of formal gardening, but there are plenty of cosy sheltered nooks for early bulbs and other choice flowers. There are several handsome specimens of the Cedar of Lebanon, one fine specimen overhanging the front entrance. Creepers adorn the walls everywhere, and bulbs and other early flowers grow close up beneath the windows. The view from the lawn across the adjoining valley, taking in the high ground in the distance, is very pretty, and this part of the county of Hunts being well timbered has a park-like character. Mr. Martin, the gardener, has occupied his present situation in the Sperling family more than 60 years, and most of the choice trees which adorn the grounds have grown up under his care. Singular to say, I had the pleasure of measuring a Cedar of Lebanon which girthed 10 feet 2 inches at 3 feet from the ground in the presence of the planter, Mr. Martin, who is now upwards of eighty, having planted it in 1820, or sixty-three years ago. I measured other Cedars planted about the year 1820 that girthed upwards of 8 feet, but the first one I named was the largest, and it stood in an open position in front of the house. It is sometimes stated that the Cedar is a slow-growing tree, but on good soil it is not so. The soil at Lattenbury is a heavy loam on clay, the clay coming up near the surface. There were also very handsome thriving specimens of *Wellingtonias*, *Taxodiums*, *Yucca Pinnata*, &c., as well as deciduous trees, including many specimens of Weeping Birch. One of the great charms of this little place is the repose, the peacefulness which the style of planting adopted seems to secure.

E. HOBDAV.

GARDEN DESTROYERS.

THE OAK LEAF ROLLER MOTIF.

(TORTRIX VIRIDANA.)

THE caterpillars of this pretty little moth are very destructive to the leaves of Oak trees, particularly in the south of England, and they occasionally occur in such extraordinary numbers that they entirely divest the trees of their foliage. When this is the case the trees suffer very much; in some seasons not only are a few trees here and there attacked, but acres, and indeed miles, of woodland are covered with swarms of this pest. Unfortunately, there is little or nothing that can be done to save large trees, particularly those growing in woods, from the attacks of these insects, but in the case of solitary or specimen trees much good may be done by spreading sheets on the ground under the trees and shaking the branches sharply, when the caterpillars will fall in great numbers. It is better to begin operations at the top of the trees, so that those which fall from thence and are caught by the lower branches may have another chance of being shaken to the ground. This insect is by no means very abundant every year, but, as is the case with many insects, for several years they may be positively scarce, and then for some reason, whether the absence of their natural enemies, or particularly favourable weather at a critical period of their existence, or some other circumstance is uncertain, they make their appearance in very great numbers for one or more seasons, and then suddenly disappear as mysteriously as they came, their disappearance being as difficult to account for as their arrival. Sometimes their very numbers prove the means of their extinction, as the foliage is all devoured before they are fully fed, and they die for want of nourishment. A high wind and heavy rain no doubt dislodge and kill many of them. The birds, as usual, help immensely in destroying these caterpillars. Rooks, jackdaws, starlings, thrushes, titmice, chaffinches, whitethroats, yellowhammers, the much-abused sparrows, and some others have been observed feeding on them, and are attracted to the infested trees by the prospect of abundant food. Pheasants feed on those which drop to the ground. The ichneumons and other parasitical flies attack them with great vigour, and on one occasion it was found that more than half the caterpillars were infested by some parasites.

The year before last I received a box full of caterpillars that were found feeding on the Oak leaves and stripping the trees; they were in such a state of decomposition when they reached me that it was impossible to say what they all were, but no doubt there were some of these Oak leaf roller caterpillars among them; in the box were also a number of hairworms (a species of Mermis, one of the Gordi), some of which were 7 inches in length and as thick as a piece of twine. As far as I could judge nearly every one of the caterpillars must have been infested with one of these worms, which had no doubt left their victims at their death. The only thing which we can do at present to diminish in any appreciable degree the numbers of this insect, considering how little we know of the circumstances which influence them beneficially or otherwise, is by encouraging as much as possible their enemies. In the case of birds this is easily done by not allowing their nests to be disturbed or the birds killed. Unfortunately, many persons still look upon birds of all kinds as destructive to the garden and farm crops; this is a great mistake, for birds do far more good than harm, and any crops which are liable to be injured by them can be protected by a little care and trouble. We know so little about the life history of the parasites of insects, that it is impossible to suggest any means for encouraging their increase except by not destroying them.

The moths appear towards the end of June, and lay their eggs on the twigs or buds; the caterpillars are hatched in the following spring when the young leaves are just appearing. They almost at once begin to roll up the leaves into a kind of

tube, which forms a protection for them against the weather and their various enemies. This would seem an almost impossible task when we consider the minute size of the caterpillars and the comparative stiffness of the leaves, and that each caterpillar works alone on a separate leaf. Many, if not all, caterpillars are provided with the means of spinning a silken thread, as silkworms do, being furnished with two internal tubes containing a thick gummy fluid (liquid silk, in fact); these two tubes are joined together, and terminate in one very fine one, which projects slightly from the head just below the mouth. When the insect wishes to form a thread it touches the object to which it is to be attached with the end of this tube and ejects a drop of the fluid, then drawing back its head or letting itself fall, a fine stream of this sticky fluid is drawn out, which immediately hardens into a strong thread. When the young caterpillar wishes to roll up a leaf, it attaches a thread to the underside of the edge of the leaf and fastens the other end to the

Oak leaf roller moth and caterpillar and rolled leaves.

leaf a little way from the edge. The thread in some way becomes tighter, causing the leaf to curl slightly. Some say the caterpillars tighten the thread by pressing it down and re-attaching it, or by pressing it down and spinning a fresh and tight thread which holds the leaf in a bent position. I am of opinion that the threads contract as they dry, and my own observations bear out my views. It is quite possible that both theories may be correct; the result is, however, the same. Subsequent threads attached in the same manner cause the leaf to curl more and more; others are then attached to the outside of this roll, which eventually presents the appearance of those shown in the figure. Within this shelter the caterpillar lives in comparative safety, feeding on the internal coils of the roll. If disturbed by the entrance of any enemy at one end of its dwelling it very quickly makes its exit at the other, letting itself fall, but still attached to the leaf by a thread, by which when it considers all danger is over it climbs up and regains its old quarters. When a branch infested by these caterpillars is shaken, large numbers may almost immediately be seen dangling at the end of their lines some feet in length. The caterpillars attain their full size about three weeks after they are hatched; they then become chrysalides within the curled-up leaves; in the course of about a

month the moths appear, and after pairing lay their eggs, as before mentioned.

The Oak leaf roller moth belongs to the family Tortricidæ, a family which contains several very destructive species, such as the codlin moth, the Plum tree Tortrix, and some smaller species, the parents of the grubs in Rose leaves. Members of the family may generally be recognised by the ends of the fore-wings which look as if they had been cut off straight. Tortrix viridana, so called from its beautiful green colour, measures nearly an inch across its wings when fully expanded; its head and thorax are of a pale green colour, its eyes dark brown, and its antennæ yellowish brown; the upper wings are the same colour as the thorax, except their front edges, which are whitish yellow; the lower wings and body are brownish grey. The caterpillars are about 5-8ths of an inch in length when full grown and are of a dull green colour with brownish spots; they are provided with a pair of legs on the first three, the sixth, seventh, eighth, ninth, and last six joints of the body. The chrysalis is of a very dark brown colour. G. S. S.

FLOWER GARDEN.

NEW AURICULAS.

THOSE who visited the National Auricula Society's exhibition at South Kensington on April 24, and who have been accustomed to visit such exhibitions during the last few years, could not have failed to observe how greatly the interest in Auriculas has increased since the first exhibition of them was held at the Crystal Palace, and more, what a great improvement has been made in them. Some look with contempt on the plodding florist; but from a rather extensive acquaintance with florists, I have no hesitation in saying that they get as much real enjoyment from their flowers as any botanist or practical horticulturist either. The Auricula exhibitions are the red-letter days in the florist's calendar. On those days they meet to compare notes, and to place their seedlings in comparison with those of others brought from distant parts, in order to show what progress has been made from one year to another. Five or six years ago certain varieties were exhibited in competing collections which would have no chance whatever to gain prizes now. The winning collections all contained seedlings raised during the last few years, and this, coupled with the fact that in 1881, and also in the present year, recently raised seedlings stood at the head of the prize list in a large competition, proves very conclusively that considerable progress has been made.

THE GREEN-EDGED class comprises very few really good flowers, and some of the growers are trying to improve it, and have had much success. Amongst varieties in commerce Prince of Greens (Trail) has the greatest merit, and is much esteemed by the fanciers. It has a handsome truss supported on a rather tall and stout stem, a fine green edge good ground colour, dense paste, but a pale tube, which dies off with an inky tinge. The old Col. Taylor (Lee's) is also very good as a green, and if it was as constant as Prince of Greens in producing good trusses, it would have to be placed before it. Nearly all the other greens have serious faults, which detract much from their other good qualities. Mr. Horner's new seedling named Monarch is very promising. Greenfinch, exhibited by Mr. Barlow, was not quite strong enough to show its qualities, but in the shape of a small plant it looked as if it would prove to be a good flower, the green edge and dark ground colour being regular and well defined. Lieut. Charrington, exhibited by me at Regent's Park, has a really good green edge, but the ground colour is faulty, although it has a good gold tube. There are other promising flowers in collections which will probably be exhibited on a future occasion.

THE GREY-EDGED CLASS, although not open to so much improvement as any of the others, may yet be added to with advantage. George Lightbody (Headley) is yet the best in commerce, and,

taking it altogether, it probably cannot be surpassed. Ajax (Horner) and Miss Lodge (Douglas), though considered the best at the recent national exhibition, are not equal to it in all points. Probably they are behind Mabel (Douglas), which gained the premium prize two years ago, and was awarded a certificate. It also gained a certificate from the Royal Botanic Society on April 25. Mrs. Moore (Douglas), figured recently in the *Florist*, has also had certificates from two societies. Silvia, by the same raiser, is a distinct and good flower, which is much thought of by the fancy.

THE WHITE-EDGED is also a class in which there is nearly as much room for improvement as in the green. John Simonite (Walker) is perhaps the best that has been sent out as yet; but Read's Acme is a neat, constant, and good variety. Heap's Smiling Beauty, long esteemed as the best of this class, is gradually falling into the background. Mr. Horner has raised some excellent varieties during the last few years. Godfrey Horner exhibited last year is a good flower. Mrs. Horner, Snowflake, and others may be heard of again. Conservative (Douglas), which has received two certificates from the principal societies, and gained the premium prize as the best Auricula in the exhibition on April 24, has many good qualities. Mr. Simonite's Frank, sent out very recently, is a free growing good flower of a pleasing bluish purple ground with a good white edge. In

SELFS, the new varieties are well in advance of the old ones. Pizarro (Campbell), which has several faults, is now left in the rear, but it has long held the highest position. Heroine (Horner) is the best self yet raised, and it was exhibited in grand form on the 24th; Kingdove (Horner) is the next to it, and is a beautiful variety; Duke of Albany (Douglas) is a fine dark flower, the edge of which contrasts well with the snowy white centre; Sapphire (Horner) is a distinct and good flower, rather rough, but worth growing for its beautiful bluish colour; Mrs. Douglas (Simonite) is thought to be a better flower, and is much of the same colour as Charles James Perry (Turner). Mr. Simonite has a good crimson seedling, a colour in which there is much room for improvement, as Lord of Lorne is rough and Duke of Argyle a shy grower.

THE ALPINE AURICULAS have been much improved since the first national exhibition was held in London. Mr. Turner, of Slough, has quite taken the lead in this section, and annually introduces many very fine seedlings. Perhaps no better type of an alpine Auricula was ever raised than the variety named Dr. Hogg. It has a beautiful shaded edge with a fine gold centre. Roysterer, E. S. Dodwell, E. R. Cutler, Mariner, Artist, &c., are great advances on the old self-edged kinds, which were grown and valued less than ten years ago. The alpine Auriculas are much easier grown than the show section; the flowers have no delicate farina or meal on the foliage to be marred by the least touch, and they are very interesting and beautiful when planted out in the flower borders or in the rock garden. J. DOUGLAS.

VICTORIA ANEMONES.

THE truly superb display of cut blooms of these so-called Victoria Anemones staged the other day at South Kensington by Messrs. Collins & Gabriel calls for more than a passing notice. It is doubtful whether visitors to South Kensington, or indeed to any other English show, have seen for many years past, if ever, such a show of coronaria varieties of Anemone in such fine form and superb colours. It says much for the enduring character of cut Anemone flowers that these should have travelled so well all the way from Cannes and opened so admirably without losing a petal. In your report of the show just alluded to it was said, "would that we could grow such Anemones in our English gardens." To that let me reply, so we can and do, only the blooms are not quite so large, but in all other respects they are quite as good in form and varied in colour. Let me impress upon the readers of THE GARDEN the fact that

although dry roots are cheap and safe, yet seed is much cheaper, and sown now under glass will yield for about 1s. 6d. spent several hundreds of strong plants next autumn, which if planted out in good garden soil will bloom superbly from November to the end of May. I looked carefully over the several hundreds of fine flowers shown by Messrs. Collins & Gabriel, and also over Mr. Cannell's smaller collection from the same source, but found none of those semi-double flowers which were plentiful thirty years ago. My own strain produces every year a few of the real double section, which consists of an outer row of guard petals, whilst the centre is a dense cluster of enlarged or petaloid stamens; but with these, though richly coloured, I am not greatly enraptured. The semi-doubles of old days gave two or three rows of petals, and resembled very much semi-double Peonies. I remember that in 1850 the gardener at Westwood Park, Southampton, had this semi-double strain, the flowers of which were remarkably fine and well varied in colour, but that garden has long since disappeared. I hope to be able to get this strain back again in time, because I have already noted in my own beds two or three flowers having twice the usual number of petals, and these may reproduce a strain of the desired flowers. I met with one, to me remarkable, novelty in my beds the other day, viz., a pure white flower having white stamens. Except that one I have never seen a bloom, let its colour be what it may, that had not a cluster of black stamens.

A. D.

BLUE SPRING FLOWERS.

It has often been remarked how rich the alpine flora is in plants of a blue colour, while in the lowlands it is rarely seen. Those who, even in a small way, endeavour to cultivate alpine plants can bear witness to this, especially in the early spring months. Both amongst bulbs and plants there are some of the most exquisite shades which can be imagined. In looking round my little plot I have been enabled to find the following:—

MUSCARI BOTRYOIDES.—The exquisite tint of deep sky-blue colour in this Grape Hyacinth is quite unique, and the plant itself most easily grown, either on the rockery or in the herbaceous border. There are several varieties or newly introduced kinds, but I do not think that there is anything superior to the old well-known inhabitant of our gardens.

ANEMONE APENNINA.—A group of this on a part of my small rockery is now one sheet of bloom; its star-like flowers, thickly placed on its low cushion of leaves, form a very pretty object. There is a variety of it of a silver greyish blue, which is also very pretty. It is another very easily cultivated plant, and ought to be generally grown. The same may be said of a flower very similar to this, Anemone blanda, which blooms earlier, coming into flower with the Cyclamen, and long before those flowers which we are in the habit of associating with earliest spring the Snowdrop and Crocus venture to make their appearance, and rapidly cover the ground, as does A. apennina, and the chief care is to prevent weeds growing in amongst the roots, especially the common Crows-foot, which at a distance bears some resemblance to its foliage.

GENTIANA VERNA.—Here, instead of easiness of culture, we have an exceedingly difficult one—at least it is so to the generality of cultivators—and is one of those cases which seem to point out the cause of difficulty. I have some plants of it on the rockery which are struggling for an existence, while a pan under glass is a mass of beauty; and what can surpass it? The cause, then, seems to be the excessive wetness of our autumn and winter months. During that time, in its natural habitat, it is covered thickly with snow and kept perfectly dry and warm; this is a condition we cannot emulate in our climate, and the changes of temperature to which it is exposed are injurious to its well-being. I had half-a-dozen fine plants of it from Froebel at Zurich in the autumn, and planted them with great care in suitable soil on my little rockery. They have become miserable-

looking, and I find that the slugs have a peculiar fancy for the flowers, which are no sooner formed than they are eaten. I have consequently to-day (April 21) lifted them from the open and planted them in a pan, and I have little doubt that after a time they will revive, but one grieves to find that after so many trials its out-of-door culture has to be abandoned. I hear of, and indeed now and then see, a tolerably successful attempt at its cultivation, but it is a difficult matter to accomplish, and many failures will take place before success is reached.

GENTIANA ACAULIS.—This, on the other hand, is as easy of cultivation as verna is difficult. I know one large garden in Kent which is completely bordered with it in broad masses 9 inches wide; and lovely it is in the spring months, with its thick dense foliage and its deep cobalt-blue flowers standing well up above the foliage. When the sun is shining on some good plants of this flower, nothing can exceed the loveliness of its colour. The idea that this is a difficult plant to grow has prevented many from growing it, but, except in very dry soils, no plant is easier to cultivate. I imagine that its closer, more rigid foliage enables it to resist the influence of wet, and hence it does not suffer from the winter as verna does. It is not so early to bloom as verna, rarely showing its brilliant flowers before May, and, just as I have seen Gentiana verna in lovely masses on the Col de Balme in the early part of June while it had long been past its best in the valleys, so with this and many other flowers; their situation greatly regulates their time of blooming. I think it well to say that more than once when I have ordered Gentiana verna this has been supplied to me instead, and when I was told once that a more robust form of verna had been discovered, I found on receiving it that it was my old friend the Gentianella.

SCILLA SIBIRICA.—A well-known, easily grown bulb, with flowers of a different shade of colour from any of the preceding; there is a metallic hue in it which is very distinct.

SCILLA BIFOLIA.—Another very pretty bulb. There are two varieties of it, one flowering very early, almost with the Cyclamens, and another somewhat later. Very easily grown, and most desirable. With the former of these (sibirica) I have experienced disappointment this year; I do not know from what cause, but I imagine from the depredations of slugs which eat off the shoots when they are just appearing above ground. By-the-by, I wish I could say with Professor Owen that these were a rarity; there is never a shot fired in my garden, and I have blackbirds (the thrushes have suffered from severe winters), but withal, the slugs have been and are a perfect pest, and of course the stones on a rockery form a delightful harbour for them; the slugs, too, seem especially fond of the blooms.

MYOSOTIS DISSITIFLORA.—Everyone knows and admires the Forget-me-not, and this seems to be the earliest flowering one. The charming little rupicola I cannot manage, and I fancy that in our garden soil it loses its dwarf character. It must be borne in mind that there is nothing which seeds more freely than the Forget-me-not, and that very soon the whole rockery will be covered by it if it is not closely watched; happily, it is very easily pulled up. In my small rockery it has overflowed the back of it, and is a mass of bloom. There it is quite at home and undisturbed, but I have to very carefully guard the front portion, or it would soon be nothing else.

OMPHALODES VERNA, or creeping Forget-me-not, as it is sometimes called, is an easily grown and rapidly spreading herbaceous plant. The flowers are, unfortunately, too scantily produced, but are of a very lovely shade of colour. This plant grows well in shade, and is valuable wherever it can be introduced, but, to my mind, can never equal the Forget-me-nots in value, for, while they are one sheet of flower, this only produces its flowers, as I have said, sparingly.

AUBRIETIAS.—Not strictly blue flowers these, but very nearly so, and their lovely purple blossoms are abundantly produced. A plant which I

had given to me some years ago by Mr. Ingram, of Belvoir, is, I think, the best that I have seen, and is now one sheet of lovely purple.

CHIONODOXA LUCILÆ.—This, the latest addition to our spring flowering bulbs, from the mountains of Smyrna, is, I think, the most lovely of all; true, the flowers have not the intense blue of the Gentians, but there is a loveliness in the cerulean tint of the petals, relieved by their white centre, which makes them unsurpassed. As it has only recently been introduced, it has hardly been seen in its real character. Some bulbs that I have had three years in the ground threw up long racemes of flower, seven or eight in number, so that when we get it fully established it will be a delightful addition to our gardens. It is the hardiest of the hardy; it was in flower in my garden when the intense frost and snow of the latter end of March came on it, and I thought it was done for; but it burst forth into fresh beauty, and, although a cold north-easter is not favourable for vegetation, yet it has bloomed bravely through it all.

Such are some of the vernal beauties of various shades of blue one may have, where alpine plants are loved and cultivated; there are doubtless many others, but these are what I have now under my eye, and which have given me real pleasure.

DELTA.

OUTDOOR HYACINTHS.

ALLOW me to corroborate all that Mr. Archer-Hind says about the quality of Hyacinth flowers from imported bulbs planted out in the open ground. It is a mistake to suppose that after the first year only very weakly flowers are produced, as with ordinary care good strong spikes will be thrown up every season. Even when the bulbs have been forced they will, if taken good care of, bloom tolerably the following year, although I think it preferable to give them a season of complete rest by picking off the flower-spikes as soon as they form. Of course no one can expect them to do other than dwindle if, after being used for decorative purposes, they are at once turned out of their pots and laid in the open ground, there to be at the mercy of the elements. If no frame room can be accorded them they should be sheltered in some way on cold nights and in inclement weather, and they should be kept well watered until the foliage decays. In this way they will go as naturally to rest as if growing in the open ground. Mr. Archer-Hind does not say if he bestows any special culture on his bulbs in the way of annually lifting and fresh planting in new soil, or whether they are allowed to remain undisturbed from year to year. Probably one reason for the common notion that imported Hyacinths rapidly deteriorate is that they are set out in impoverished soil and allowed to remain from year to year without nutriment of any kind being afforded them. The change from the highly manured bulb fields of the Dutch growers is so great as to alone account for any sudden loss of vigour. I should say that no crop grown has so much expended upon it for manure as Hyacinths, sometimes several hundred pounds' worth of cow manure being put into a single acre of ground. There is therefore no wonder if bulbs go back rapidly when deprived of this rich food; it would, indeed, be a matter for surprise if they did not. Even when planted out in beds of rich soil they often do not get a fair chance, as they are frequently lifted before the foliage begins to decay, in order to make room for the summer "bedders." Where the natural soil of a garden is good, and annually receives a coat of manure, Hyacinths will throw up strong spikes of bloom every year, and it is almost superfluous to say that the poorer the ground naturally the more need for its application. There is no actual need to take up the bulbs every year, as some stimulant may be applied in the form of a top-dressing.

J. CORNHILL.

Hesperochiron californicus is a very dwarf and pleasing perennial. Its flowers are white, slightly tinged with rose towards the edge, much resembling those of a *Convolvulus* in general appearance. Some have distinct dark purple honey

lines down the centre of the corolla lobes. The leaves are greyish green and hairy, and most of them paddle-shaped. From one crown will spring over a dozen flowers with as many leaves; the whole plant does not measure above 6 inches across nor its graceful flower-stem more than 3 inches high at most, while an expanded flower is $1\frac{1}{2}$ inches across at the tips, its tube being about half as long.—P. SEWELL, York.

DAFFODILS AND THE DRY SEASON.

IT is curious what a difference soil makes in dry seasons. My Daffodils are finer this dry spring than they ever were, Emperor and Empress especially, the latter this year quite surpassing Horsfieldi, though the latter is unusually fine. Ajax princeps, too, which Mr. Wolley Dod says does not succeed out of doors so well as Telamonus, is splendid here standing well out of the ground; on the contrary, in Mr. Brockbank's garden, which is sandy, they are not so fine as usual. I see a good deal of controversy about white Daffodils. Whether or not Mr. Wolley Dod is right in saying that they may all be reduced to varieties of two species, viz., *moschatus* major and minor, as figured in the Bot. Mag., the fact is perfectly well proved by my experience, year after year, that the variety usually called *cernuus*, and sold by Mr. Barr and others under that name, is much hardier than the *moschatus* or silver trumpet, grown extensively in Holland and imported thence. The former increases as quickly as any of the hardy yellow trumpet Daffodils, but *moschatus* dies out after a few years. *N. Bulbocodium*, too, only survives on a raised sheltered mound of peat soil grown with Heather and other peat plants which protect the young leaves.

Aigburth.

WHITE DAFFODILS.

THE more authorities we examine about these, the more puzzled we are sure to get. In the first place, who gave them their names? Mr. Burbidge in his monograph tells us that they were introduced from Spain about the year 1600. In those days everything foreign was said to come from Spain, and as I cannot prove that white Daffodils came from any other place, we will assume that this is true. Thirty years later, when Parkinson wrote, several varieties were in possession of names, which we will suppose to have been given by the botanists of the period from certain characters of the plants; let us see what their names mean.

1. **MOSCHATUS** (imbued with Musk).—The botanists of those days were rather fanciful, and perhaps one of these white Daffodils grew amongst that troublesome garden weed, *Mimulus moschatus*, for no recent writer pretends to have recognised the smell of Musk in any white Daffodil flower.

2. **ALBICANS** (inclining to white).—We may suppose this was given to one which had flowers seeming as if they were going to be white, but never becoming quite white. This is the character of more than one of the so-called white Daffodils.

3. **CERNUUS** (looking down).—All Daffodils do this when opening, but most of them raise themselves afterwards till the tube is nearly at right angles to the stalk, but two or three of the varieties of white-flowered Daffodil remain to the end with their noses to the ground. The most cernuous Daffodil I have come to me from Mr. Brockbank with the name *tortuosus*.

4. **TORTUOSUS** (twisty), probably referring to the perianth segments, though an accomplished gardener and botanist told me he had always taken it to refer to the green leaves. Those Daffodils which have these segments narrowest twist them most, but all the white-flowered twist them more or less.

The next thing to speak of is figures, and I will only mention those which are coloured—two in Curtis's *Botanical Magazine*, t. 924, representing *moschatus*, and t. 1300, representing *moschatus* d. or minor. These are the best figures of Daffodils I know, and all subsequent writers on the species have referred to them. The larger flower (t. 924) is identified with *tortuo-*

sus both by Herbert and Haworth (monograph of *Narcissineæ*, published as an appendix to vol. i., series 2, of Sweet's "Flower Garden."). Haworth calls t. 1300 (printed by error 1800) *moschatus*; Herbert calls it *candidissimus*. Sweet's figures, though more elaborately got up, have not the truth of character which Curtis's have. I speak by comparing those of well-known flowers. He figures two white Daffodils, series 2, t. 101, *N. cernuus*, double and single, and t. 145, *N. albicans*. Neither figure recalls unmistakably any form I know. In Burbidge we have *moschatus*, two good figures of the larger white Daffodil, and *cernuus*, double and single flowers of the more slender form. I have no doubt, by comparison of the above figures, that both names and kinds are in confusion.

A very few words on the natural history of white Daffodils. I am investigating this, and so far, am inclined to believe that they are all accidental seedlings from *N. Pseudo-Narcissus*. There is a meadow in Oxfordshire in which Daffodils with whitish flowers grow indiscriminately, mixed up with common wild Daffodils, showing no distinct character, except colour. A careful observer living in Devonshire sent me this year a flower which he felt sure was a seedling from *N. moschatus*, which has all the colour of *N. Pseudo-Narcissus*, and I have this day received a letter from a clergyman in Dorsetshire, from which I copy part: "I have little doubt that you are correct in believing that most of the Trumpet *Narcissi* are varieties of *N. Pseudo-Narcissus*. A few years ago I saved a seed-pod of *N. cernuus*, and obtained from it three plants; two of these on flowering could not be distinguished from the common *N. Pseudo-Narcissus*, and the other was like the parent, *cernuus*. This fact goes some way towards proving the case." If this is so, we can hardly expect the white varieties to exhibit more fixed characters than their parents, the wild Daffodils.

C. WOLLEY DOD.

SPANISH DAFFODILS IN WALES.

THE origin of the Spanish Daffodils, which have for a very long time grown wild in South Wales, has frequently been referred to in THE GARDEN, and only recently by Mr. Burbidge, who stated that the Flemings had probably been the means of introducing them. As, however, the Flemings settled in Gower as far back as the reign of Henry V., and as the Tenby Daffodil is not known to Mr. Llewellyn as being found wild in Gower, we must look for some other possible occurrence which may have led to its introduction. In a former note I alluded to a tradition I had heard about Orange trees which are now growing in South Wales, and which had been obtained by the shipwreck of a Spanish vessel. Mr. Llewellyn, of Penleare, tells me that this is so. They were brought from Spain as a present to William and Mary, and, being wrecked on the coast, were impounded by the Lord of the Manor, and are now at Margam in the possession of Mrs. Talbot. Mr. Llewellyn has also ascertained that there was a Spanish galleon wrecked off Gower, and that gold moidores of the date of about 1622 are frequently found upon the shore near the place at which the shipwreck happened. Here, then, we have two instances of the shipwreck of Spanish vessels in the neighbourhood of Carmarthen Bay. One may, therefore, reasonably suppose that some sailors or Spaniards had reached the shore, and possibly settled down in the country, as the Flemings had done, and thereby the possible introduction of the Spanish Daffodils may have resulted.

Mr. Llewellyn tells me further that other forms of Spanish Daffodils grow wild upon his estate near Swansea, and that Mr. Barr after seeing them wrote, "How came they into Wales? I should say they were Spanish or Portuguese, and if you can trace any connection between your estate and these countries either in commerce or family, you may account for your plants, which are close on *Narcissus* major, and very much like a form of *N. major* collected wild and sent to me from Oporto." Here, then, is another undoubted

form of Spanish Daffodil growing wild in South Wales in addition to *N. obvallaris* at Tenby. The subject is an interesting one.

Brockhurst, Didsbury. WM. BROCKBANK.

VARIETIES OF ANEMONE CORONARIA.

THESE are the very best flowers one can have at this season, as they yield an abundance of the brightest and showiest of blossoms, which last fresher and longer in water than any others with which I am acquainted. Here we have had them in plenty ever since Christmas, when we used them in a cut state along with Hellebores, a combination that was very effective, especially as regards the scarlets and blues of different shades, which show up in most pleasing contrast with the white of the Hellebores, and make one of the finest of displays. To get the Anemones in so early we took up plants with good balls and placed them in a frame where they could get a little bottom-heat from pipes running underneath, which kept them gently on the move; and as they were well up to the light, and had plenty of air, the flower-stems came short and stout, as they do in the open. The plants on the border from which those referred to were lifted have supplied us with blooms since, and are still gay, with lots open and coming. The seed was sown about this time last year, but, good as they are, I have no doubt they would have been still better if we had done as "A. D." has—sown early in heat and pricked the plants out, as then they would have been larger and stronger. As the time is passed for this now, I would advise all who wish to grow these fine Poppy-headed Anemones to prepare a border at once and sow them; but to meet with the fullest share of success, the position must be a sunny one, as warmth is absolutely necessary for their welfare, and they only expand their gay blossoms when the solar rays are upon them, except they are cut and placed in water in rooms, where the warmth causes them to unfold and keep open. They are therefore most valuable for cutting, as they last as long as they do on the plants. The soil most suitable for Anemones is that which is light and rich, and if not so naturally it should have a good dressing of leaf-mould and rotten manure dug in together with a sprinkling of sharp sand, which will keep it open and porous. The proper distance to sow the seed is to have drills about a foot apart, in which it can either be scattered thinly or dropped in patches 8 inches or so from each other, and when the plants come up they should be singled out.

S. D.

Androsace carnea, considered a difficult alpine, succeeds well in a perfectly level spot in the alpine garden in hard, well-drained sandy peat. It had grown fitfully and flowered sparingly for four years on rockwork, and has much improved since it was moved to level ground, and is now covered with flowers; flat flakes of stone laid round the necks of the plants just keep the foliage off the earth.—G. J., *Surrey*.

Primroses from seed.—What a wealth of variety can be obtained from a single packet of good seed! I counted upwards of fifty distinct varieties at Captain Bagwell's to-day near this town. There was every conceivable shade and marking, from the purest white to the deepest fiery red and brightest yellow, through rose, purple, magenta, pink, lavender, lilac, mauve, bluish, and so on; fringed, serrated, lacinated, rough, and even-edged; some large, small, and others diminutive. Even the foliage was essentially different. They had, however, one delight in common—they were all sweet scented. No wonder they have so many admirers, and that they are becoming so popular.—W. J. M., *Clonmel*.

The great Christmas Rose.—In a bed of Hellebores here there is a plant of *H. niger* maximus, the bloom buds of which were destroyed by mice in the autumn; consequently, the usual season's flowers were lost, but during the mild weather after Christmas it began to throw up more buds, and has bloomed almost continuously since,

and buds are still appearing. I forward a specimen cut to-day. This seems to point to a way of obtaining a long succession of flowers for those who have spare plants and desire it, but probably few would have the courage to sacrifice the first crop, coming as it does, so welcome in the dreary season. The illustrations and frequent articles in THE GARDEN on this beautiful and useful family have, no doubt, in no small degree contributed to their deservedly growing popularity.—J. M., *Charmouth, Dorset*.

MATERIALS FOR GARDEN WALLS.

THERE can be little doubt as to good bricks being the very best material with which to build a garden wall, and unless in exceptional instances, such as where suitable stone is to be found upon the spot, the most economical. Garden walls may, however, be built of stone and faced with brick, and if the materials are properly bonded together there need be no fear of their parting company. Garden walls, however, built entirely of brick with stone coping are undoubtedly the best, as in most gardens it is found to be expedient to use both sides of the wall for training purposes. Your correspondent (p. 365) proposes to build the north wall of the garden (that is, the wall on which the lean-to glass structures are to be erected) 12 feet or 13 feet high, and the remaining three walls 7 feet high. Now, unless the garden enclosed is very small, these heights are insufficient. If we suppose the garden enclosed to be three or four acres in extent, the walls should not be under 10 feet or 12 feet in height, and the wall against which the lean-to structures are to be placed might with advantage be at least 14 feet high. Such fruit trees as the Pear, Plum, and Cherry could hardly be fully developed upon walls not more than 7 feet high, and 14 feet would not be too high for the back wall of houses intended for the culture of Vines, Peaches, or Nectarines. Whether garden walls are built of brick or stone, or of a combination of both, they should have a sound and substantial foundation; that for a 14-inch wall should be several inches wider, and the work as it proceeds should be, as I have said, well bonded together by having the bricks laid lengthways across the work every other course or so. If this is done, few, if any, buttresses or supports will be necessary. A good coping can be formed of brickwork with a strong tile projection of 3 inches or 4 inches; but by far the best, and possibly the cheapest, is one of Arbroath stones. These can be had in lengths of from 3 feet to 6 feet of any desired width, and, being remarkably hard, resist anything like injury from inclemency of weather or other causes, and at the same time have an excellent appearance. This, or any other coping, should, of course, have a projection of 3 inches or 4 inches, and should also have a groove on the under side on each side of the wall at a distance of half an inch from the edge. This is of great importance, as it effectually throws off the water which would otherwise run down the face of the wall, and if it is intended to train fruit trees on each side of the wall (which is usually done) the coping should be laid level; but if it should be intended to train on the inside only, then it may with advantage be laid so as to give a slight fall to the outside.

In order, however, to make the most of garden walls, which under any circumstances are more or less expensive, it is usual to surround at least some portion of the garden with additional slips of land, which are found very useful for producing early and other crops of vegetables of various kinds, as well as allowing both sides of the walls to be used for tree training. This generally necessitates the use of a fence of some kind, such as a hedge of Holly or White Thorn. The former, however, is to be preferred, and the slips of ground so enclosed may be of any desired width, say 50 feet or 60 feet, thus forming a useful border for culinary crops, without rendering it necessary to crop too close to the roots of the trees on the walls. The too common practice of securing trees to walls by the use of nails and shreds is decidedly objectionable, and is very pro-

perly being discontinued, as it tends to seriously injure and disfigure the surface of the best built walls, whether of brick or of stone, and in the case of new walls it ought by all means to be avoided. Such walls should either have permanent studs fixed in them before the mortar becomes quite dry, or, what is possibly better, the walls when finished should be properly wired, so as to obviate the necessity of driving nails into them in the process of training the trees. Where it is decided to do this, a wall constructed entirely of stone with the surface of the same properly cemented may be little if at all inferior to a brick wall, as the surface of a cemented wall may, of course, be made to assume any desired shade of colour, so that the question resolves itself into one of appearance and of cost. Objections were at one time taken to wired walls, inasmuch as it was supposed that a current of cold air would be likely to be set up between the surface of the walls and the trees trained thereon, to the serious detriment of the latter. The conducting properties of the wire itself were also objected to, being in immediate contact with the shoots. There may perhaps have been grounds for such objections in cases where the wires were fixed at a distance of 1 inch, or even more, from the surface of the walls. But as now practised the wires are fixed as close as possible to the surface of the walls, so that the branches of the trained trees are as close to it as if secured by nail and shred, and no possible current of air can exist between them; the supposed conducting property of the galvanised wire is also neutralised by its contact with the non-conducting surface of the walls. At all events, it may now, I think, be said that the most successful cultivators of fruit are agreed in making no objection to properly wired garden walls. As regards the question of the most suitable aspect for the various kinds of fruit trees, it may be said that the Peach, Nectarine, Apricot, and Fig require and ought, if possible, to have a southern aspect; Plums and early Cherries will succeed on an east aspect, and a west aspect will be found suitable for most of the best Pears, or this latter arrangement might be to some extent reversed by having a portion of Plums upon a west and some Pear trees upon an east exposure, while a northern exposure is that best suited to the Morello Cherry, Red and White Currants, and for late Gooseberries, in order to prolong the season of these wholesome and delicious fruits.

I have even known some of our finest Plums, notably Coe's Golden Drop, to succeed admirably upon the north side of a high wall. Previous to the wiring of the walls, however, it is advisable to determine as to the kinds of fruit trees to be trained upon them—as, for example, the Pear, is usually trained horizontally, and the early varieties of the Cherry may also be trained in the same way, and for such the wires should be fixed at about 9 inches or three courses of bricks apart; but in the case of the Peach, Apricot, Plum, and Morello Cherry, in order that such trees may be properly trained, the distance between the wires should not exceed 3 inches or 4 inches, or a wire for each course of bricks.

Walls on which Roses and other flowering plants are intended to be trained are sometimes fancifully wired, that is, vertically, diagonally, &c., but the horizontal system of wiring garden walls is that most frequently practised, and is no doubt the best.—P. GRIEVE.

—“W. C. B.” should build his walls with stone and face them with brick. There will be no danger of the two materials parting company. To build them wholly of stone would no doubt be the most economical, as he says it can be procured on the place; but unless stone walls are wired they make bad subjects for training fruit trees against; besides, stone does not absorb the same amount of heat as brick. He should make the wall against which he is to build his houses wholly of stone and face it with cement, as the trees which he intends to grow against it can be trained to a trellis. In height it should be 15 feet; 12 feet would either give a

short rafter or a flat pitch to the roof. Fourteen feet would not be too high for the walls, which will run at right angles to the one which will be covered. The height he proposes (7 feet) would afford but little protection in an exposed position; besides, a 7-foot wall would not afford room for the proper development of the trees to be grown against it. Seven feet would be high enough for the wall which will face the north, for if made too high it will shade too much of the lower portion of the garden. The wall facing the west he could plant with dessert Pears, Plums, and Cherries, while that on the opposite side could be planted with culinary Plums and dessert Cherries. The low wall should be reserved for Morello Cherries, Gooseberries, and Currants—the two last will come in for late use.—D. GRANT, *Castle Ward*.

NOTES.

A NOBLE ZEPHYR FLOWER.—Zephyranthes Treatiæ (Amaryllis Treatiæ it is also called in gardens) is one of the prettiest of all the Zephyr or "West Wind Flowers." To see these flowers in all the beauty of vigorous growth and wild, floriferous habit one must go to Ceylon, where they are used for edgings to beds and walks or for borders near the house. I never saw them prettier than growing apparently wild in a little tropical meadow facing the house of Dr. Veitch, when he was colonial surgeon in Penang. They evidently liked the shelter of the Grass, and their pink or white stars were most lovely as seen nestling in the herbage among their own glossy green leaves and pink-tipped buds. *Z. Treatiæ* is now in flower in a greenhouse at Mr. Ware's nursery, and is one of the finest of its race, bearing erect, pure white, six-petalled blossoms on slender stalks 3 inches to 6 inches high. Of all the Zephyr Flowers, this one and the rosy red *Z. carinata* would appear to be the best and most easily grown.

ENGLISH PLANT NAMES.—I often think that the question of English names requires a little explanation. When we see Professor Owen using English names for his garden birds, in addition to the Latin ones, we may be excused for asking why gardeners or why botanists are denied a like privilege. Latin names, being understood by persons sufficiently interested in science all the world over, must ever and always be used; but this much allowed, some of us claim in addition that every plant grown in English gardens must have an English name, not as a substitute, but as a necessary addition to the Latin one. If Latin names are allowable for the use of savants, why are English ones not allowable for the use of the masses who are not savants? In order to make gardening and botany "understood of the people," English names translated or original as best may be, but English names of some sort must perforce be used—in point of fact are being so used every day. All that is wanted to make them universally used is a little more opposition.

ST. BRIGID'S CHRISTMAS ROSE.—Allow me to say one word more in reference to this variety of Christmas Rose. I find that there is a very great demand in London nurseries just now for this fine old garden plant, the typical plant *Helleborus niger*. The Christmas Rose is figured in the *Botanical Magazine*, t. 8. *H. niger maximus* (*H. altifolius*) has been figured in THE GARDEN, and is rightly called "The great Christmas Rose." It may interest some to know that this last is grown by the thousand by Messrs. Backhouse at York, and by Mr. Ware, of Tottenham. Mr. Ware, jun. (who has just started a Hellebore farm near Bath), wishes to procure plants of the true St. Brigid's Christmas Rose, and I shall send him a bit of it; but as it is grown for sale by the acre in the neighbourhood of Manchester, that seems to be the best place to procure stock of it. I have had many applications for this plant, and am sorry that I cannot give more of it away; but I am quite sure Mr. Brockbank will not object to inform any *bona fide* amateur as to where it may be purchased.

THE BEST GRAPE HYACINTH.—All the species and varieties of Muscari or Grape Hyacinths are interesting, from the pure white form of *M. botryoides*, the buds of which remind one of a cluster of pearls, to that weird monstrosity yclept the "Feather Hyacinth," in which the flowers are to some extent suppressed, and in their place a mass of *Rhus Cotinus*-like purplish filaments are produced. The best of all the blue kinds is one we recently saw in Ware's nursery under the name of *M. atlanticum* (? *M. Szovitzianum*), a stout growing form with oblong clusters of dark blue bells at the apex of a scape 6 inches to 8 inches in height. The clusters of flowers are about 3 inches in length, and strike one as being bolder in form and brighter in colour than any other variety of *M. botryoides* which we have ever seen.

HOOPED PETTICOAT DAFFODILS.—On some soils and positions, even in the extreme north of England and also in Scotland, these golden chalice flowers are quite at home, and flourish from year

Varieties of *Narcissus Bulbocodium*.

to year in the open air; so also, as I am told, in Ireland. What they seem to like is drought and heat in the summer and autumn just after their foliage dies off naturally. The large sulphur *Corbularia* recently figured from Miss Jekyll's garden is of all one of the finest, and has this year been brought over by the thousand, so that for the future it will perhaps cease to be a rare plant. Those here figured, although merely forms or varieties of *N. Bulbocodium*, are distinct and pretty now with us in pots. The upper flower may be called *N. Graellsii minor*; colour pale sulphur, greenish behind; the lower flower is bright rich yellow. Those who think *Narcissus* golden should place a watch or a coin near a "golden" yellow flower and note how they differ. Mr. Barr grows several kinds well in raised beds and also in pots, protecting them when at rest by a cold frame or glass covering. It is not cold that these little bulbs fear, but too much wet at the wrong season.

SNAKE'S-HEAD FRITILLARY.—We do not make such good use of these quaint old flowers, varieties of *Fritillaria Meleagris*, as we ought to do in our modern gardens. Originally native of our own land as of other parts of Europe, we have now

many kinds of garden origin, and the best of these both white and coloured are worth the most skillful culture we can give them. Blooming with the Daffodils, they also with them have to face the winds of moody April. Many varieties which we saw at Ware's lately struck us as being singularly beautiful as they swayed and nodded in the wind. In early morning or at the close of day they are prettier than at any other time, as the sun shines through their segments and brightens their chequered markings. As seen in the waning sunlight, these flowers actually glow again with colour and reflected light, and in form also are not a little suggestive of lamps and lanterns as they glisten in the breeze.

RARE HARDY FLOWERS.—Among the hardy flowers we saw at Ware's nursery, at Tottenham, the other day the following were of especial interest; the Prophet Flower (*Arnebia echioides*) was opening its spotted yellow flowers in a cold frame, while in sheltered beds outside the Wood Lilies, *Trillium erectum* (purple) and *T. grandiflorum* (white), were opening their flowers. A bed of *Primula cashmeriana* in full bloom was a pretty sight to see in the evening sunlight, and by the Daffodils and Fritillaries, masses of *Adonis vernalis* displayed their starry flowers of greenish gold among their feathery foliage. *Podophyllum Emodi* displays its white cups above its drooping olive-green leaflets, and in hollow beds the Bamboos are putting forth their new leafage. Among the Fritillaries one of the finest is *F. latifolia* (Black Knight), bearing a shapely bell of a soft bronzy yellow colour heavily blotched and chequered inside with dark brown. Grape Hyacinths and Virginian Lungwort (*Pulmonaria virginica*) are in flower, as is also that noblest of all large-leaved Saxifrages, *Megasea purpurascens*.

TRITELEIA UNIFLORA.—Of this old and hardy bulbous plant there are two distinct forms, the one producing white stars an inch or more across, the perianth segments being delicately shaded with blue, while in the other form the segments are narrower and wholly blue in tint, and as seen in the mass they give a lovely soft coerulean hue to a bit of bare earth in a sunny place. It is commonly called the Garlic flower, and yet so deliciously sweet are the outspread blossoms themselves as they shiver in the sunny breezes of April, that the bees love them and cluster over the flowers almost as lovingly as they do on the *Eupatorium* blossoms, or on the Cauliflower-like corymbs of the rosy *Sedum* spectabile in late autumn. I saw some large beds of this Garlic flower the other day 6 yards or 8 yards square, and very pleasing they were in the warm sunlight, with the soft murmur of bees among them. In some of these beds the two forms, the white and the blue, were mixed, and the effect so produced was a very good one. The only drawback is the strong Garlic-like odour of the leaves and flower-stems when cut or trodden upon.

WINTER ACONITE AND SNOW GLORY.—A very pretty combination in the floral way suggested itself to me the other day. It is this. How well a bed of Snow Glory would look if the bulbs were intermixed with tubers of the winter Aconite. Of course they would not flower together, but the Aconite would enliven the bed with its golden cups long before the *Chionodoxa* appeared, but the best effects would be seen just as the latter opened its little blue buds among the Fan Palm-like foliage of the *Eranthis*. Here with us the Snow Glory does not open its first flowers until the Snowdrops have departed, or that would be a combination very difficult to surpass. *Iris reticulata* and *Eranthis* is another good arrangement, not in a bed perhaps, but a good clump of each side by side looks well. In an old garden yesterday I saw clumps of *Narcissus Bulbocodium* blooming quite freely alongside a long edging of *Iris pumila* varieties, and the gold and purple colouring as seen in chequered sunlight beneath some gnarled old Apple trees in blossom was very lovely.

VERONICA.

NOTES ON BIRDS

In the Garden, Sheen Lodge, Richmond Park.
(Concluded from p. 385.)

VERY welcome are the occasional, but too rare, visits to the garden of the RING DOVE (*Columba palumbus*), the STOCK DOVE (*Columba ænas*), and the TURTLE DOVE (*Columba turtur*), all of which nidificate in the park and adjoining woods.

A pair of PARTRIDGES once nested in the garden next to mine belonging to a residence not then tenanted. I was surprised to see them occasionally running across the lawn.

A PHEASANT (*Phasianus colchicus*) from the adjoining preserve will now and then visit my poultry-yard. The intruder is a descendant of the old Euxine species introduced by the Romans from the banks of the Phasis, and is usually indicative of the oldest preserves established and kept up in Britain. The ring-necked variety from China is more common in later preserves; and the Japanese rather heavy flying variety with an addition of green to its gay plumage is the latest importation of the luxury.

At one time the WILD TURKEY (*Meleagris pavo*) was abundant in the park. I learned this from the father of the present excellent head keeper whom he succeeded in the office. I had asked the reason of the many fine old Oaks which had been pollarded, and which contrasted their huge bush-like forms with the more picturesque branching of the naturally grown trees. Mr. Sawyer told me it had been done in George I.'s time to afford roosting places for the wild turkeys upon the outstretched horizontal lower boughs of Oaks so treated. These fine birds afforded favourite sport to both the First and Second Georges, but they were so tempting to outsiders, and the affrays between keepers and poachers became so numerous, dangerous, and sometimes fatal, that early in the reign of George III. that benevolent monarch ordered the extirpation of the tempting exotic Gallinæ.

And here I cannot resist recording an incident in my own experience. A friend presented me with a pair of white turkeys. My neighbouring keeper one day informed me that the hen bird had made her nest in the adjoining preserve and was then "sitting;" but, he added, she would do no harm there, and should not be disturbed. Her mate regularly took up his quarters at night on an overhanging branch and roosted there, coming home, of course, in the daytime to feed. One morning the keeper looked in upon me with a grave face and said that a fox had trespassed in the preserve and had killed the cock bird. He begged me to return with him to the spot, and led me to where the poor turkey lay with much of the breast devoured. He showed me also the footprints, evidences of struggles, with down-trodden herbage and scattered feathers leading from the bush in which the female was still safely brooding to the final fighting ground. She apparently had not been disturbed. Now, our common inference was that her mate had discerned the stealthy approach of the fox, and had descended to do battle with the intruder; that such a conflict had been severe was too plain. The gallant bird had succeeded in drawing off the fell carnivore from the nesting-place of his mate, and finally had fallen a sacrifice to conjugal devotion.

"I think," said the keeper, "we might have a chance of catching that fox, if you can spare the bird to bait my traps." I assented willingly. He set three traps not far from the nesting-place with tempting portions of the victim's carcase. One night passed and a second without results; but on the morning after the third my neighbour looked in with exulting countenance, and reported reynard caught. I accompanied him to gloat over the culprit. "Ah!" said he, "I know him; he comes from Wimbledon; they are the hardest of all them vermin to shoot, is them foxes."

I may plead that we have no "hunt" in our vicinity. The female turkey hatched out her brood and brought all her pretty milk-white chicks safe to the poultry yard.

Returning to my favourite warblers, I may finally note the period of the twenty-four hours when their music can be most fully enjoyed.

With so many and such varied songsters one is apt to be disappointed at the shy and scanty performance in an afternoon's ramble or rest in the garden. Towards sunset, indeed, there are additions to the warblings of thrushes and blackbirds, and later on the nightingales exclusively hold concert and monopolise a grateful attention.

There is, however, a period in the twenty-four hours in which the whole strength of the avian orchestra may be heard, and the only period in my experience. The enjoyment involves quitting the pillow and gaining a retired seat in the garden as soon as there is light enough at early dawn to find one's way, say on a morning promising the poet's May weather any time in that month.

On such a day and hour, say 3.15 a.m., I have betaken myself to a seat beneath the old Cedar in the middle of the shrubbery division of the garden where the main business of incubation and brood-rearing is carried on.

As the Command is being fulfilled, and light prevails, a few faint chirps and trills may be heard here and there from newly-awakened sleepers at the nests. These gain gradually in strength and distinctness, and specific notes or "motivos" can be recognised (friend Gould's tuition aiding). Soon are added the luscious warbles of the larger songsters, and the nightingales, unwearied by nocturnal trills, join the morning concert. The varied songs come from all parts of the shrubbery; the singers still remain near their sleeping-perches and nesting mates. Not a sight is seen or flutter heard of an active bird; no foreign sound save, perhaps, the distant sigh of an early train jars upon the marvellous crescendo.

In this concert the counter-tenor of the cuckoo and the monotonous of the shriller cuckoo's mate chime in. To these are added the delicious soothing tenor cooings of the turtle doves, with the louder, clearer cries of the jays, from the contiguous woods. The daws, rooks, and the carrion crows with their harsher caw contribute a bass.

This glorious greeting of coming day continues as the light increases till the sun rises in his splendour. He is ushered in with such a "morning hymn" as may give a new pleasure even to an angelic host.

By degrees one vocalist after another becomes silent; the flutter of little wings succeeds the warbling of little throats. The unfeathered fledglings have awoke and opened wide their beaks for breakfast. Work comes after praise; business succeeds to pleasure; the garden is now alive with the fitting quests of parents after larvæ or other soft food.

In the blaze of sunlight one returns, perhaps, again to bed, nothing of the morning concert remaining save the cuckoo's cry and occasional caws from the rookery.

In reference to the sixty species of British birds, the subjects of the foregoing remarks, I may state that my garden has an extent of over three acres. Plans of it and of portions of it were taken for the editor of THE GARDEN, and may be found in the weekly issues for August 17, 1872, and for April 21 of the current volume. RICHARD OWEN.

Thrush and blackbird v. slugs.—Professor Owen is so very accurate an observer, that I should not think of disputing any statement he might make. But one point in his pleasant account of the birds at Sheen Lodge (p. 350) is so contrary to my own observations, that I should like to know how far it agrees with the experience of other observers. Professor Owen says that he has no slugs or snails in his garden, and that "the extirpators are the thrush and the blackbird." I know that thrushes eat a large quantity of snails in hard weather, but I did not know they eat slugs. I have certainly an abundance of thrushes and blackbirds here, but I have also an abundance of slugs. If the thrushes would clear them off, they should be welcome to my Cherries and Strawberries. I have heard of slugless gardens, but I

think the soil has more to do with that than thrushes.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

—Professor Owen (p. 350) tells us that blackbirds and thrushes eat slugs in his garden. I wish they would do so in mine; but I have in vain watched them in the early morning when the dewy lawn is covered with slugs, and have never seen any bird except a duck eat a slug. For many years I have tried to obtain direct evidence that blackbirds eat slugs, but have failed. I know that both blackbirds and thrushes feed largely in autumn upon shell snails, and Yarrell, Gould, and other writers on birds have stated that they eat slugs too, but I have never met with anyone who could confirm the statement by his own observation, though I have often raised the question. Two or three years ago, when the blackbird came out in the second edition of Yarrell, the list of its food as given in the first edition remained unaltered. I wrote to the editor, whom I know calling his attention to it, and asking his opinion. He told me that he did not believe that either blackbirds or thrushes fed on slugs. Gould gives in detail the contents of the stomachs of three or four blackbirds which he examined, but no slugs were found in them. All this is only negative evidence, and it may appear captious to question what is so generally believed, but these birds appear to me to have a special aversion to the slime of slugs, and to avoid them accordingly.—C. WOLLEY DOD, *Llandudno*.

FRUIT GARDEN.

PEACH CULTURE AT KETTON HALL.

AMONGST indoor fruits Peaches hold a prominent position here; a range of houses 180 feet long and 11 feet wide in three divisions, having a trellis in front and also trees on the back wall, has just been erected for their accommodation. This range as well as others here is built and glazed on Rendle's system, and heated by two rows of 4-inch pipes along the front, with the necessary valves and mains. It is intended ultimately for early varieties, numbers of which are now on trial in other houses. The whole of the front lights are made to open, and the glass being in large squares fixed in metallic bars, they have a light and ornamental appearance. Roof ventilation is also amply provided. In front of and parallel with this range is another span-roofed house 100 feet long and 22 feet wide, in which there is an arched trellis occupying the whole width and planted on both sides mainly with mid-season Peaches. This house is heated by means of three rows of 4-inch piping, each side working independently, and is ventilated in a similar way to the previous range. Next comes the orchard house, a noble structure and worthy of the fine collection of trees which it contains. It is a curvilinear span-roofed house, 150 feet long and 28 feet wide, with iron rafters and a trellis on each side, the centre of the roof being left clear to admit the necessary light to the trees in pots, which occupy a space on each side of the centre walk. Three rows of 4-inch piping run the whole length of this house on each side, thereby rendering this "garden of fruits" secure against March winds, so disastrous to outdoor Peaches. The trained trees, from their size and vigour, appear to have been years in their present position, while in reality they were planted last October, the building of the house not having been commenced till the previous month of June. The trees in pots include Peaches, Nectarines, Figs, Plums, Pears, Apples, and Cherries, and form a most interesting collection. A span-roofed house made of wood 90 feet long and 16 feet wide, unheated, is occupied by Tea Roses and late Peaches, the border being utilised for Violets, salading, and early vegetables. The following list of Peaches and Nectarines in cultivation here may be interesting: The Peaches consist of A Bec, Alexander, Alexandra Noblesse, Barrington, Bellegarde, Belle Beauce, Crawford's Early, Chancellor, Dagmar, York, Dr. Hogg, Early Beatrice, Alfred, Louise, Dymond, Albert, Rivers' Exquisite, First Lord

(seedling), Goshawk, Grosse Mignonne, Hale's Early, Late Admirable, Lord Palmerston, Merlin, Morris' White, Noblesse, Nectarine Peach, Prince of Wales, Princess of Wales, Red Magdalen, Royal George, Sea Eagle, Stirling Castle, Violette Hâtive, Walburton Admirable, and Waterloo. It will be seen that amongst these there are many new kinds, of the value of which I hope soon to be able to give some account. The Nectarines consist of Albert Victor, Dryden, Downton, Early Newington, Elruge, Hardwick Seedling, Hunt's Tawny, Humboldt, Lord Napier, Pine Apple, Rivers' Orange, Stanwick Elruge, Spencer, and Victoria.

W. W.

FLUED WALLS.

It seems strange with all their advantages that these should have gone out of use, or rather that we should not have improved on them and had hot-water pipes, as one or two of these confined in a hollow wall would no doubt, even in the worst of seasons, secure a good crop of fruit, as with the bricks uniformly warm throughout radiating heat all night, frost would be repelled from the fresh tender blossoms. In the small space forming the cavity of a wall 10 feet or 12 feet high, it would not require much fire nor a very powerful boiler to keep up a high temperature within, and as the heat would only be required for a month or six weeks at most, the cost for fuel would be a mere trifle. If we are to have seasons like the present, and those for many years past, it is evident something must be done, or we shall soon have to give up attempting to grow Peaches, Nectarines, and Apricots out of doors, as in most places the trees are sadly crippled, and in many they are ruined or dead altogether. Glass, no doubt, is best, and next to that hollow walls with a pipe at the bottom, so that heat could be turned on and off at pleasure to protect the flowers or help to ripen the wood. Hollow walls would even gather warmth of themselves by absorbing sun heat; and though those of solid construction do this in some measure, they do not do so to the same extent, as beyond the solid brick there is nowhere to store the heat. Hollow walls have also other advantages—they are drier, and dryness means warmth and a great help in setting fruit blossoms, which often fail through damp. Hollow walls are, moreover, cheaper than solid ones, as the latter, when of any height, must be 14 inches thick, the building of which swallows up many bricks, whereas $\frac{1}{4}$ -inch brickwork with ties across does for the former if the mortar and work are both good.

S. D.

VINE TENDRILS.

THE production of tendrils in place of bunches, as described by "Vitis" (p. 371), is doubtless simply the result of last season's wood being insufficiently matured. The Vine is naturally so disposed to bear, that, except through excessive weakness, it does not fail to show fruit in larger quantities than it can support if the preceding summer's shoots have been ripened properly. "Vitis" does not say what kinds the Vines are in his different houses, but he is no doubt aware that there is a good deal of difference in the time and means required to effect the ripening process necessary to insure a crop the ensuing year. Early varieties, of which Black Hamburgh and White Frontignan may be taken as examples, require a short season to ripen the crop and wood compared with such sorts as the Muscats, Gros Colmar, or Gros Guillaume (Barbarossa), the last of which requires the most hardening up of the wood if bunches instead of tendrils are to be expected the spring following. The fact of "Vitis" being in a position to see the shortcomings of his Vines by the latter part of April shows that they have been started time enough to allow of the wood being this season matured in a way that will prevent a like disappointment next year. Unless he happens to be in one of the worst sunless districts of the kingdom, he will have no difficulty in getting the wood of the earlier varieties into fruitful condition by simply shutting

up the house every afternoon whilst the sun is on the glass with enough power to get the temperature well up. In the case of late sorts, or such as the Muscats that require more heat, some fire should be used in dull, damp weather, with watchfulness as to the early closing, so as to make as much use of the sun as possible, and so minimise the expenditure in fuel. If "Vitis" will follow this course so as to get his shoots brown and hard all their length to where he first stops them whilst the leaves are green and healthy, he will not next year be troubled with tendrils instead of bunches.

T. B.

Charcoal in Vine borders.—So far as my experience goes charcoal does neither good nor harm in Vine borders, and if I could get it free of cost I would never use it in them, except I had a stiff, cold loam to deal with. In that case it might be of some service, but I should prefer to use a liberal supply of old lime rubble in its place. There are hundreds of gardens in which good Grapes are grown without the aid of charcoal—sufficient evidence that it is unnecessary except in exceptional cases.—J. C. C.

Coverings for Vine borders.—"J. C. C." is the first, I think, who has recommended stone flags as "generators" of heat for covering Vine borders. "The warmth generated by these stones would bring the roots near the surface," he says. If he will test a flagged border by a thermometer and another not so covered, he will find out his error. Flagstones are only warmed by the sun, and a border can be better warmed in that way without them. Light coloured flags, indeed, keep out the heat, and at the best they cannot possibly increase the average temperature of the soil. A "generator" of heat I apprehend to be a body that evolves heat of itself by fermentation or combustion.—S. W.

Black Prince Strawberry.—I was glad to see (p. 360) that good old Strawberry, the Black Prince, favourably noticed, as, though very old, it is the best early kind in cultivation. Some thirty years ago this and the Roseberry used to be the principal sorts grown for forcing first, and prodigious crops I have seen on the Black Prince. It is a free bloomer and setter, one peculiarity of it being the way in which it carries its petals, which remain quite fresh at the back of the fruit till it is ripe. Black Prince was brought into notice by Mr. J. Cuthill, at one time a market gardener at Camberwell. As Mr. Muir says, it is not only a good cropper indoors, but a capital one out of doors, and it is ripe nearly a fortnight before any other. Its small size is the only thing against it. It is a small, conical-shaped fruit, and, as its name implies, very dark in colour, and being highly varnished when ripe, the fruit is very rich-looking. It is a kind well adapted for a sloping bank or sunny border to get a first picking from, and to grow in pots for forcing for the same purpose, but few would be satisfied with it after Keen's Seedling or the Vicomtesse Héricart de Thury comes in. Keen's, however, is the best of the two, except for packing, for which it is too soft. The Vicomtesse, being more glazed and firm, bears packing well.—J. SHEPPARD.

History of Grapes.—I agree with your correspondent (p. 360) that it is desirable the history of our cultivated Grapes should be correctly known, and that the honour of raising them should go to whom it is due, but the history of the Abercainey variety as given by your correspondent is not correct. It was not John McIntosh, sen., who raised this Grape, but my predecessor, the late James Arnott, who was gardener here for thirty-five years, and who succeeded Charles McIntosh, jun., and the Abercainey Grape was not in existence for ten years after Mr. McIntosh had left here. There are still living several individuals acquainted with the circumstance, and one of them still connected with the gardens remembers the first fruit it bore. It has never to my knowledge been known as Moray's Grape, but as Arnott's Abercainey Seedling. Several years ago I had occasion to renew the house in which the original Vine was growing. I preserved it,

and have since grown the original and its progeny alongside West's St. Peter's, which here is quite a distinct Grape. Mr. Gilbert knows the Abercainey, having received it from me several years ago. Mr. Barron has now also got the true Abercainey, and in due course we will have his opinion on its distinctness of character. The keeping qualities of Lady Downes the Abercainey has not got, but being of a very hardy constitution, a free bearer, and good in quality, the Abercainey comes in handy after Hamburgs and before Lady Downes.—J. BROWN, *Abercainey, Cricff.*

PLANT NOMENCLATURE.

(HELLEBORUS NIGER ANGUSTIFOLIUS.)

ON every occasion on which, as in the case of this Hellebore, someone objects to a new varietal name, given to a plant by someone else, the whole subject of popular nomenclature again presents itself. I should imagine there are few people who have a liking for plants who would not prefer an appropriate expressive name in their own tongue to the often hard and sometimes far-fetched names in a dead language, given by botanists, if the change was not beset with difficulties. Anyone who doubts this has only to look at the last phase of the question, as propounded by Mr. Burbidge and accepted by Mr. Tymons. Mr. Burbidge disclaims any intention to supersede Latin names by popular ones, and approves of the use of both, and Mr. Tymons coincides with the idea. It seems superfluous to say that the use of names is simply to enable people to understand what is meant in speaking or writing of the things named. In the name of all that is reasonable, is the change proposed to be effected to be at the cost of having continually to be tackling the scientific name on to the popular one when speaking or writing of plants in general? If the result arrived at by Mr. Burbidge and Mr. Tymons means anything, it means this.

When an undescribed plant reaches the hands of the botanist, he gives it a scientific name, possibly not in all cases the most appropriate, but the name remains; no one in any country attempts to interfere with it. But what do we see in popular naming? The inevitable confusion certain to follow is foreshadowed by the case before us. Mr. Burbidge gives this particular Hellebore the name St. Brigid's Christmas Rose; then down comes Mr. Brockbank on him and will not have it at any price; then someone suggests another name, and with equal right a dozen or a score others may give it as many more as they choose. The whole business breeds nothing but confusion, as if there was not enough already in the same direction. Depend upon it there is nothing to be gained by the change except increasing the number of perplexing aliases. There will not be a single individual less to like flowers or grow plants on account of the harsh Latin names which many of them possess. No one objects to the familiar popular names borne by the comparatively few plants with which everyone is acquainted and knows them by, and if the kinds of plants in general cultivation could be reckoned by the score or hundred, then there would be no objection to the additional names proposed. But the field is too vast to venture on without getting into inextricable confusion, such as will necessitate giving a string of synonyms to make one's self understood when either speaking or writing of plants.

If even, instead of each individual who chooses to set up re-naming plants, the whole of those so disposed were to jointly deliberate and give the best English name they could devise for a plant, how are they going to get people to adopt it in the same way that they accept the authoritative Latin name given by the botanist by whom the plant is first described? The result would just be this: some would adopt the popular name and others would not acknowledge it, and in each case would give so little heed to the course followed by the others, as to not recognise the unfortunate plant when spoken of.—T. B.

— The subject of English plant names is daily becoming of more importance as (in great part, thanks to THE GARDEN) the cultivation of hardy

plants spreads amongst us. There is now an actual want for a trivial vocabulary, and if such want is to be supplied, the new names ought as far as possible to be of a kind easily to be remembered, and to some extent systematically arranged. There are many species of which the English names are amongst our earliest memories, and which none would wish to change; but in the invention of new terms, or the re-application of old ones, should not great care be used that the memory should be burdened as little as possible by non-relevant matter, and that the words used should be as far as may be intrinsically significant? No hard and fast rule is required; it is merely suggested that the second English name should in the main be co-extensive with the botanical genus, and that the first English name should be shortly suggestive of a prominent feature of the plant, or be in some sequence to its time or mode of flowering or the like. To refer to your pages of late, is not *Satin Flower* much to be preferred to *Rush-leaved Lily*? The former was first in the field, and could be adopted as a generic term; as to the latter, the Lilies have had too much to bear lately. Surely our language is not so poor but that another name could be found applicable to a somewhat Lily-like flower. *Plantain Lily* has taken root, and so should not be disturbed; yet it would, perhaps, have been wiser to search for a more distinctive appellation for the genus *Funkia*. Your suggestion, *Great Christmas Rose* for *Helleborus niger maximus* fills every want, whilst *St. Brigid's Christmas Rose*, though euphonious, is faulty in that the specific term is without significance. To remember the name of a genus is comparatively easy; species and varieties trouble the young gardener more, and if the specific name gives him a hint either in the plant as he sees it, or in his memory as he has seen it, the difficulty is almost overcome. Queen Anne's Jonquil requires an effort of the mind to connect with the flower, but who, once having seen, could forget *Codlins* and *Cream*, *Butter* and *Eggs*, or *Sweet Nancy*? To proceed with examples would be endless, there being now no authority, and the class, whose use is to be the ultimate judge, is only now coming into existence. If certain lines could be laid down within which the fabrication of new names should for the most part lie; if rules could be devised as to the forms which would give us a clear, easy, significant English terminology, which would advance within limits *pari passu* with scientific nomenclature; THE GARDEN would add much to its present and prospective usefulness by taking up the subject.—
RHO.

BIRD AND PLANT NOMENCLATURE.

I WAS glad to see Mr. Tymons' sensible and pointed letter on plant nomenclature in this week's GARDEN, for though I thought it had been pretty well discussed some years ago, yet superstitions die hard. There is a capital instance of the confusion which results from incorrect nomenclature in Professor Owen's notes on birds in THE GARDEN; and if it were not for the Latin names (of which, however, many are obsolete or incorrect) I should not always have known what birds were alluded to. Professor Owen calls the lesser redpole (*F. linaria*) the linnet, whilst he calls the real linnet (*F. cannabina*) the greater redpole, a name certainly not in common use; but perhaps he does not mean the linnet after all, as he says it always breeds on the ground; and though I have seen many linnets' nests, not one was on the ground, nor have I heard of this being a usual occurrence elsewhere. But Latin names when used incorrectly may be as misleading as English ones, and I was not a little astonished to find the wren, the chiff-chaff, the redstart, the robin, and the wagtails all put down under the genus *Motacilla*, which by modern ornithologists is applied to the wagtails only. Considering that the above-named birds belong to three different families, it is strange to class them all in one genus whilst other and nearer allies are allowed a separate genus. I can only guess what bird is meant by the "garden warbler or lesser fauvette (*Motacilla passerina*)."

It cannot be the real garden warbler, as that is mentioned lower down under its right name. *Motacilla passerina* is not a correct name for any English bird, though I find it given as a doubtful synonym, never in general use, for the lesser white-throat (*Silvia curruca*). But this bird does not, like Prof. Owen's, imitate the notes of others, as far as I know, and I can find no mention of this habit either in Yarrell or Dresser. Lesser fauvette is not an English name for any bird, though fauvette is a French name for warblers in general, and has been sometimes used for the garden warbler in English books. The blackcap might be intended, as this fine songster does imitate other birds' notes, or it may be the white-throat or lesser white-throat, neither of which seem to be mentioned in these notes, though both should be found at Richmond. Ornithological nomenclature is a bad subject to meddle with, but as regards British birds I think it is now placed on a satisfactory footing, and as every boy knows the English names for the birds mentioned in these notes, I see no object in using the Latin ones except in writing for foreigners.

But with plant names it is different, as their number is ten times greater, and only the commonest plants have English names which everyone knows, whilst gardeners of the most humble pretensions know and use the Latin names.

What we want is to understand each other as accurately and quickly as possible, and the attempt to introduce a crowd of new fanciful names is not the way to attain this object, or to promote horticultural intercourse with other countries.

H. J. ELWES.

GARDEN NOVELTIES AND FASHIONS.

I WISH there was less of "follow my leader" and more independence of thought, and particularly of expression, amongst us gardeners; if that were so, fewer amongst us would have cause to regret having acted, to say the least, indiscreetly in purchasing novelties simply because they are said to be improvements, and that someone has tested them and declared them to be such. Granted that they may be, it does not follow that we are to resign our own judgment in the matter and grow these said novelties in full confidence that they will turn out the trumps they are said to be. The proverb runs "old birds are not to be caught by chaff," and I suppose it is that having been bitten more than once with the novelty fever, I am the more chary of novelties now, and anxious to warn younger hands against them, or at all events to be sceptical about them till they have had time to test them, or at any rate to think the matter over for themselves. I would not for a moment be understood as implying dishonesty to anyone who fathers these novelties and designates them, whether they be so or not, first rate; from their stand-point they doubtless are, but then our stand-points differ, as they ought and will, just in proportion as each of us brings to bear our own judgment on whatever novelty is in question. The first step to attain this independent state of mind is to pay no heed to orthodoxy in anything pertaining to the profession, as, for instance, when a man says that we only require two sorts of Grapes, viz., *Black Hamburg* and *Muscat of Alexandria*, dare to tell him that that is an old story, but still fashionable, and therefore frequently repeated, because it is considered the correct thing; but it is a fallacy nevertheless, and it is time it was buried. Of course if I must grow only two kinds, I am willing to be fashionable, as these are the two very best, but I have heard this speech from people who grow at least a dozen kinds, and how they can reconcile the speech with their practice is more than I can imagine. Moreover, a general verdict does not always prove to be a correct one. I can prove the correctness of this assertion by again referring to Grapes. *Madresfield Court* a year or two after being sent out was almost unanimously condemned, first for its persistency in cracking, and next because it had been sent out as a late Grape, and yet it would not keep; happily, there are a few "sticklers" amongst us, and so this noble Grape was given special treatment and

grown as an early Grape, and the popular verdict now is on the right side, and I venture to prophesy that a similar favour awaits the much abused *Golden Queen*, of Pearson, and also Mrs. Pearson. This last variety I consider about the most valuable of all the new Grapes added to our collections in recent years, not even excepting *Madresfield Court*. Other instances might be quoted, but these are ample to illustrate my meaning, and I think also to show the importance of each and all of us, whilst paying a respectful deference to the opinions of others, not to neglect the cultivation of an opinion of our own.

W. W. H.

GARDEN FLORA.

PLATE CCCLXXXVI.

BEAUFORTIA SPLENDENS.

THE singularly beautiful flowers represented in the annexed plate show an arrangement of floral organs peculiar to a great many Australian plants—an arrangement which has won for them the appropriate name of *Bottle-brushes*. In the whole of the *Beaufortias*, *Callistemons*, *Metrosideros*, *Melaleucas*, and other plants not so well known in gardens the long and richly coloured stamens form the attractive portion of the flowers, which are arranged in a manner more or less similar to those shown in the accompanying plate. In *Acacias*, *Eucalypti*, and other long-stamened plants the beauty of the filaments is peculiarly striking. Australia is the home of some of the most remarkable of Flora's freaks as well as of many of the most beautiful, amongst which the *Bottle-brush* plants are especially striking. Some years ago the *Beaufortias* and *Metrosideros* were general favourites, and good well-flowered specimens of them were often seen at our great plant exhibitions. That was in days when hard-wooded plants were the test by which gardening skill was measured, a position now held by the *Orchid* family. The grace and beauty of the plant here represented should, however, recommend it to the notice of even the most enthusiastic *Orchid* lover, and although such a plant may not have such charms for him as some *Orchids*, yet there seems no reason why such a beautiful and easily grown shrub should be so little cultivated as it is at present.

I have seen specimens of *B. splendens* as symmetrical as a *Box* bush bearing dozens of its rich scarlet flowers, which were admired by all who saw them, and almost as much may be said respecting the rest of the Australian *Bottle-brush* plants. They have only to be well grown to prove of the greatest service as garden plants. In order to encourage a taste for such plants as these, would it not be well to have a class for them in our plant exhibition schedules? At most shows now-a-days *Azaleas*, *Pelargoniums*, and similar plants fill the stages—handsome enough plants, no doubt; but if floral exhibitions are intended to bring into notice the most interesting and useful of garden plants, the schedules must be arranged different from what they now are.

BEAUFORTIA SPLENDENS is a garden name given to *B. sparsa*. It was grown at Kew nearly a century ago under the latter name, the former name having been given some thirty years afterwards, when it was re-introduced and figured in Paxton's "*British Flower Garden*." Like all the Australian *Bottle-brushes*, it is a greenhouse plant, a free grower, and, when its wood is well ripened, a free flowerer. As will be seen, the blossoms are produced on the ends of the one-year-old growths, a fact to be remembered, as I have known some

BEAUPORTIA SPECIOSA

growers unacquainted with this cut back their plants to induce them to break well, and in so doing of course sacrifice the flowering wood. The flowers in a cut state last in good condition for several days in water, though it will be seen that to cut this year's bloom, one must needs sacrifice the next crop. On well-grown plants the length of the inflorescence is from 4 inches to 5 inches. *B. decussata* resembles this species in habit and appearance. As the name implies, the leaves, instead of being irregularly decussate along the stem, as in *B. sparsa*, are placed decussately or cross-ways. The flowers, too, are not so thickly placed as in that species, though in the colour and length of the filaments there is little or no difference. It is an erect-growing, twiggy shrub, about 4 feet high, and makes a good specimen plant in about four years from cuttings. Of allied plants whose floral arrangement is similar to that of *Beaufortia* there are

METROSIDEROS SPECIOSA, which, as well as *M. lanceolata*, is often met with under the name *M. florida*, a totally different plant with globose heads of flowers produced on the ends of the ripened wood. *M. speciosa* is an erect growing plant with stiff ovate foliage, and its flowers are produced in the axils of the leaves along the ripened wood. The stamens are bright scarlet, and although not so long nor so numerous as in the plant here figured, they are nevertheless very ornamental. *M. lanceolata* is very similar to the last named kind, differing only in the shape of the leaves, which are longer than in *M. speciosa*, and, as the name signifies, lance shaped.

CALLISTEMONS have been represented in gardens by several very handsome species. Their floral characters have a remarkable similarity to those of the *Metrosideros*, differing from them only in length and colour. *C. rigidum* is a fine plant, of which a huge specimen is in the temperate house at Kew, and which produces large, brightly coloured whorls of flowers every year. *C. speciosum*, *C. lanceolatum*, and *C. salignum* are other cultivated kinds. Several *Melaleucas* were once grown, but as they appear to be lost altogether from gardens, they need not be dwelt upon here.

THE CULTIVATION of the plants just mentioned is within the power of everyone possessing a greenhouse. They require peat or a mixture of peat and loam with plenty of sand, and should be watered and syringed freely during the time when they are making their growth. In autumn they should be placed out of doors to ripen their wood, and during cold weather protection from frost is all they require to keep them in health. To induce these plants to grow into shapely specimens, the growths should have their tips pinched directly on reaching their full length. B.

Narcissus cernuus.—The name *cernuus* was not, I think, intended to apply exclusively to any particular white Daffodil. It means pendulous—nodding—and this feature applies to all the white Daffodils. The *cernuus* of Burbidge, plate 8, is certainly not that figured by "Veronica" (p. 377), which also differs materially from plate 924 of Curtis, "*Narcissus moschatatus* (a), the white long-flowered Daffodil," which is there synonymous with *N. cernuus*." According to Burbidge, the difference between *moschatatus* and *cernuus* appears to consist in the primrose-yellow tube of the former, and the variety supplied by Mr. Barr as *moschatatus* has this coloured tube, whereas in *cernuus* the tube and perianth segments are greenish white. In all the plates, however, the

tube and perianth segments are about equal in length, but in "*Veronica*'s" woodcut the tube is shown considerably longer. Mr. Barr exhibited the same flower at South Kensington the other day as *cernuus*, and he had *tortuosus* there also with perianth segments as long as the tube. When I named this to him the day following he at once said that *tortuosus* should have the corolla shorter than the tube, and the two sorts are thus mixed in his nomenclature. "*Veronica*" says that Mr. Barr knows this variety as the Irish *N. cernuus*, but it is clearly more like *N. tortuosus*. The perianth segments become twisted after the plant has been a day or two in flower, or in hot sunshine. WM. BROCKBANK.

SEASONABLE WORK.

FLOWER GARDEN.

FLOWERING TREES AND SHRUBS.—Notwithstanding the coldness of the weather, these are this year very floriferous, and by way of memoranda for future planting, the present is the time to decide the merits of each, both as to the position for which they are best suited and the colour of the blossom. The wild Cherries, the Almonds, and Laburnums are all excellent for planting as standards in large shrubberies for distant effect; and the double and single blossomed Gorse, Broom, both white and yellow flowered, Lilacs, Syringas, and Weigelas are suitable for forming groups, either alone or in combination, but Syringas and Weigelas look best when well backed up with evergreen shrubs. Horse and Spanish Chestnuts, False Acacias, and Hawthorns seem most at home perhaps when planted singly on the turf, but this is purely a matter of taste and the character of the ground formation to be planted, which obviously can only be satisfactorily decided on the spot. Be that as it may, every place having any pretensions to gardening should have a collection of flowering trees and shrubs; and now when they are in full beauty is the time to note and decide to what extent it may be desirable to use them.

ROCK GARDEN AND HARDY FERNERY.—Pick off seed vessels and decayed flowers from the earlier flowering plants, and keep the whole free from weeds. Couch Grass and Spargula are at this season very troublesome, and unless destroyed betimes quickly overrun the weaker growing plants. The dwarf Phloxes, Aubrietias, Myosotis, Omphalodes, and two or three varieties of Saxifrages are now finely in flower, but, handsome as they are, they should not be allowed to encroach on others, which, like weeds, they quickly do if permitted to grow unrestrictedly. Keep the walks free from weeds, but not too dressy; Moss-grown or heathy are the most appropriate. Formal walks or edgings do not harmonise well with the surrounding irregularities of a rock garden, but where these exist keep the edgings clipped and the walks hard and clean. Ferns from which the old fronds have not yet been removed should have that attention at once, and additional soil should be given to all that need it; transplanting, too, may yet be done. When there is not sufficient to well furnish the ground, plant at long distances, and fill the intervening spaces with the common Wood Mosses, Sedums, and Stonecrops. The common wild Hyacinths, Wood Anemones, Violets, Primroses, Snowdrops, and Daffodils are all in their season most effective as undergrowths for Ferns.

GENERAL WORK.—Lawns should be mown and Grass verges clipped. Apart from the untidy aspect of uncut edgings, it is desirable to cut these regularly to prevent seedling Grasses making weedy walks, and the same remark applies to Grass margins of shrubby clumps. Continue to plant out all the hardy section of bedding plants, also thin out hardy annuals sown in the open borders, and plant out those sown in warmth. Stake Sweet Peas and make another sowing. Place in sheltered positions, easy of protection, out of doors all the hardest kinds of bedding plants, such as Pelargoniums, Ageratums, Lobelias, Verbenas, &c., which

will allow of the potting on of recently struck plants of the same kinds, and also the tender sorts, such as Coleus, Amarantus, Iresines, and seedling sub-tropicals, which, to do them justice, require plenty of space and warmth.

INDOOR PLANTS.

SHRUBBY CLERODENDRONS.—Old plants of these, such as *C. fallax*, *C. Kämpferi*, and *C. fragrans*, started early will now be pushing up their flower-stems, and should have their heads kept well up to the glass near the roof ventilators, as, although they like a brisk heat and a moist atmosphere, they do best where subjected to less shade and more under the influence of a considerable amount of air for a time daily than most things. For ordinary decoration *C. fallax* and *C. Kämpferi* are the most useful the first year of blooming after being raised from either seeds or cuttings; these, with their large, single, erect panicles of the brightest red flowers issuing from broad, massive foliage, have a telling effect interspersed amongst Caladiums and other fine-foliaged subjects. Keep the undersides of the leaves regularly syringed to preserve them from insects, especially thrips and red spider.

THUNBERGIA HARRISI.—Plants of this that have been blooming throughout the winter should now be cut back; they are free rooters, soon exhausting the soil. If planted out, as much of the top soil as can be got away without too great a disturbance of the roots should be removed and replaced with new material; if in pots, they ought to be partially shaken out and repotted, giving them more room. This *Thunbergia* does not require the warmest stove treatment, as if kept too close and hot it is apt to run over much into growth at the expense of flower, and it is not suitable for training as a specimen; it both does and looks much better when trained to the roof. Its pale lilac or mauve flowers, in form and size not unlike those of the major variety of *Achimenes patens*, produced freely during winter and spring, do much to embellish any house in which they may be grown, but they are not the best for cutting, as they soon flag when severed from the plant.

APHELANDRAS.—Large plants of the useful autumn-blooming *A. cristata* kept cool through the winter and started some time back should, if not already done, be now partially shaken out, replacing the old effete soil with good loam to which has been added a moderate quantity of rotten manure and sand. Large plants require large pots, or the bloom will be comparatively meagre. A moderate heat is sufficient with plenty of air and a liberal supply of water when growth has fairly started. *A. elegans* is a handsome free-flowering kind that needs comparatively little room, and should be found wherever stove plants are cultivated. Small plants of it should now be pushed on by giving them larger pots and encouraging free growth. Like most of the genus, it is an erect grower naturally, and can only be induced to branch out sparingly by stopping, yet the points should be once at least nipped out. *A. Roezli* is a small-habited species, and will bloom freely in little pots. Than this few more effective plants have been introduced of late years, its brilliant orange-scarlet spikes being often produced by examples in 4-inch or 5-inch pots. It is most useful for standing on the side stages of an ordinary stove.

SHADING.—Position and other local circumstances go to determine how soon in the year it becomes necessary to shade stove plants. A hip-roofed or lean-to house facing the south naturally requires the use of shade sooner than a span-roofed structure standing with its ends north and south, a position in which the bars and rafters do much to break the sun's rays when most powerful; no more shade should on any account ever be used than is absolutely necessary to prevent the foliage of the plants from being injured. Soft foliage, the result of indifferent cultivation, is much more susceptible of injury from direct exposure to the sun than that of the same plants would be if well managed. All sorts of makeshifts are often used

for shading, from the colouring laid on the glass down to flour-paste and whitewash; all these are objectionable, and the further the obscuring material is from white the more is it undesirable. Where a high standard of cultivation is aimed at, nothing but blinds on rollers will suffice, the material used being no thicker than will break the sun's rays without excluding them.

FRUIT.

VINES.—Take advantage of every ray of sunshine in the management of late houses by closing about 3.30 with moisture, when the fire-heat may be kept shut off until the temperature falls to within 5° of the night heat, which need not exceed 60° for the present. If inside borders are well drained they may be copiously watered without fear of injury; indeed, a large percentage of inside borders never get half enough water; the roots go out in search of that which is denied to them at home, and many people imagine it is the position of the border and not their own bad treatment which drives them downwards and outwards, often into deep subsoils too crude and cold for anything less hardy than a common Oak. Another mistake which many people make is the giving their late Vines too much root room, particularly in low damp situations where everything but the moisture-laden atmosphere is unfavourable to good Grape growing. In such situations we have always found that internal borders 6 feet wide, and external borders 9 feet wide, will give a maximum of good Grapes at a minimum of cost, simply because they are full of active roots which can be fed without watering half the garden, and being warm the Grapes invariably set, swell, and colour well. Another advantage is the alternate system of taking out and renovating the borders with new soil without having to sacrifice a crop, when too much vigour is unfavourable to the proper ripening of the wood, and as the latter means unripe Grapes, growers of late kinds who complained so much last winter will do well to look to their borders, and if they are wide, deep, rich, and cold, steel forks must be brought into use before they will again be successful in the Grape room.

Early houses in which the Grapes are ripening may have more air on fine days, but draughts must be avoided, and if the inside borders are sufficiently moist the usual damping down may be continued, as spring Grapes require more moisture than can be given to late ones. Let laterals grow without a check if they seem inclined to start, and keep a sharp eye on the old foliage, as spider is almost sure to be present, and injury to the primary leaves at this early season is very often the cause of early Vines breaking prematurely in the autumn, and covering their unfortunate owners with glory by ripening up new Grapes in January. With many the usual remedy for spider is flowers of sulphur, but, independently of the fact that Frontignans and other thin-skinned kinds are often rusted and ruined by its use, timely sponging of the upper and undersides of the leaves with soapy water is undoubtedly the most effectual, as it is the most economical mode of dealing with this troublesome pest. Another troublesome marauder is red spider, as it thoroughly enjoys the dry warmth and security which it finds on a bunch of Grapes, but it must be destroyed, otherwise the delicate bloom will be disturbed before it is properly set.

PEACHES AND NECTARINES.—Assuming that the final thinning of the fruit in the early house has been brought to a close, and the shoots have been properly regulated, give every Peach the full benefit of sun and light by elevating it above the foliage and pinch the points out of the strongest growths where their vigour is likely to detract from the size of the fruit when ripe. Feed well with warm liquid and syringe freely with soft water twice a day until the fruit begins to ripen, the first time before the ventilators are opened, and again after they are closed, when with sun heat the temperature may run up to 75°, and gradually descend to 60° for the night when mild, and 55° when cold, and sharp firing is needed to

admit of a little front air. Ply the syringe well in succession houses in which the fruit is stoning, mulch the borders with good rotten manure to keep in surface moisture, and feed with warm diluted liquid at every watering, or guano water where the growths are weak and the foliage is deficient in size and substance. Open the ventilators early on fine mornings, and increase the air as the temperature rises to 70°, reduce in a similar way, and close about 4 p.m. with a good syringing. Continue to disbud the shoots and thin the fruit in late succession houses, leaving a small percentage to be taken off at the final thinning. Heel in the young growths as they advance, lay in no more wood than is actually required for the production of the next year's crop of fruit. Fumigate on the first appearance of green fly, and encourage a short-jointed, vigorous growth by the free admission of air and timely closing to save fire heat.

PINES.—Early started Queens now swelling freely may be kept at a temperature of 70° by night and 80° through the day, with a rise of 10° more after shutting up with sun-heat and moisture. With increased light and sunshine the syringe may be used more freely, care being taken that an excess of moisture does not accumulate in the axils of the leaves, and so produce a crop of troublesome suckers. The plants will now require careful attention in the way of feeding as often as water can be given to the roots. As a rule, Pine plants receive more water than is good for them, particularly where they are loosely potted in large pots, and bottom-heat is obtained from fomenting materials only. Where fire-heat is used there is less danger, but in all cases a moderately moist growing state of the soil should be the aim. Good diluted liquid from the tank is not easily surpassed for general watering, and it is rendered more valuable when used alternately with soot or guano water. All stimulants should be weak rather than strong, perfectly clear, and a few degrees warmer than the house when used.

SUCCESSIONS.—If, owing to the severity of the past spring, the general stock of summer fruiterers show a greater inclination to grow than throw up fruit, increase the temperature, reduce atmospheric moisture, and keep them moderately supplied with water for a time. The majority of the plants will make a growth before they fruit, and unless there is likely to be a scarcity of ripe Pines at any particular time, it is best to let well-ripened plants take the usual course. Look over the earliest potted stock now rooting freely. Give more light and air. Keep the atmosphere moist, and syringe overhead after closing on bright days.

STRAWBERRIES.—If possible, remove all pot plants from houses in which Peaches, Grapes, or other subjects liable to be permanently injured by red spider are growing. Good pits heated with hot water, in which the plants can have full exposure to light, answer best. Syringe copiously twice a day at all times when not in flower. Feed well with good liquid until the fruit begins to colour, when clear water will be most suitable, and remove to an airy, temperate house a few days before wanted for use. The finest late kinds will now be well advanced, and as these will, under judicious management, lead up to early crops in the open air, insure quality by thinning off the weak blossoms before they open. A good batch of President, Paxton, or other favourite kind plunged in a cold pit, where the lights can be thrown off on fine days, will give pounds of fruit at a most acceptable time where December-started plants give ounces.

MELONS.—Having removed all surplus fruit from the early pot Melons, support those left on small pieces of board suspended from the trellis. Top-dress with strong loam and rotten manure, and water freely with warm liquid or guano water. Carefully preserve all old leaves from the base upwards. Syringe copiously after closing for the day, and run up to 90° with sun-heat. Plants growing on hills train regularly, stop when the vines have covered two-thirds of the trellis, and impregnate all female flowers as they open. Aim at a bottom-heat of 80°, and keep the roots on the dry

side until the fruits begin to swell, when more moisture and additional top-dressing may be given.

PITS AND FRAMES.—Plants in pits and frames will require constant care and attention to linings and covering, otherwise they will receive a check and become a prey to insects. Keep the young Vines and foliage thin, and remove all male and female blossoms until sufficient for a full "set" has been secured. Impregnate on fine days, and allow the surface of the bed to become dry during the process. Collect all waste material from Seakale beds, add a little fresh manure, and when in a fermenting state renovate beds from which Carrots and Potatoes have been removed. Form the hills at once, have strong, healthy plants ready, and turn them out as soon as the soil becomes warm. Make frequent sowings for future use, and throw away pot-bound plants before they become infested with spider.

ORCHARD HOUSE.—The fruit in the forcing house will now be stoning and apparently at a stand, as there will be but little outward difference for five or six weeks; but when this trying process is complete the change will be rapid, and more heat may be given if absolutely necessary. If time is not an object a temperature ranging from 55° to 58° at night, and 65° to 68° by day—with, of course, a few more degrees after closing—with sun will give the finest Peaches without distressing the trees. Guard against over-cropping as a very serious evil, always leaving the finest and best-placed fruit to ripen. Stop all strong growths to increase the size, and remove laterals to let in light and air. If the house is quite closed at night it should be well syringed and opened about seven in the morning, gradually reduced after two o'clock, and finally shut about half-past three, with another good syringing. A plentiful supply of moisture will now be needed, but an excess, particularly by night or with a low temperature, will soon destroy the flavour of the fruit. The water used for syringing should be free from lime, and the liquid given to the roots clear, generous, and a few degrees warmer than the mean of the house.

SUCCESSIONS.—As soon as the fruit is safe syringe twice a day when fine, and see that the roots are regularly supplied with water. Disbud and shorten back to a good shoot above the requisite number of fruit, and pinch the points out of strong growths before they have time to derange the balance of the sap. Give Cherries, Plums, and Pears the most airy part of the house. Syringe well, ventilate freely, and fumigate with Tobacco paper on the first appearance of green fly. Strawberries on shelves will take an abundance of water to prevent the balls from shrinking away from the sides of the pots. Avoid the use of saucers, syringe copiously, thin the fruit when set, and feed with good liquid manure. Keep a sharp look-out for grubs, which may be expected to appear on Plums and Cherries, and hand-pick before they have time to perforate the fruit.

HARDY FRUITS.—If retarded growth is the fore-runner of a good crop of fruit, the present season should give satisfaction. Stone fruit prospects in this locality are not, however, so promising as was at one time anticipated. The blossom buds on Apricots were extremely thin, and Peaches which made a bad start last spring, although now well furnished with good wood, are not over-stocked with flower-buds. Still, if perfect, these may be sufficient to admit of a little thinning. Cherries are abundantly furnished, and Plums may be a moderate crop, but I do not anticipate a glut from trees in late, damp situations. The most important work in this department will have been for some time the protection of blossoms and embryo fruit from frost by the application of the most available kind of shelter. In early gardens safe from frost young growths may have felt the effects of the scathing east winds if they are not already well stocked with red spider. Where this is the case timely attention to the preparation and application of insecticides is of importance, but it must be borne in mind that at this early season weak applications can only be applied with safety. For general use

the old-fashioned wash of soft soap, sulphur, and tobacco water is not to be despised, as it is safe, easily applied, and within the reach of all. Look well to newly planted and root-pruned trees. It is not necessary to saturate the ground with cold water, but a good moist mulching and an occasional dash with the syringe will help them through this trying spring. Look over old Strawberry beds, remove troublesome weeds, which often get established in the stools, and at the same time work in the winter mulching as a protection and stimulant to the young surface roots now starting into growth. New beds may now be made where plants have been kept for that purpose. Make them deep, rich, and solid, use fresh virgin loam for planting with, mulch and water.

CUCUMBERS.—As few plants give a better return than the Cucumber, it is too often the practice to allow the plants to exhaust themselves, and so become a prey to insects at a time when good fruit for private use is of the greatest value. Where old plants can be dispensed with, a heavy flush may be taken prior to taking them away; but if it is necessary to retain them, light cropping is of the greatest importance. Established plants will now take more water at the root, heavier syringing, and the compost used for top-dressing may be heavier than that used through the winter; keep the foliage thin and clear of insects by the application of the usual remedies, and lower the trellis a few inches to prevent it from touching the glass now growth is becoming luxuriant. Ventilate without producing a draught, close at 80° to 85°, run up to 95°, and avoid shading. Continue treatment recommended for frames, renovate linings alternately, cover with dry mats, earth up with rich turfy loam, and keep the young growths thin and free from insects by good cultivation and the maintenance of a steady heat. Make a good sowing of Smith's Frame for planting after forced vegetables. Prepare beds for ridge kinds and plant under cap glasses.

KITCHEN GARDEN.

BRUSSELS SPROUTS should now in most places be ready for pricking out. Get a load or two of old Mushroom manure, spread it on the surface of any out-of-the-way corner (1 inch deep is ample), and finish off with another inch deep of fine soil. Burnt refuse is the best of all mixtures for young plants, say four barrow-loads of soil to one of refuse; on this prick out the young plants 4 inches apart, and when planting out finally force the spade under the bottom of the bed, and each plant will come up with a ball. Set your line across the site to be planted, and take out one side spit, and at every 3 feet apart lay in your plant, pressing the soil firmly round it. Nothing more is needed except keeping the ground free from weeds. Spring Broccoli should now be sown in most parts of the country. We sow in drills 1 ft. apart, and plant out the plants from the seed beds to their permanent quarters, the site being that occupied by early Potatoes. When the Potatoes are all lifted we give the land a rough rake over with an implement called the agitator, set the line across the site, and make the holes with a crowbar; one man drops in the plants while another fills the holes with water. The work of planting is then complete. Of all winter Broccoli we have ever seen we pronounce Snow's (when true) to be the very best. The first to make its appearance with us this season is one sent for trial called Hosking's Broccoli, a most useful addition, growing compact and dwarf, followed by those two really fine varieties Leamington and Watts', both too well known to require further remark. For the latest we find Burghley Champion and Cattell's Eclipse to be the very best. We have the two latter now coming into use. Keep plenty of Lettuces tied up for blanching. Black-seeded hardy Cos is the thing to grow for the winter. In these Lettuces one finds something crisp and good, but French Cos Lettuces grown under cloches are soft, like tissue paper compared with brown paper as regards thickness and substance of leaf. They are really handsome Lettuces, but never did the old proverb, "Beauty is but

skin deep," apply better than in the case of these French Lettuces.

PROPAGATING.

ALL soft-wooded subjects, such as Bouvardias, Fuchsias, and Heliotropes, kept during winter in a semi-dormant condition should now have increased heat and moisture. In repotting, remove as much of the old soil as can be done without injury, and use only pots large enough to hold the roots without inconvenience. Soil of a moderately light texture tends to encourage quick root growth. Avoid using any stimulating manure for plants that are required for propagating, as although fine-looking cuttings may be the result, they will turn black and absolutely refuse to root, that is if strong manure be used. Another point needing attention is to make the cuttings wholly of young growth; on no account leave a base or heel of old wood; indeed, where every cutting is an object the better way is, in taking them, to cut them off above the bottom joint, thereby leaving one eye of the new growth on the plant. As the base of the cutting need not be a joint, it may be cut off immediately above the bottom joint, and the bare portion of stem below the bottom leaves will serve as the part to be buried in the ground without removing any more of the foliage. Soft succulent cuttings, such as are produced in spring, should never be put firmly in the soil; on the contrary, the cutting-pots must be lightly prepared, indeed so lightly that the cuttings can be stuck in without a dibber. This remark applies only to places in which they can be kept close, as if cuttings have to stand in a house and take their chance with ordinary subjects they require to be put in more firmly. Any light soil makes a good rooting medium; even pure sand or Cocoa-nut refuse may be used, but in these it is necessary to pot off the cuttings as soon as rooted. In raising Cannas from seed it is at best a risky practice to cut or file the seeds to hasten germination; if soaked in warm water for a few days the same end is attained without any fear of damaging the germ, unless the water is allowed to evaporate and leave the seeds dry just as they are starting. This may easily happen, as if placed in pans and set on hot-water pipes evaporation is very rapid. New varieties of Chrysanthemums, Phloxes, and Pentstemons obtained in the spring in the form of small plants will, if placed in gentle heat, grow away at once, when the young growths may be taken off and treated as soft-wooded cuttings. Taberous Begonias required for stock, if started now in the same way as Dahlias are done, will yield a good many cuttings, and where seedlings are raised no time should be lost in sowing the seed. Sow in light soil thinly, and do not cover except with a pane of glass. As soon as the seed germinates the glass must be removed, and the pots or pans kept in a light, but warm position to prevent damp.

CORREAS.—These pretty winter flowering shrubs make effective greenhouse plants even in a small state, and their propagation is not a difficult matter. Make cuttings of the young shoots when half ripened. As a rule four leaves will be enough to leave on the cutting, so in removing it from the plant cut immediately below the third pair, then cut off these two bottom leaves, and the cutting will be ready for insertion. Choose medium or weak shoots for cuttings rather than strong ones, which are far more liable to decay. If to be placed in a small frame within the propagating house, 4-inch pots will be a convenient size, but if bell-glasses are to be used of course the pots must be chosen to suit the size of the glasses. Fill the pots to within 1½ inches or 2 inches of the rim with broken crocks, the upper layer being crushed finely to prevent the soil from being washed down through the interstices. When this is done fill them to just below the rim with soil consisting of peat and sand sifted fine and pressed down firmly, then finish off with a thin layer of pure sand. Give each pot a watering through a fine rose, and let them stand an hour or two before using them. Then insert the cuttings as thickly as possible without over-crowding, bearing in mind that cuttings

which touch the sides of the pots generally root before those in the middle. When small pots are used this can be carried out, but where bell-glasses are employed the cuttings must not be brought near enough to the edge to interfere with the removal or replacing of the glasses. Put the cuttings in firmly, and when each pot is finished give a thorough watering to settle every cutting in its place. The most suitable temperature is one a few degrees higher than that in which the plants from which the cuttings have been taken have been grown—say that of an intermediate house, as if too great a change takes place in this respect the cuttings often speedily decay while a few degrees higher than they are accustomed to will hasten their rooting.

JAPANESE PRIVET AND GARRYA ELLIPTICA.—Cuttings of these should be taken towards the end of summer when the young shoots are about half ripened, and kept close in a cold frame till rooted. They should consist wholly of the current year's growth with just sufficient leaves removed for purposes of insertion, but no more. Get some 6-inch pots, drain them well, and fill them with sandy soil pressed down rather firmly, then insert about a dozen cuttings in each pot, give a thorough watering, and the operation is complete. In this way many of the cuttings will root during the autumn, and the others will do so very early in spring, when they may be potted or planted out, but the better plan is to pot them in small pots till established, then plant in the open ground. They may also be put in now, when they will root during the summer, but they will require keeping close and shaded till that takes place. If put in the open ground a sheltered spot should be chosen for them, and the cuttings should be made longer than for pots.

KITCHEN GARDEN.

CULTURE OF RUNNER BEANS.

I MAY safely premise that no vegetable more eminently combines the ornamental with the useful than the Scarlet Runner, and that few are so profitable and generally popular. At the same time I should like to see its culture still more extended among the proprietors of villa and suburban gardens if only for decorative purposes, such, for instance, as covering archways, porticoes, or wherever climbers are required, provided always the positions are warm and sunny. Scarlet Runners grow rapidly, require but little training, and their large and prominently disposed spikes of scarlet, white, or speckled blooms, as the case may be, are borne in profusion till cut down by frosts; while the blooms, provided liberal treatment is given, will be succeeded by clusters of pods, which are very acceptable in most establishments. A row may also be grown in connection with the flower garden, the running growth in this instance being stopped near the ground or at any height. For comparatively small establishments long rows of plants are not needed to maintain the supply of pods for the kitchen; on the contrary, a few isolated plants, say oppositely in pairs at intervals along the borders of the principal garden walks, will be sufficient; plants trained to tall, strong stakes will generally yield a surprising quantity of Beans, and, in addition, are highly ornamental. In fact, this is one of the best methods of growing Scarlet Runners, especially where space is limited, the single pillars not greatly interfering with the neighbouring crops, besides proving more productive than is the case where either the rows or plants are crowded. If rows are preferred, these in common with Peas may well be disposed next the pathways, thereby assuring them abundance of room and light without detriment to other crops adjoining, or rather on the garden side. Where the

DEMANDS OF LARGER ESTABLISHMENTS have to be anticipated and a different class of garden has to be dealt with, several rows of Beans have to be grown. Probably the majority of those in charge of these gardens require no advice upon the subject, but I may yet safely assert that

Runner Bean culture is far from being generally intelligently practised. As a rule the plants are grown too thickly, the result being light crops and, during dry seasons especially, of short duration. The ordinary method of sowing is in double rows, these being about 12 inches apart, and the seed frequently a less distance asunder, nearly every plant receiving a stake so disposed as to cross near the points, girding stakes connecting the whole. This I consider to be a mistake, the practice involving much unnecessary expenditure in the shape of labour and stakes. Our plan, which I believe to be much more profitable, is to grow them in single rows 6 feet apart, the seeds being sown 4 inches to 6 inches apart according to its quality, and eventually thinned out or made good by transplanting, so as to bring those retained about 12 inches asunder. To each plant a strong straight stake is given, these being when inserted from 6 feet to 7 feet high, and all are laced together with more stakes in a line 12 inches from the top—these serving to steady the whole. Between these rows we sometimes grow two rows of early Potatoes, but should the ground be too heavy for these, we grow two or more rows of early Cabbages or Cauliflowers. As I have previously observed in the case of Peas, Runner Beans may be

GROWN WITHOUT STAKES, and in some districts in the counties near the metropolis fields comprising many acres are devoted by nearly every grower to their culture. In their case I may add that the crops are to a certain extent speculative, their culture being necessarily expensive. For instance, I have known fields of Beans sold early in the season to speculating buyers—who relieve the grower of all further trouble connected with picking and marketing the Beans—at the rate of £22 per acre, and yet prove a capital investment, while perhaps the next season when Beans are very plentiful they scarcely realise enough to pay expenses. In small gardens, or where stakes are not available, the field plan may be advantageously adopted, and it is also the best for securing an extra early supply. The rows may be disposed 3 feet apart, and the plants eventually 12 inches to 15 inches asunder. Instead of encouraging the running growths, these should be kept closely stopped. If this precaution is neglected the Beans get smothered with growth, and in this state are both unsightly and unproductive. Stopping induces the early and continuous formation of large erect spikes of bloom, followed by great handfuls of pods. As the latter are naturally heavy, they rest on the ground, and in wet weather get rather dirty. For the markets they have to be washed in tubs of water, but in private gardens the washing may be avoided by giving the plants a mulching of fresh stable manure, this serving to keep the pods clean, as well as preserving moisture about the roots. Runner Beans require and deserve

LIBERAL TREATMENT, in the shape of trenched or deeply dug ground and abundance of good manure. Narrow, Celery-like trenches I do not recommend, ours being about 3 feet wide and two spits deep; in fact, prepared as recommended for Peas on p. 274 of the present volume of THE GARDEN. They require abundance of moisture at the roots, and an occasional or frequent supply of any liquid manure available will materially benefit them. Ours do not get much of the latter, but what little we are able to secure is given either during showery weather or subsequent to a soaking with clear, soft water. If watering is resorted to during dry weather, and this is absolutely necessary where the ground is shallow and resting perhaps on a gravelly subsoil, or where the ground has not been heavily manured and deeply dug, thorough soakings should be given, and that before the soil has become very dry. Dribblers are of no avail. It is also advisable to mulch heavily either with rough manure or Grass from the mowing machine. We usually sow the seed during the last week in April or early in May, and find a second sowing by way of succession unnecessary. Where no extra pains, however, are taken in preparing the grounds, or other cultural details are neglected, the earliest sown may fail early in the

season, and in anticipation of this it will be advisable to sow again early in June. The stakes employed may be of any length, or from 3 feet to 9 feet, but in every case they should be inserted early, and the running growth should be constantly stopped when the tops are reached, or otherwise they become top-heavy, and in this state do not crop so evenly or heavily as may be desirable. The pods ought to be kept regularly gathered whether required for consumption or not, as if allowed to hang and perfect the seeds the cropping capabilities of the plants are greatly impaired. If seed is required, instead of allowing each plant to perfect a few, it will be found a better plan to devote a few plants, according to the quantity required, entirely to the production of seed. The best variety, all things considered, is the old Dutch Scarlet Runner; this is more productive than the larger Champion Runner, and also realises higher prices in the markets. Sutton's Giant White produces abundance of long, handsome pods, and these, besides being of good quality, are particularly well adapted for exhibition purposes. I ought, perhaps, to mention that Beans transplant readily, and may be sown in boxes and planted out should frosts or slugs and other enemies interfere with those sown in the ordinary way.

GROWER AND EXHIBITOR.

LATE PEAS.

LIKE "J. C. F." (p. 363), I do not believe in early Peas for late sowing, as I have never yet found them to be better than others, and after Marrows no one cares for them. It is not long since I read an article on Peas, written by a well-known authority, in which he stated that if asked his opinion as to the best kind, he should say the Ne Plus Ultra, and if he were questioned as to the second best, his answer would be Ne Plus Utra, and the same again for the third, and really I do not think he would be far wrong. "J. C. F." evidently holds the same opinion. Well, Ne Plus Ultra deserves all "J. C. F." says of it, but I should like to say a word in favour of the British Queen, which, if not equal or superior to Ne Plus Ultra, will run it pretty closely. Although perhaps the Queen may not be quite so good in colour, the Peas are tender and marrowy and very fine in flavour. What, however, I like the Queen for is late cropping, and as it is well to have two strings to one's bow, it is advisable to have two sorts of Peas for autumn. I always depend on the last named and Ne Plus Ultra for gathering at that time, as it often happens that the one escapes mildew better than the other, or lasts longer in bearing. The Queen is a robust branching kind, and sets its flowers and swells its pods very late in the season, and we generally have Peas from it here till they are killed or spoiled by the frosts. To have this or any other sort really late, or even in quantity during the summer, they must have good ground and special cultivation, or dry, hot weather soon puts an end to their bearing. The way in which we manage, and it is a plan I can specially recommend, is to sow the rows at wide intervals and grow Celery between them. By doing this both crops are benefited, as the Peas get plenty of light and air, and the Celery enjoys for a time the partial shade which it needs. By following this course the Peas are sown in the old Celery trenches, or in others prepared by digging into them manure to a good depth and re-filling them to within an inch or two of the surface. By leaving them a little lower than the surrounding surface, water or liquid manure can be given more advantageously. The distance at which we have the rows of Peas apart is 10 feet, and during the summer they are kept mulched, to which I attach great importance; the mulching shades the ground about the roots, thus keeping it uniformly cool and moist, and preventing cracking after water is given—a thing sure to occur without the covering. J. SHEPPARD.

Dwarf green curled Borecole.—We send you a sample of this useful vegetable. For twenty-eight days last month we had continuous frosts, varying from 7° to 25°. As a consequence, vege-

tation suffered dreadfully, most green material being cut off. These Kales were standing in an open quarter (intended for seed), and being so very dwarf and hardy, they have passed the ordeal wonderfully. In this respect, as well as their fine curl, we think them a very good type.—J. BACKHOUSE & SON. [Very good greens.]

Mushrooms out of doors.—I forward you a sample of Mushrooms grown out of doors at Aswarby. Our first bed was made up on January 23, spawned on the 26th, and soiled on the 29th of that month. We commenced gathering from the bed on March 15. Our second bed was made up on March 6, spawned on the 12th, and soiled on the 16th; we commenced gathering from it on April 23. Our beds are covered with good litter from the "crew" yards. This has been and still continues to be the finest Mushroom season both inside and outside of which I have any record. Many of the Mushrooms gathered weigh from a quarter to 1 lb.—RICHARD NISBET, Aswarby, Sleaford, Lincoln. [Large and succulent, well-flavoured Mushrooms, very different from the leathery, dusty things often sold in the market at this season.]

INDOOR GARDEN.

PRIMULA SIEBOLDI.

ONCE a year, and then only in a small way, do we hear anything about those lovely Japan Primroses which so fitly bear the name of Siebold. That not more is heard of them, or in praise of them, is doubtless due to the fact that so few grow, or know how to grow them. It would be incorrect to class these Primulas as hardy in the sense that they may be planted out in the open border and left to shift for themselves. They are so far hardy that ordinary frosts do not injure them, but they are harmed by excessive moisture, and outdoors want both a dry position and some shelter. But their chief charm, blooming, as they do, at a time when frosts and harsh east winds are apt to prevail, is when employed as greenhouse plants; and as such in pots, producing some half-dozen or more trusses of bloom, it is not easy to beat them for elegance or beauty. The stems are brittle, and the flowers somewhat fragile, but under glass and without heat graceful, and indeed lovely. I fear all who have obtained the home-raised kinds have failed to treat them so as to secure the best results. Briefly, I would say that, whilst the crowns should not be so crowded in the pots as to prevent full development, yet excessive root room is not desirable. I grow all my stock during the summer either in pans or 6-inch pots, where the rhizomes and foliage find ample room for development. Upon this free development depends the blooming capacity of the crowns the next season. After the best of the bloom is over in May all the plants are placed in a cold frame, where they are sheltered from hot suns and heavy rains; strong winds, too, are objectionable, and are not difficult to guard against. Granted these conditions, with careful attention in watering, and their culture for the summer is complete. Early in winter the pots are brought under cover, the roots turned out, and all the rhizomes picked out and broken up, the strongest being put on one side for potting singly in 3-inch pots, and the rest are repotted into 8-inch pots, to grow into stock for the following year. Of course, many of these latter bloom; but all those selected for potting singly will bloom freely. The roots like the early contact with the sides of the pots, which they soon feel when in such small ones, and invariably the growth so treated is stronger and the bloom finer and better coloured than is the case when the rhizomes are repotted at once into large pots. The great advantages which follow from the plan of potting the best crowns singly are, first, that for furnishing or ordinary decorative purposes they may be used anywhere and in many ways; and secondly, if required for exhibition, half-a-dozen of the best put into a 7-inch pot give a beautiful, even clump at once. All these single plants are, ere the summer comes, shifted into 8-inch pots for summer growth. The following are all good kinds, viz., laciniata, fringed,

dark red; rosea laciniata, fringed, pink; alba grandiflora, fine pure white; Ophelia, drooping lilac; Hermia, delicate mauve; and Mauve Beauty, tinted white. These are all free growers, though there are others equally beautiful. A. D.

TWO NEW DIEFFENBACHIAS.

As with Crotons, Dracænas, and Marantas, so with Dieffenbachias, there seems to be an inexhaustible supply of them, for each year brings us new kinds—some good, others inferior. The two new sorts, of which the annexed are illustrations, are both distinct and handsome, and both will in-

blended so harmoniously as to render the foliage very rich and attractive. Like all their congeners, these two are lovers of warmth and moisture, and are of easy culture in an ordinary stove, and being fast growers, soon become fine specimens.

DOUBLE IVY-LEAVED PELARGONIUMS.

Few plants are more popular than these, and few more useful. Besides being well fitted for growing into specimens of a pyramidal form, they make pretty bush plants in 6-inch pots if supported by a few sticks, and are in that form well adapted for the greenhouse, where they will flower

All the varieties just named have the true trailing habit of the old kinds rather than the stout sturdy growth of many recently introduced sorts. Others with the same habit as the old kinds are M. Dubus, bright carmine-pink; Rosina, pale pink; Mdle. Jeanne Wouters, deep rose; Robert Fortune, pale red; M. Pasteur, bright magenta; Comtesse Horace de Choiseul, bright pink, shaded towards the edges with magenta; Sidonie, deep mauve; and Gloire d'Orleans, crimson-magenta, the last one of the best. Strong stiffer growing varieties include Comte Horace de Choiseul, salmon-rose; Albert Crousse, light salmon; Mdme. Crousse, pale pink; Eurydice, rosy mauve; Mdme.

Dieffenbachia reginae.

vitably be prized by those who have a taste for beautiful foliaged plants. *D. reginae* is one of the newest additions. It was introduced from South America by Mr. Bull, of Chelsea, who is now distributing it. It has oblong elliptic leaves, rounded at the base, and almost wholly covered with greenish white, mottled with blotches of pale green, and a few streaky markings of a deeper shade, rendering the plant very effective. Another new Dieffenbachia named *Rex* is among the new plants offered this season by Mr. Bull, and is likewise handsome. *D. magnifica* has been introduced from Venezuela by the Compagnie Continentale d'Horticulture, in whose nursery at Ghent we saw it a short time since and were impressed by its beauty. The annexed engraving gives a good idea of the habit of the plant and the marking of the foliage, which is as large as that of any of the other species. The colour of the leaves is a clear green, spotted and mottled with pure white and various shades of green,

throughout the summer and well on into the autumn. The stronger varieties, again, if treated as greenhouse climbers in a sunny spot, especially where used to cover the end of a house, both grow and flower well. For balconies or vases, too, their procumbent habit thoroughly fits them. It is now some seven or eight years since *König Albert*, the first double kind, made its appearance. It has violet-mauve coloured flowers, and is still one of the best of that tint, but now there is a great range of colour among them. A good pure white is still, however, a desideratum, for though I have flowered *Gazelle*, *Finette*, *Madame E. Gallé*, and *Sarah Bernhardt*, none of them completely fulfilled my expectations as to purity of colour. The best I take to be *Madame E. Gallé*, a good and free kind, but with a slight blush tint in the blossoms. *Jeanne d'Arc*, sent out last autumn by Lemoine, I have not yet flowered, but, judging by the description given of it, it should be a good pure white.

Jules Menoreau, deep rose; *Mdme. Lemoine* rather brighter than the preceding, and moreover shaded with magenta; *M. Barrall*, deep blush; and *Anna Pfitzer*, salmon-pink. Although all named in the foregoing list are well worth growing, for a dozen I would select the following, viz., *Albert Crousse*, *Comte Horace de Choiseul*, *Comtesse Horace de Choiseul*, *Eurydice*, *Gloire d'Orleans*, *Mdme. Crousse*, *Mdme. Lemoine*, *Mdme. E. Gallé*, *Mdme. Jules Menoreau*, *Mdme. Jeanne Wouters*, *M. Dubus*, and *M. Barrall*. H. P.

Impatiens Sultani.—At present this Balsam is but little known, but when more widely distributed it will doubtless become popular. It is extremely floriferous, and its bright, rosy magenta-coloured blossoms supply a tint wanted amongst stove plants. My plants of this Balsam in an ordinary stove have flowered continuously from early autumn to the present time. Even rooted

cuttings produce blooms when only a few inches high. If kept too wet during winter the fleshy stem is sometimes apt to decay; but even if that happens the shoots can be utilised as cuttings.—H. P.

Clianthus puniceus.—This is a great favourite at Farnborough Grange. Plants of it from last year's cuttings have made growths from 2 feet to 3 feet long, and are literally loaded with bloom, the arching sprays of peculiarly shaped coral-red flowers associating well with plants of a more stiff and formal type.—C. S.

Begonia glaucophylla.—I saw the other day at Farnborough Grange a fine plant of this growing in a basket suspended from the roof of one of the plant houses. Its beautiful panicles of cinnamon-scarlet flowers, contrasting pleasingly with its fine dark glaucous foliage, entitle it to a foremost place among plants suitable for baskets either in conservatories or drawing-rooms.—C. S.

The watering of plants is a most important matter, and one which is too often overlooked. They should never be allowed to become too dry, and on the other hand if water is poured promiscuously into the pots without first ascertaining whether they require it or not, the results will be most unsatisfactory. To the inexperienced this will seem rather a difficult matter, yet it is one which must be surmounted; so many plants require more than ordinary care to grow them well, that the strictest rules must be observed. Plants should never be watered until they really require it, but this is such a delicate subject, that no very correct explanation can be offered concerning it. Careful watering does not mean that it should be given in dribblets, but enough should be given at a time to thoroughly moisten the whole of the soil. It should then be withheld until the soil has become dry again, never, however, allowing it to be so much so as to cause the plants to flag, conditions which can only be arrived at by careful attention and experience.—T. B., *Arbroath*.

Effects of hot water on plants.—I read in some of the papers lately about a Frenchman restoring the vigour of weakly pot plants by watering them with water at 140°. It was not with the idea of proving the value of this plan, which I doubted at the time, but to prove the reputed effects of hot water on insects, that I lately made the following experiment, which has had a rather singular and unexpected result, so far confirming the Frenchman's experience. Some six or seven weeks ago I dipped a narrow-leaved *Croton* in water at about 130° for about a minute or more, and afterwards set it in its place and waited the result. In twenty-four hours or less every leaf, embryo bud, and insect was quite dead. I expected the leaves to go, but not the numerous small buds that were showing on the stems. However, all were killed, and the plant itself seemed killed to the root for three weeks, when it began to push freely from the old wood all over, but the new leaves were not the leaves of *C. angustifolius*, but of the broad-leaved variegated *Croton*, only much greener and healthier than that variety usually is. The old dead leaves of *C. angustifolius* were still on the plant, white and bleached, and in this condition several of my neighbours saw it and were much struck at the metamorphosis. The true leaves of *C. angustifolius* are now coming again at the points of the shoots.—J. S. W.

Confervæ (C. E. F.).—I find, on further examination, that the papery substance you found on the tops of Rushes is composed of fibres of *Conferva crispata*. When alive each filament is hair-like and composed of a single row of cells placed end to end. When this plant is dried the walls or skin of the cells collapse and become flattened, but the partitions between them are more rigid, so that a dried filament, when magnified, presents much the same appearance as the top of a twisted paper spill when it has been pinched in and out. A mass of this plant remaining at the bottom of a pool which no longer contains water becomes flattened as it dries and withers, and the filaments, assuming the form just mentioned, are not easily

separated, and become matted together into the substance you forwarded.—G. S. S.

NOTES AND READINGS.

COLOURED SPRING FLOWERS.—Those who desire a scarlet or scarlet-crimson spring flower of the shade of *Vesuvius Pelargonium* and quite as vivid should plant the *Anemone fulgens*, which has been flowering freely in cold regions for some time back. It is a beautiful subject for rockeries or spring gardens. May I ask what has been the experience of those who have had this plant planted permanently out for some years? I regard *Narcissus Horsfieldi* as one of the best and prettiest of its class—compact habited, a free flowerer, with an orange cup and petals paler than the "pale Primrose," affording a rather striking and pleasing contrast. For a telling group of clear yellow, *N. maximus* (single) beats almost any other variety. Once the single varieties of the *Daffodils* become more familiar to gardeners, the double, and falsely so-called "incomparabilis," will dwindle in their estimation. The *Daffodil* presents us with the highest type of a beautiful single flower. For a variety of rich colours we must go to Dean's single *Primroses*, which will soon be wanted by the million, or I am mistaken. What a field the florist has missed here. They quite surpass the *Auricula* in all its aspects, and all are good—big, broad flowers, some nearly covering a crown-piece, hardy, early, profuse of flower, and long lasting. For a pure blue untainted by purple or red we have nothing so generally useful and pretty as the common *Grape Hyacinth*, nothing more hardy or sure. Its compact masses of miniature spikes are most effective. For a clear porcelain blue we have the lovely *Forget-me-not*, which is indispensable. The small and sweet *Myosotis rupicola* seems a doubtful grower notwithstanding its antecedents, but all the varieties are good, and the white form of *sylvatica* is very handsome and useful. For a dark crimson the common double *Daisy* must not be forgotten; it is as accommodating as it is pretty and telling in masses. Pale yellow and white flowers prevail in spring, but no difficulty need be found in securing plenty of colour in the spring garden by judicious selection and planting.

TWO BUNCHES OF GRAPES TO A LATERAL.—No one will "exclaim with horror," I imagine, as has been suggested in a contemporary, at the idea of leaving two bunches of *Grapes* on one lateral, because the thing is quite common, and on the very methodically trained *Vines* at *Thomery* it is the rule; but for all that we do not think many English *Grape* growers will adopt the practice. If leaving two bunches on one lateral necessitates smaller bunches and cutting the shoulders off those that are left, it looks very like robbing Peter to pay Paul. You cannot take more out of a *Vine* than is in it, and it matters little how the bunches are distributed; but most people think more of one four-pound bunch to one lateral than two two-pound ones from the same, because the first can only be had by higher culture. The "winging" of *Grape* bunches is no new idea. The late Mr. Tillery practised it, and was twitted about it by certain writers at the time.

PACKING GRAPES.—The same writer, who, by the way, knows better, advances as a plea for small bunches of *Grapes* that they pack and travel much better than large ones, and in consequence realise more money in the market. "Awkward" bunches four pounds weight and upwards are objectionable on that account, it is stated. When one remembers the grand bunches Mr. Meredith used to send in perfection everywhere, and beat everybody in prices, not to speak of the thousands of pounds weight sent from private gardens constantly, the above excuse for moderate bunches must amuse growers. Every man has a right to grow such examples as suits his purpose best, but it is hardly wise to assign reasons which gardeners know are not valid. Gardeners must be novices indeed if they

cannot pack large bunches, however awkwardly formed, above four pounds weight to carry by rail any distance in perfect condition. There are gardeners who send big bunches of *Grapes* in quantities from the borders of Devonshire to the Isle of Skye by rail, road, and boat, arriving at their destination without a bruise. Large bunches are just as well formed as small ones.

WHAT IS A CROP OF GRAPES?—Still quoting the same writer, whose accuracy is usually unimpeachable, we discover that what is described as an "amazing, astonishing, murderous" crop of *Grapes* is something under one pound to every two square feet of space, but which cannot surely be regarded as suicidal practice. We arrive at this result by the disenchanting process of multiplication of the areas given. No one can estimate a crop of *Grapes* by looking in at the door, nor yet by a nearer look. A valuer would not estimate things in that way, and it would really be better in many cases if crops of this kind were looked at with a valuer's eyes; it would be less misleading.

FLORISTS AND THEIR FOIBLES.—We read as follows in a contemporary:—

We are on the eve of the National *Auricula* and *Polyanthus* Show, and the season of these ancient and favourite florists' spring flowers is upon us, so that the minds of many who are novices in the florist's art will be exercised to find out to their own satisfaction wherein lie those points of excellence which make up the favoured flowers. None of these points are more difficult to appreciate than is the one that relates to the needful thrum centres, because those who care for a flower only for the general beauty it displays, or perchance the perfume it emits, entirely fail to understand why the florist should insist so strangely upon the value of thrum over pin eyes. But the florist proper has, in the course of his study of the properties of flowers, gone far beyond the popular estimate, and found beauties and charms where the common spectator or grower sees only generalities.

Truly ordinary admirers and lovers of God's gifts in the shape of flowers will "be exercised to find out" the points of excellence which make up the favoured flowers of the florist. To ordinary mortals what a blessing it is that the beauty of Nature's flowers is usually stamped on the face of them for bees and butterflies and men to see, for, according to the most recent revelations on this subject, it would appear that although human beings do possess highly sensitive nasal and visual organs as well as lofty and intelligent perceptions, Nature intended the bees, &c., to have precedence. What a world of beauty must be lost to those "who care for a flower only for the general beauty it displays and the perfume it emits," and cannot perceive the transcendental claims of the "needful thrum centres," nor the "value of thrum over pin eyes." We feel abased when we contemplate our appalling ignorance in this respect. "The colouring of a florist's *Polyanthus* is as clear and precisely marked as if it were done by a skilled artist." Think of that! Nature must be taking lessons at the Royal Academy. It is confessed, however, that she still persists in preferring "pins" to "thrums," notwithstanding all the florist has done to direct her in the right path. It is worthy of note also that the society which pursues these great ends is worthily styled "The National," because its members number very nearly half a dozen individuals. In the list of prize takers, Mr. A. follows Mr. B. in one class, and precedes him in another. In the next class this order is reversed, and so on to the end of the "nation." Alas, that such a nation should be doomed soon to become as extinct as the *Pterichthys* Milleri of the old Red Sandstone. Our florists of the future will be the Veitchs, Cannells, Wares, Brockbanks, Wolley Dods, and others who are not fettered by rules and antiquated notions.

EARLY PRUNING AND LATE FROSTS.—The past month of March will be a red-letter month in the gardener's calendar. The destruction among *Roses* has been great, and the autumn-pruned plants have been the main sufferers. The winter

having been mild, buds grew, and the shoots are now dead; no buds are left on plants that are alive, but if adventitious buds push later the bushes will probably be saved. On the other hand, plants that were not pruned till after the frost had their terminal buds killed, but those at the base of the shoots being dormant escaped, and are now pushing freely. Early or autumn pruning of tender shrubs has its advantages, but a pruned plant is always the first to suffer from frost when it is severe, and Roses are particularly sensitive. The question of early or late pruning is one, therefore, which every one must settle for himself once he understands the peculiarities of the climate he has to deal with.

RED COLOUR IN STEMS AND FOLIAGE.—In a late number of *THE GARDEN* the opinion is expressed that varieties having red colouring among their chlorophyll are harder than those which have none. It has been long known to gardeners that red Celery is hardiest, and hence it is oftenest planted for a late crop; it does not perish from frost or rot so soon as white Celery. Red-leaved Chinese Primroses, too, are hardiest and most easily raised, and this is the marked characteristic of many reddish-leaved plants, but whether it is the rule or not is another matter. The best and hardiest Christmas Rose we are acquainted with is a variety very common in Yorkshire, coming into flower at or near Christmas, and continuing till the end of February; it has leaves and flowers as like the St. Brigid's variety, as figured in *THE GARDEN*, as can be—large and pure white flowers, and clear, narrow, green leaves, and stalks with no red in them whatever. It is common in cottage gardens, and is found in the most exposed and lofty situations. The red granule theory does not apply, moreover, to Grapes, either as regards red leaves or red or black fruit, for the white kinds are equally vigorous and hardy with the black. Red Roses are not the hardiest. General Jacquemont is hardy, but not so hardy as the Gloire nor the white Ayrshire Roses, which stand our hardest winters when other varieties die. Red-leaved garnishing Kales, which have abundance of red blood in their veins, are not harder than the clear green curled German Kale, nor do they as a rule grow either so tall or strong when red predominates. What is the red colouring matter? Is it chlorophyll in another form only?

"TEMPERED" WATER.—A contrivance, now being brought out by Warner & Sons for "the even tempering of water" for drinking and other purposes seems worthy of notice here. Water in pumps, pipes, or cisterns near the surface of the ground, it is well known, is always nearly of the same temperature as the air, whatever that may be at the time. For drinking purposes it is too warm in summer and too cold in winter. For watering garden plants we do not complain of its temperature in summer, but during winter and spring the water in outdoor tanks and pipes is very often much too cold to be applied to the roots of plants, and injury is frequently done by its careless application. The new invention is designed to obviate this state of things. It consists in principle of a tube, the bottom end of which is sunk deep enough in the earth to be beyond the influence of surface cold or heat, and preserves the water at the natural temperature of the earth, perhaps at 50° or higher. The tube is filled from a reservoir on the surface; the pressure of the water in which, it appears, forces the bottom water up the pipe to the top, where it is drawn off, hence the tube is always full and the water ready for use. How far the contrivance can be made available for garden purposes we have yet to learn.

THE SCOTTISH HORTICULTURAL ASSOCIATION.—One of your contemporaries is responsible for the following account of this enterprising association: "The chairman, having started a discussion as to the meagre reports of the proceedings of the Society given in the Edinburgh papers, suggested that the conductors of these should be approached in the matter; several members urged

that the horticultural journals were even more blameworthy in this respect, and one of the speakers submitted that in the event of the Society's business not getting proper recognition in the acknowledged organ of the gardeners, it should be "boycotted," a statement which was loudly applauded." Eventually the matter was left in the hands of the Council." One cannot believe that any considerable number of the members applauded such a resolution, and I question now that the matter has been turned over to the Council if any more will be heard of it. The result of such a step would probably be that the association would "boycott" itself. The association may depend upon it that it is neither the desire nor the interest of any of the papers to overlook its doings and transactions worth recording; and it will probably not have escaped the notice of members that only one paper has taken notice of their bumptious resolution. While saying this, however, I have no doubt that many readers would be pleased to have a better record of Scottish horticulture, whether furnished by the Scottish association or any other body, but if the interest in general horticulture in Scotland is to be measured by the circulation of gardening papers in that country, we are constrained to believe that it is hardly equal to that shown by some single English counties. The very best thing which the Scottish Horticultural Association can do is to promote the cause of horticulture in Scotland by widening the scope of its interests and promoting the cause it has at heart, like the rest of us.

FREE GARDENING IN SCOTLAND.—To many English readers the term "free gardener" will be about as intelligible as "free kirk." I rejoice to see, however, that free gardening is assuming a new and better phase in the north than hitherto. Reports have been sent to me concerning the progress and doings of the association in Fife, Edinburgh, and Glasgow that seem to denote a revival of this ancient order under new and better auspices. At one time—not so long ago—the principal advantages of being a "brother gardener" consisted in the privilege of wearing a blue apron and of abusing and maltreating anyone else who attempted to don that badge without having gone through the preliminary barbarous rites in the nearest barn or other out-house which happened to be consecrated a lodge for the occasion. The brotherhood has now, however, apparently resolved itself into a friendly benefit society, and seems to be enrolling members at a rate which speaks well for its success, no fewer than 8000 members having been enrolled in Glasgow in recent years, "a number," the report says, "which was being increased at the rate of 1500 annually." We learn that there were free gardeners in Scotland when James VI. reigned, that the origin of the order is lost in antiquity, and that at the present time the order is more prosperous than ever, and boasts of 50,000 in Great Britain.

PEREGRINE.

Some plants at York.—Of *Chorispora Bungeana* we have over half-a-dozen good plants, three of which have flowered. *Hesperochiron californicus*, a plant which Mr. Baker tells me is from the Yosemite district, is very gay. Two plants of *Saxifraga cordifolia purpurascens* are blooming well. *Corydalis Ledebouriana* and *Primula poculiformis* and *Celmisia* are also well worthy of mention. I hope the last named one may flower. *Myosotidum nobile* has three flower-spikes which show the conical bud-heads; and we have also a true *Cistus ladaniferus* on which about forty flower buds are formed, so there is likely to be quite a treat in store for us. Two curious Primroses (*acaulis*) have come under my notice, and might be worth mentioning, as they serve to indicate the origin of corolla, &c. One of them was found wild in a wood by Mr. Draper, gardener to Marquis of Londonderry. Its corolla is formed of simple leaf lobes and the ovary is attenuated remarkably. One often sees Primroses with phyllod calyx, but a case like this is rare. The other instance is that in which two flowers had merged

into one, with two pistils and ovaries, ten stamens and divisions of the corolla, the tube having a central partition where the coalition occurred.—P. S.

RECENT PLANT PORTRAITS.

THE March number of Regel's *Gartenflora* contains

VIOLA PEDATA VAR. ATROPURPUREA.—A very pretty variety, the two upper petals of the flowers of which are deep purple and the three lower ones bluish white.

SAXIFRAGA RETUSA.—A small mossy growing Saxifrage, with pale pink flowers sometimes borne single and sometimes two on a stalk, but apparently never more than that number.

MAMMILLARIA SANGUINEA.—A curious pear-shaped Cactus covered with bunches of small spines and producing a crown of rosy purple flowers round its top.

The April number of *Revue de l'Horticulture Belge* figures

HELIOTROPE DORE ALBERT DELAUX.—A very pretty variety with evenly golden variegated foliage and fine large piped purple flowers borne freely in medium sized trusses.

The April number of *l'Illustration Horticole* contains

DIEFFENBACHIA MAGNIFICA (double plate No. 482).—A very handsome foliaged plant with large light green leaves profusely and evenly marbled with white. A native of Venezuela.

CAMELLIA MADAME LEMONNIER (plate 483).—A fine large flowered variety of very vigorous habit of growth, with fully double white flowers faintly flushed with rose colour. Raised by the well-known amateur florist at Lille, after whose wife it is named. From a seed produced by the beautiful striped variety *Lavinia Maggi*.

VANDA HOOKERIANA (plate 484).—An extremely beautiful Orchid, resembling the well-known *V. teres* in appearance and habit of growth, but with more pointed extremities to its leaves; the flowers are smaller, but more handsomely marked than those of the older variety.

The February number of *La Belgique Horticole* figures

VRIESIA BARILLETTI.—New species from the Equator; one-third the natural size. A curious variety, with small yellow flowers.

SCHLUMBERGERA MORRENIANA—A triple plate, showing entire plant, and also bloom spike in a more advanced state and with one expanded flower. This plant is also known as *Massangea Morreniana*, but the first name is considered to be its more correct appellation. It is a native of South America, and only a single plant of this handsome Bromeliad is known to be in cultivation in European gardens, belonging to M. Ferdinand Massange de Louvrex, who flowered it for the first time in October, 1882. It is a very handsome variety, with bright red flower-stem of great size and substance, attaining a height of between 4 feet and 5 feet, and crowned with a large bunch of delicate primrose-coloured flowers.

VAN HOUTTE'S Flore des Serres et Jardins de l'Europe.—The concluding number of the 23rd volume of this work contains coloured portraits of the following plants of a much more interesting character than those in the preceding numbers of this volume.

ANTHURIUM ANDEGAVENSE (double plate No. 2454-5).—This is described at length on page 368 of current volume of *THE GARDEN* with other interesting and beautiful hybrids of this brilliant and interesting family.

CYPELLA CERULEA (plate 2456).—A most beautiful, but unfortunately fugacious Irid, also known under the name of *Marica*, and already figured in the *Botanical Register*, the *Botanical Cabinet* (Loddiges'), Hooker's *Exotic Flora*, and Reichenbach's *Flora Exotica*. It opens its large and handsome bright blue flowers, which have a broad white stripe down the centre of each petal and a rosy brownish centre, in the early morning, and they close and fade shortly after noon, but quickly succeed one another on healthy, vigorous plants. It requires the temperature of a cool stove.

ONCIDIUM CUCULATUM (plate 2457).—A pretty Orchid with medium-sized flowers borne alternately on a spike, the three upper petals of which are brown with green tips and lip, and remainder of the flower white, beautifully and distinctly spotted with rosy purple.

LYSIONOTUS TERNIFOLIUS (double plate Nos. 2458-9).—A most beautiful and interesting Gesneriad from the East Indies, and belonging to the family of Cyrtandraceae. It has also been described by various botanical authorities under the following different names: *Chirita ternifolia*, *Lyssonotus serratus*, *Chirita polycarpa*, *Incarvillea dubia*, and *Calosacme polycarpa*. This delicately beautiful plant was introduced by chance to M. Van Houtte's establishment in the soil surrounding some other plants sent from the English colony of Belise, and produces bunches of tubular flowers borne on pendulous stems with four flowers at the end of each, and closely resembling in shape those of some of the Bignonias, the ground colour being white, most delicately veined and shaded with violet, with slight yellow veinings down the throat. The flowers seem to be produced in great abundance, and if of easy cultivation it may be considered a most desirable acquisition.

SANCHEZIA LONGIFLORA (plate 2460).—A reproduction of plate 5588 of *Botanical Magazine*.

DENDBOBIUM FARMERI VAR. ALBIFLORUM (plate 2461).—An Indian Orchid with rather insignificant white flowers.

DOUBLE-FLOWERED TUBEROUS BEGONIAS (double plate 2461-2).—A fine group of six varieties of these beautiful plants, all of them seedlings raised by M. Van Houtte. The four following varieties are not yet sent out, viz., *Mdme. Valerie Guequier*, *Princess Stephanie*, *Mdlle. Alice Guilmet*, and *Princess Clementine*, a fine pure white. The other two, *Mdlle. Jeanne Pecquereau*, double yellow, and *Mdlle. Bertha Frœbel*, were sent out in the autumn of 1880. No. 3 on the above list seems to be one of the very finest varieties that have been yet obtained; it is of immense size and substance, and of a pleasing shade of rose colour.

NERINE PUDICA (plate 2464) is a reproduction of plate 5901 of the *Botanical Magazine*.

ONCIDIUM PHYMATOCHILUM (plate 2465).—A rather prettily-marked, but small-flowered Orchid from Rio Janeiro, apparently drawn from a very poor and insufficiently-developed specimen.

RHODODENDRON DALHOUSIE VAR. VICTORIANUM (double plate 2466-7).—A most beautiful hybrid form of this beautiful greenhouse shrub, raised by M. V. Cuvelier, and having *R. Dalhousiae* and *R. Nuttalli* for its parents; it most resembles the latter in appearance of flower, but is smaller in size, and is said to possess all the great freedom of blooming of its other parent, so should be a decided acquisition to any collection of these lovely plants.

ROSE LENA TURNER (plate 2468).—A beautiful Hybrid Perpetual Rose raised by M. Verdier.

ODONTOGLOSSUM KRAMERI (plate 2469).—A reproduction of plate No. 5778 of *Botanical Magazine*, and not of plate 5578, as stated in acknowledgment of the loan in accompanying letterpress. A very pretty Orchid.

CAMELIA MADAME L. VAN HOUTTE (double plate 2470-1).—A very ordinary double pink-flowered variety.

ERANTHEMUM COOPERI (plate 2472).—A reproduction of plate 5167 of *Botanical Magazine*.

LELIA GRANDIS (plate 2473).—A handsome Brazilian Orchid with conspicuous flowers, of which the five guard petals are a golden brown and central tube pure white, prettily veined. It has also been described under the name of *Bletia grandis*.

ARUM DIOSCORIDIS (double plate 2474-5).—A truly hideous plant, hardly differing from the common wild *Arum* of the fields, and the reason for figuring which it is really hard to understand.

BOLBOPHYLLUM LEMNISECTUM (plate 2476).—A curious, but dull-coloured and insignificant little

Orchid from Moulmein, growing on the stem of a tree, and the flower-stems of which spring from singular green warty excrescences instead of the usual pseudo-bulbs.

AZALEA INDICA BARON N. DE ROTHSCHILD (double plate 2477-8).—A very handsome double purple self-coloured variety of these beautiful cool greenhouse shrubs, raised by M. Van Houtte.

CATTELEYA LUTEOLA (plate 2479).—A rather insignificant yellow-flowered epiphytal Orchid from Brazil.

POIRE BEURRE WAMBERCHIES (plate 2480).—A very late ripening variety of Pear seldom ready

invited to seats.—MARSHALL P. WILDER (President), *Boston, Mass.*

HEATING HOTHOUSES BY STEAM.

THIS is an important subject, and should be looked at without prejudice from the different points of view bearing upon it; but it is not new, as most likely many are aware. There are now at Cloughton Hall, near Preston, Lancashire, a range of five good-sized houses, built, so far as I can make out, towards the close of the last century, that were first heated by steam, but which was replaced by

Dieffenbachia magnifica (see p. 407).

for use before the month of May, and lasting in good condition till mid-June.

The April number of *Revue de l'Horticulture Belge* figures

ANTHURIUM GUSTAVI.—A handsome foliaged plant, said to have the largest leaves of any of its family, of a pleasing shade of green, distinctly veined with pale yellow. W. E. G.

American Pomological Society.—The nineteenth session of this association will be held in Philadelphia, commencing Wednesday, September 12, at 10 a.m., and continuing three days, at the time of the fifty-fourth exhibition of the Pennsylvania Horticultural Society, Horticultural Hall, Broad, near Locust. All horticultural and kindred associations in the United States and British provinces are invited to send delegates, and all persons interested in the cultivation of fruits are

flues on account of the constant attention needed to regulate the steam to the height necessary to keep the heat wanted. At that time there were doubtless few places where enough glass existed to admit of steam heat being economical; but the case may be different now when glass erections for garden purposes frequently exist that may be reckoned by acres, as well in private places as with those who grow for market, and it seems strange that steam is not tried in some or other of these large establishments. Where enough in this way has to be done to make it worth while keeping a man continually in charge of the apparatus there can be little doubt that so far as the cost of fuel goes steam would be cheaper than hot water; but whether the saving effected under this head would leave an appreciable gain when the extra labour in attention was taken into account, coupled with the extra cost in the fitting of steam pipes and a boiler capable of generating steam,

would have to be proved. Beyond this other matters would have to be kept in view, such as the continuity through the summer season of enough houses that required more or less heat to make it worth while keeping up the steam, which, needless to say, would, in this country in most establishments, be indispensable, for it is only for a very few weeks, if at all, that fire in large places can be done wholly without—very different from the conditions existing in the neighbourhood of New York. These matters which have an important bearing on the subject will be seen by those who are acquainted with the heating of garden structures. Every hot-water apparatus that has any pretensions to completeness is provided with valves so as to be capable of having the heat in each house regulated, just as would happen if steam was used.—T. B.

— I am pleased to see attention directed to steam heating. Some years ago, when on the Continent, I took charge of a large establishment where the arrangements for heating by steam were of a very complete description, and I doubt whether steam heating has ever been carried out on so large a scale in any other European garden. When we think of the vast areas of glass, such as, for instance, at Mr. Ladds, at Bexley Heath, Messrs. Veitch, Chelsea, Messrs. Low, Clapton, and other places, one can scarcely help believing that in such cases steam would probably be the easiest as well as the most satisfactory means of warming them. The heating apparatus in the establishment on the Continent to which I have just alluded warmed two large iron structures, each some 50 feet high, connected by a corridor which ran the whole length of the mansion. These houses were laid out in a natural style, the one nearest the boiler being planted with Palms and Musas, Ferns, Ficuses, and other tropical plants, and I may remark, parenthetically, that it was in this house that Musa Ensete first ripened good seeds in Europe; the leaves measured 30 feet in length, and the stem 2 yards in circumference. The other was a cool house, containing Camellias principally, also planted out, some of them 12 feet or more in height. The paths in all cases were composed of open ironwork, and the pipes being underneath it, none of them were sufficiently visible to offend the eye. If I remember rightly, they were inch pipes made of copper, and about a dozen of them together, the steam being let into them by means of a large pipe from the boiler, or rather boilers, as there were two of them fixed side by side. Few of the readers of THE GARDEN need be told that steam must first be "got up" before it can be employed. As a fact, there is a great difference between heating by steam and by hot water. By the latter method the water begins to circulate as soon as it reaches the boiling point, but with steam power a longer period must elapse before the temperature of the house can be raised, as a sufficient body of steam must be formed to enable it to force its way through the pipes when let into them, cleansing them of the condensed steam which they may contain. Nothing is lost, however, by this more tardy circulation, as when steam is got up to the right pressure the pipes are heated from one end to the other almost instantaneously. It used to take us about four hours to

GET UP STEAM when everything was cold; in an ordinary way one hour would suffice, and after the pipes were cleansed (I do not know the proper technical term), the furthermost ones were hot in ten minutes from letting in the steam. When I became familiarised with the details of management, I found this lapse of time useful. It allowed me to regulate the temperature with greater certainty and ease, and I was enabled to keep the cool house more at rest than I could otherwise have done. It was in this way I managed when the weather was uncertain; instead of heating the pipes early in the evening to make sure, as is often done, whereby cool houses are frequently over-heated and the inmates unduly excited, I just got up steam in the afternoon, kept the valve close, and let the fire out again. Here I had a reserve of force when I needed it; and if I found late in the evening that frost was setting in, I put

on the steam before retiring for the night, and all was safe. Then, again, if I found that either house was too warm, I had merely to close the valve for a time, or for the night, or give it a half or quarter turn, in this manner regulating the heating power with very great nicety. With steam one seems to feel a sense of power which he does not experience in the case of hot water. Properly managed, there is the ability to increase the heat very considerably at a moment's notice or shut it off altogether. It is true that by the aid of valves one may turn on or shut off hot water at pleasure, but the flow from the boiler itself cannot be stopped; the water must continue to circulate, if only in a limited area; whereas with steam the whole of the houses can be shut off and the steam bottled up, as one might say, for future use. It is handy to be able to do this when after a cold night in early spring, or indeed anywhere during the spring months, the sun suddenly shines and there is every prospect of a fine day. And often have I been obliged to rake out the fire in the morning when the sun has come out in a sudden burst, so as to guard against over-heating by a too sudden rise of temperature, but with steam power by closing the valve the pipes are quickly cooled down, whilst the confined steam keeps the water and boilers warm through the day, so that but little fire is required to get up the requisite power later on.

THE PRIMARY COST is very much against steam heating, as boilers and their fittings are more expensive than those required for hot water, and the best fuel is necessary. Coke will not do, and although when I got good English or Charleroi coal I never had any difficulty in getting the heat I needed, it was far different when I had only cheap Belgian material. I do not know whether steam heating is now much in favour with the Parisian market growers. At one time it was so, and I remember being much interested with what I saw in M. Savoie's establishment, the whole of the houses and frames there being heated by steam, one boiler, and that apparently by no means a large one, sufficing for the entire establishment.—JOHN CORNHILL, *Byfleet*.

TREES AND SHRUBS.

TREE PLANTING IN IRELAND.

A MEETING of the Statistical and Local Inquiry Society for Ireland was held in the Leinster Hall, Dublin, the other evening. Sir John Lentaigne presided. Mr. Fletcher Moore read a paper on the "Reafforesting of Ireland—its Advantages and Disadvantages," of which the following is an abstract: Reafforesting, for practical purposes, he said, means the planting of those waste spaces of inferior land which are unsuited for tillage, and yet are fit to grow trees. It is probable, however, that in selecting these places one would receive many different suggestions. The artist would likely choose some rocky eminence, and say: Plant there, to give effect to the landscape. The timber merchant would say: Timber will not grow there; you must plant here in this sheltered corner near the road, or the railway, or the sea, whence trees can be easily removed when ready. Whilst the agriculturist would certainly say: No, but plant that barren ground in narrow strips, and so I will have the intervening ground either for tilling or for grazing, and I will have the surrounding plantation to give a shelter to my cattle or crops. And in this latter view, in my opinion, lies the true principle of planting, as to how and where it should be placed. By adopting the first view, the hardest and poorest quality of timber trees only could be grown, and even then they would be too far from the road to be profitably removed when they attained any size; but by taking the third course and planting for shelter as well as profit, a part of the initial expense might well be placed against the shelter it would bring, and the practically new climate it would make through that shelter. Nor is this improvement of local climate caused by shelter imaginary; it is real. I know well a mountain farm in Wicklow on which, by judicious planting in belts, the place has be-

come quite different in its local climate from the surrounding mountains, and the plantations are highly valuable for their shelter, though practically valueless as timber, owing to their distance from a demand. Having gone thus far as to the advantages, there still remain two great questions which may be called the disadvantages: Firstly, will planting pay? and secondly, how can it be carried out? Now, as to expense: before a tree is planted it will be absolutely necessary to fence in the intended site. It is, of course, impossible to put down any fixed sum as the cost per acre of fencing a plantation when we do not know either its size or its shape; but from my experience I would say that a moderate-sized plantation, under the most favourable conditions, could not be set down for fencing at less than £8 per statute acre, small and narrow plantations costing very much more. As to the cost of planting, we will require at least 4000 trees per statute acre, planting them a little over 3 feet apart. And here I would urge the greatest care in selection of the young trees, not only to get them strong and flourishing, but also to have them of a quality and description to suit the soil and the purpose for which they may be intended. If shelter be required, Scotch Fir or Black Austrian are, perhaps, the best. If for ornament, Austrian, Silver, and Spruce. (I omit the more expensive kinds, as being more suitable for demesnes than for waste lands.) If for profit, then Larch, and that only; for it is now the only timber, except, perhaps, Oak for Oak bark, that can be called valuable in its earlier stages; but we must bear in mind all the time that if the intention be to replant where trees have grown recently, then the class of tree should be changed from the former crop, or great disappointment may ensue. Thus, Larch after Larch would not succeed well. In Scotland they plant very small trees, and even, I believe, seeds; but this will not be found advisable in this country, as the rank vegetation would most probably choke them. The cost of these trees will be found at present to be about 25s. per thousand for good Larch; for Scotch and Spruce, 21s. to 23s.; and for Austrian and Silver, £2 to £3. In some places planting is done in a very cheap manner with a planting pickaxe, which makes a slanting hole in the ground, into which the roots of the young trees are thrust sideways, and with little ceremony. The more laborious and expensive way of digging a separate hole for each tree is, however, far preferable and cheaper in the end; for I have seen the tree which had been accommodated with the hole beating out its axe-planted neighbour, which always seemed to have been growing its roots off to one side only, and to have kept a curve in its base from its original bad treatment. The digging of these holes and planting the trees may be set down at 18s. per thousand at least. So we have for trees, say £4 10s.; for planting, say £3 10s.; and fencing, say £8; or say £16 per acre statute for initial expenses. We have, then, to pay a man for the first two years to tighten in wind-shaken trees, and perhaps to replace some dead ones, and then for twelve years there are poor rates, county cess, and income tax to be paid, though there is no income to pay them out of; and, besides all these, we must debit the planting with the rent; for, no matter how poor the land is, if it be fit to grow trees it will possess some value for grazing purposes. About the twelfth year some of the young poles may be cut out for sale; these, when of Larch, were some years since bought for the English Hop fields at from 1s. 6d. to 2s. 6d. each, but this demand has apparently ceased, and there is now only the small local demand for light Larch poles at a very low price, whilst Spruce and Scotch of that age are quite unsaleable. Finally, we may sum up the question whether we shall reafforest or not by saying: If you want shelter, then plant for shelter. If you want to add to the beauty of the scenery, or to give employment to labourers, then plant for that. But as to planting trees as a speculation, and waiting for twenty-five years to get some profit, one feels inclined to say, "Don't."

Mr. Jonathan Pim said he was quite confident that the advantages that would be afforded by re-

afforesting were not exaggerated. The planting of trees would, he believed, have a most important effect on the general welfare of the country. The climate would be improved. It would have an effect on the floods of rivers if the high lands from which they flowed were planted. Trees husbanded the water that fell from the hills. There was a great deal of land in Ireland which was of very little value for grazing, and was of no value whatever for tillage, and such land would, he believed, be well suited for planting. He did not, however, think that planting would be a pecuniary success unless it was done in large spaces. The question was well worthy of the attention of the Government. In some years hence timber would be much more valuable than at present, owing to the reckless and extravagant way in which it was used.

Mr. Thomas Connolly said that the man who planted a forest on the hill side was a benefactor to his country, for he did a work which added to the wealth and ornamentation of the country. He mentioned that when he was a boy the late Earl of Dungarvan planted a quantity of timber, which was now worth about £50,000. He spoke of his knowledge of forest timber in America, and said it was wonderful where trees took hold—on sides of hills and mountains, where, in many instances, there was but little soil.

Mr. William F. Black said that years since he planted from 150 acres to 200 acres with Larch and other timber, and he could speak of the practical result, that he had now a large number of trees, for which he got 10s. a ton.

The chairman spoke in favour of Dr. Lyons' proposal, and, after some observations from Mr. Moore, the meeting adjourned.

Pruning overgrown Rhododendrons.

—It is not possible to prune the best hybrid Rhododendrons back to the old hard wood without making some sacrifice, especially if the pruning must be done all at once. In any case, the loss of one season's flowering is unavoidable. If I had to deal with plants that had got overgrown, I should leave the pruning until they had gone out of flower; I should then cut back some of the branches that required it—that is, I should thin them out, cutting back a portion of them this year, and the remainder next. The branches left to be operated upon next year would flower in the ordinary way, and the loss of blossoms would not be so serious as if all the pruning was done at one time. A good deal must, however, depend upon how much pruning is required; if there are many branches to be cut off, and if the wood is old and hard through age, it will be better to do all the pruning at once, and the best time to do it is early in February, as early pruning will give a longer season of growth for the young shoots. If there are a good few rather large branches to be shortened back, they will break into growth more regularly if cut away altogether than if the time is extended over two seasons, because the branches left the first year would in all probability use up all the strength from the roots, and the cut-back branches would probably die. But in dealing with the young growth of Rhododendrons the case is different; in that stage they do not object to a little pruning, although they are better without it. A young shoot shortened back, either before or after flowering, will break into growth the same year, and if the pruning is done in February, the growth so made may flower the following season; but it must not be expected to do so if the pruning does not take place till after the flowering season is over.—J. C. C.

Sikkim Rhododendrons (*E. Scudall*).—The specimen you send is *R. Nuttallianum*, one of the finest of all, and distinct from any other Himalayan species.

Osler growing.—I would recommend "R. G., Month" (p. 200) to procure a small pamphlet on the Osier by Mr. W. Sealing; published by Simpkin Marshall. Mr. Sealing gives the average cost of planting Osiers per acre as under: Digging and preparing, £3; 35,000 cuttings at 10s. per 1000, £17 10s.; planting at 1s. per thousand, £1 15s. Total, £27 5s. He uses sets 10 inches long, and pushes them quite into the ground.—JOHN MATTHEW, Addington.

Philesia buxifolia proved hardy at Chester, and stood in a bog bed for many years, where it flowered and appeared to be quite at home, till removed in making alterations, when I lost sight of it. It is stated (p. 380) that *Lapageria rosea* was introduced into this country by Messrs. Veitch. I am inclined to question this. London gives 1847 as the date of its introduction. I believe the first plants came to the Walton Nursery, Liverpool, where for some years in succession roots of it were received among imported seeds of *Araucaria imbricata*, and it was some time before they could be made out, as they laid two and three years in a dormant state. I well remember purchasing a plant of *Araucaria* in 1836, and a plant of *Tropeolum Jarratti*, which at that time was only obtainable at the Walton Nursery. I was informed at the time I bought the plant that it was then flowering at Eaton Hall, Cheshire, the first plant having been sent to the late Mr. Collinson, then gardener there.—T. SHORTT.

ORCHIDS.

Cypripedium ciliolare superbum.—

From Messrs. Sander & Co., St. Albans, we have received flowers of this handsome variety, which differs from the ordinary form of *C. ciliolare* in having larger flowers with broader segments, but most of all in the colour, which is much richer than usual. The broad dorsal sepal is white, lined with bronzy green and flushed with purple. The lateral sepals, too, are broad, much suffused with purple, and copiously studded with black spots. The pouch of the labellum is a dull vinous purple. Altogether it is a handsome flower, and, being but recently introduced, possesses the additional charm of novelty. *C. ciliolare* is a near ally of the older and better-known *C. Argus*, but there is a well-marked difference between both as regards the form and colour of the several parts of the flower and the foliage, which is more conspicuously tessellated in *C. Argus* than in the newer species.

Hardy Orchids.—Enclosed are the first blossoms from my Orchid bed. The early purple Orchis (*O. mascula*) is unusually strong and floriferous this season, and when seen in patches, as grown here, with from a dozen to twenty flowers in a group the effect is charming. This Orchid is wonderfully improved by cultivation, and when thoroughly established on good garden soil becomes stronger and more handsome each year. Other Orchids in flower at present are *O. pallens*, with lovely sulphur-yellow flowers and large elliptical leaves; *Ophrys exaltata*, a rare Italian species, having large reddish brown and yellow flowers; and *Orchis longicornu*, an attractive and very desirable species. The latter is a native of Barbary, but perfectly hardy here, having stood unharmed through the winter with the simple protection of a flower-pot during frosty weather. The flowers are very conspicuous, arranged in a rather dense mass near the top of the stem, and with a long flat spur or horn from which the name is derived.—A. D. WEBSTER, *Llandegai, Bangor*. [Some excellent spikes of hardy Orchises accompanied this note, showing clearly that Mr. Webster knows well how to cultivate them.]

Odontoglossum vexillarium.—Of this lovely Orchid, the undisputed queen of the genus, Mr. Bull has at the present time a marvellous display in his nursery at Chelsea, the loveliness of which without seeing it no one could form an idea. The plants, all fine specimens carrying crowds of spikes, may be counted by the score, or indeed by the hundred, and, as may be imagined, they form, when in full bloom, as they are now, a rare floral display such as probably could not be seen elsewhere. Each plant is a picture in itself, being in perfect health, with spotless foliage, and carrying numerous long elegant spikes of flowers which in some varieties are a deep rich rose tint; others are almost white, and every intermediate shade may be found, while some even have two colours, white and rose. All are beautiful, but the deepest tinted forms have most admirers. There is a great diversity as regards the size of the flowers

and the number borne on each spike, but this character of course varies with the size and strength of the plant. The cultivation of this Orchid is certainly understood at Mr. Bull's, for it could not be possible to have the plants in a more perfect state. The collection of this Orchid is alone worth a long journey to see apart from the other Orchids which here form so important a feature. The housefuls of *Cattleyas* and *Dendrobies* are very fine just now, particularly the cool Orchids, such as *Odontoglossum crispum* and *Pescatorei*, *Masdevallias*, and others, which are now at their brightest. Two *Oncidiums* are worthy of special notice. These are *O. concolor* and *O. Marshallianum*, both of which are numerous represented here, as they hang under the roof throwing out their long elegant spikes they look like swarms of golden butterflies. Both are indeed lovely plants, and the most select collection of Orchids is incomplete without them.

Epidendrum bicornutum.—Among the numbers of Orchids in bloom in the Kew collection this is one of the most beautiful, and by far the most noteworthy. Almost every season we have to note with what success this reputedly difficult Orchid is grown at Kew, and this year forms no exception. At present there are several fine plants of it in flower bearing several erect spikes from the tops of the bulbs, each of which carries from three to ten lovely white blossoms, which remain a long time in perfection. The flowers are nearly 2 inches across, having broad, overlapping segments of thick, wax-like texture, and pure white, exquisitely spotted and freckled with purple. It is without exception one of the loveliest Orchids in cultivation, but the fact that many do not succeed with it no doubt deters many from acquiring it; hence it is not a common plant, though there have been large importations sold of it. Being a native of Trinidad, it requires a warm, moist, and close atmosphere, particularly while developing its growths; but it is not often that it makes so large growths in this country as it does abroad. It is, indeed, a plant that well repays any special care and attention. At Kew it is grown in the usual Orchid compost in pots, but we have seen it succeed well attached to suspended blocks of wood.

Epidendrum rhizophorum.—Herewith I send some flowers of this Orchid, also a photograph of the plant from which they were cut. I have often wondered why this plant is not more frequently grown than it is, seeing it is so extremely floriferous, and that the blossoms are so bright in colour. When its portrait was taken (last year) the plant had eighty-six racemes on it; it measured 3 feet by 3 feet, and was in flower quite nine months. At the present time it has about the same number of racemes; it has been in flower about two months, and promises to continue so throughout the summer. Not only is it a grand plant for show purposes, but for cutting; the individual flowers can be turned to good account for filling small glasses and for button-hole bouquets.—R. GILL, *Tremough, Penryn, Cornwall*. [The specimens sent are exceptionally fine, as many as thirty flowers being in one cluster. The colour is a brilliant orange-scarlet, brighter than that of *Epidendrum vitellinum*, the yellow colour on the labellum tending to intensify the red. It is a very showy Orchid, and, as Mr. Gill remarks, ought to be more generally grown than it is. The photograph represents a truly wonderful plant, which when seen in full beauty must present a rare floral sight. Mr. Gill evidently knows how this Orchid should be managed.]

The Orchid houses at the Royal Exotic Nursery, Chelsea, are just now in their height of floral gaiety, and the hosts of Orchids of all kinds form a beautiful exhibition in themselves. The *Cattleya* house contains crowds of *C. Mendellii* in great variety and numerous other species, besides such lovely things as the forms of *Laelia purpurata* and *elegans*. The *Dendrobium* house, though not so gay with bloom as it was a few weeks ago, still contains sufficient bloom to make it extremely attractive, and amongst the numerous kinds we made special note of the lovely *D. primulinum giganteum*, one of the finest plants

in the whole genus. The *Odontoglossum* houses were never more attractive than they are now, containing, as they do, a perfect thicket of flower-spikes of such as *O. crispum*, *cirrhosum*, *triumphans*, *Pescatorei*, *gloriosum*, *Halli*, *luteo-purpureum*, besides numerous rarer species, such as the true *O. O. navium majus*, which is indeed a lovely plant, having short crowded spikes of flowers similar to those of *O. cirrhosum*, but more finely spotted. The *Vandas*, too, are a fine feature, particularly *V. tricolor*, which is represented by such as *Dalkeith*, *Paterson's*, and other splendid varieties. The housefuls of *Phalaenopsis* and *Lycaste Skinneri* are still bright with bloom, and so is the *Cypripedium* collection, which contains a large number of the handsome hybrids raised at this nursery. The following hybrids may be seen in flower: *C. superciliale*, *porphyreum*, *calurum*, *selligerum*, and the major variety, *vernixium*, *Harrisonianum*, *calanthum*, *Domini*, and *Sedeni*. Besides these, there are several of the finest species in bloom, such as *C. Stonei*, *Veitchi*, *Lowei*, *Spicerianum*, *Argus*, and *Warneri*.

Masdevallia Shuttleworthi.—In order to fully realise the beauty of this little gem among Orchids, one needs to see it in such numbers as we saw it the other day at Messrs. Shuttleworth & Carder's nursery, Park Road, Clapham, where in one of the houses is a row of about a score plants, on which we counted no fewer than sixty blossoms and buds, a proof of the extreme floriferous tendency of this *Masdevallia*. This line of plants seen from one end, every one bristling with spikes, was a pretty sight, as the flowers are not only attractive in colour, but quaint in form. Mr. Shuttleworth, who first discovered this little Orchid, evidently knows exactly its requirements, for we have rarely seen the plants in a healthier condition. He grows it in shallow pans suspended close under the roof of a house containing *Odontoglossum crispum*. He gives abundance of water while the plant is in active growth and developing leaves and flowers, and it is almost a perpetual flowerer. The great drawbacks to the plant are the fogs in winter and early spring, and it seems to be very susceptible to injury by them. Among other *Masdevallias* we noted here in bloom were some exceptionally fine forms of *M. Harryana* and *Lindeni*, and particularly of *M. Veitchi*, and one plant seems to be identical with that called *grandiflora* or major, as the flowers are considerably larger than usual and the colours brighter. A rarity is *M. Roezli*, also in bloom. It is one of the *Chimæroid* group, having large triangular flowers, almost black, and a white slipper-like labellum. The housefuls of *Odontoglossum crispum* and other species here contain numerous uncommon varieties, such as *O. mulus*, *Wilkeanum*, *prionopetalum*, *crispum roseum*, and a form similar to both *O. Ruckerianum* and *Andersonianum*, but seemingly between the two. The flowers have the flushings of purple in the former and the spottings of the latter, but the spikes are shorter and more crowded. It is an extremely handsome variety.

QUESTIONS.

The Gooseberry trees in my garden have had most of their fruit buds picked out this spring. I have heard that twining worsted amongst the branches will keep the birds off. Can any of your readers say if this is effectual? and at what time it should be done?—T. H.

Intermediate house temperature and plants.—I should be obliged for a few hints on the management of an intermediate house, especially with regard to the temperature to be maintained in summer and winter. A brief list of the names of the most suitable and choice flowering plants, not Orchids, would also be valued.—IXION.

Spent Hops as manure.—We are badly off in India for manure. There are no artificial manures available, and import is too expensive to be thought of; therefore, it is most desirable that we should avail ourselves of any and every substance at hand. There is a brewery near me with a very large quantity of spent Hops. What I wish to know is whether their use as a manure is detrimental, or the reverse; and also in what state, whether decomposed or fresh, and in what proportion, as compared with ordinary farmyard manure, it is proper to use the same.—JOHN W. BARIN, *Vergemont, Naince Tal, India.*

SINGLE-HANDED LAWN MOWERS.

AT the International Exhibition held at the Botanic Gardens, Manchester, in 1881, an impartial and exhaustive trial took place with several good machines on dry and wet, also on short and long, Grass. After several very severe trials on different days, the real contest lay between the machines named below, several others having been eliminated after the first trial. The points of merit from which they were judged were as follows:—

	Invincible. 14-inch cutter.	Anglo-American 14-inch cutter.	Excelsior. 14-inch cutter.	President. 14-inch cutter.
1st.—Simplicity and strength in construction.	3	2	2	2
2nd.—Lightness of draught.	3	4	2	1
3rd.—Smoothness of cut.	4	3	2	1
4th.—Adaptability for cutting either long or short Grass.	3	4	1	2
5th.—Suitability for cutting close to flower beds with the least injury to plants.	4	2	3	3
6th.—Comparative noiselessness in working.	3	3	2	2
7th.—Cost (equal) —£5 10s. each.	0	0	0	0
No. of points:—	20	18	12	11

I do not think that these public trials should be taken altogether as the most satisfactory tests of the real value of a machine, as, after all, the efficiency of a machine, irrespective of the principle on which it is made, depends to a great extent upon the quality of those working parts where the greatest friction occurs, and that can only be proved by frequent use. These contests are, however, of some value, as they afford convenient means for comparison, where everyone has an opportunity of judging for himself before purchasing—means which could not easily be otherwise obtained.

T. CHALLIS.

Fallacies about lawn mowers.—Allow me to offer "An Old Lawn Mower" (p. 370) a challenge. I am not agent for any maker of machines; I do not sell machines, and what I propose shall be done at my own expense. I will take to "An Old Lawn Mower's" place one 14-inch and one 16-inch Excelsior lawn mower, and will myself cut any native Grass on his lawn or pleasure grounds, or even meadow, which does not exceed 5 inches in height above the edge of the wiper plate, sole plate, or knife plate, or whatever it is called, or say 6 inches upright from the soil, if the soil is firm and not like a bog; and if "An Old Lawn Mower" prefers it he can use the machine himself; the only penalty or expense that he will incur is that he shall write an accurate report of the trial to THE GARDEN, whether it be a failure or success. I will also undertake that the machine shall, on any ordinary lawn, cut as close, as well, and far easier than any other standard English machine of the old form which has more than six knives or cutters on the wiper, and that any ordinary lad of fifteen years of age shall use a 14-inch machine for any reasonable time without undue fatigue more than that caused by the exertion of fast walking. Will "An Old Lawn Mower" accept the challenge? If so, let him signify his acceptance to me at the address as under. The only reservation I make is that, as my time is limited I cannot come to him if he resides more than 250 miles from London, or so far from a main line station that I cannot catch a train to London the same night as the trial.—W. J. MAY, *Walton-on-Thames.*

THAT terrible, old, and half rotten shed by which one enters the Royal Horticultural Society's garden at South Kensington is still standing, but its effect on gardening cannot be wholesome, looking at it in what way we may.

NOTES OF THE WEEK.

APPOINTMENTS FOR THE WEEK.

May 8.—Royal Horticultural Society.—Meeting of Fruit and Floral Committee at South Kensington at 11, and Spring Show; and Meeting at Linnean Society's Rooms at 8 p.m.

9.—Bath Spring Show.

11.—Manchester Great Whitsun Show opens.

RECREATION GROUND FOR NEWCASTLE-ON-TYNE.—Sir William Armstrong has extended his gift of his Jesmond Park estate to the public by the addition of a recreation ground of fourteen acres, including the classic ruins of St. Jesu Mount, from which Jesmond, the most picturesque suburb of Newcastle, is named.

AN EXHIBITION OF ROSES in pots is now on view and will remain so until the 10th inst. in the Royal Botanic Society's garden, Regent's Park, where there are some hundreds of plants all admirably grown and flowered, representing a good selection as regards varieties. The plants are from Messrs. W. Paul & Sons' nurseries, Waltham Cross.

FLOWERS OF IRISES.—Dr. Foster writes: "I shall be deeply indebted to anyone who can send me blooms of *I. susiana* or *I. iberica* to illustrate my paper on Tuesday next. I have some of my own, and friends have kindly promised me others, but I am anxious to have more, especially to show varieties. Any blooms addressed to me, care of Dr. Murie, Linnean Society, Burlington House, W., so as to reach there not later than Tuesday afternoon, May 8, will be duly taken care of and acknowledged."

PUBLIC PARK AT DOVER.—The public park, which has been laid out at a cost of several thousand pounds, was this week formally presented to the town. The ceremony took place at the grounds, where the key was handed over to the Mayor. The park occupies an extensive site on some twenty acres or more in one of the most prominent and beautiful situations in the town. The land is Government property, but has been granted the lessees at a nominal rent, the project being warmly supported by Lord Granville. The park will be publicly opened by the Duke and Duchess of Connaught in July.

COMBINATION FERN POT AND FLOWER BOWL.—We send a specimen of this for opinion. When fitted up with a Fern, which is planted in the Minton porous lining and placed in the centre cavity, and cut flowers well arranged round the bowl, the effect as a low table decoration is very good. We make these new pieces in various colours and sizes, and they can be obtained from any respectable dealer.—STEVENS & WILLIAMS, *Brierley Hill, Staffordshire.* [A good idea, but not well carried out. Manufacturers do not seem to be aware of the value of simple form, and of avoiding the use of coloured glass. Common glass is what we want—good in form. The basin, which is set on feet, seems too high from the table for the small flowers that could be put in the outer rim. Try a simple model with the centre and basin both resting on the table, thus avoiding the use of the elaborate legs. A good size larger is also desirable.—ED.]

GRAVEYARD GARDENS.—The defenders of public property against the encroachments of private bill legislation, who have on the whole been so successful of late, met with a sad check in the House of Commons the other evening. Few worse precedents could possibly have been set than that which is afforded by the decision of the House to allow the London and North-Western Railway Company to take one half of a disused cemetery in the centre of St. Pancras—not more than one-tenth of which the railway actually wants, and every inch of which the neighbourhood wants—in order to provide £15,000 for "parochial, ecclesiastical, and other purposes" of St. James's, Piccadilly. It is true that the majority against Mr. Holland's motion was a very small one—only 11 in a House of 350—and that there is still a hope that the House of Lords will expunge the ob-

noxious clause of the Bill. But the vote will remain as fresh evidence of the constant danger to which the public are exposed from these piecemeal encroachments, and a fresh warning to incessant vigilance. The simple fact in this case is that an acre and a half of open ground is to be taken away from us for ever, and that unnecessarily; whereas a garden of three acres would have been a boon to the public, and especially so in the densely inhabited quarter in which it is situated. Every little space where the wind can freely circulate, and air charged with human breath and all the vapours emanating from human habitations can, in however small a degree, be purified by contact with leaves and grass, is of vital importance to the health of London; therefore the loss of the space just referred to must be looked upon as a loss of more importance than at first sight it might appear to be.

ROYAL HORTICULTURAL SOCIETY.—The first evening meeting of this society for 1883 will be held, by permission of the Linnean Society, in their rooms, Burlington House, Piccadilly, on Tuesday, May 8, at 8 p.m., when the chair will be taken by the Right Hon. Lord Aberdeen. Communications from Dr. M. Foster, F.R.S., on "Iris susiana and its allies, their nature and culture;" Dr. Hogg, on "Australian Apples;" Mr. E. G. Loder, on "Hardy Cacti, their habitats and culture;" Herr Max Leichtlin, on "Some novelties in the garden at Baden-Baden;" and Mr. W. Goldring, on "Cypripediums," will be read. Two-guinea Fellows may personally introduce one and four-guinea Fellows two visitors as guests.

BARR'S BLACKING BOTTLES AT THE BOTANIC.

TO THE EDITOR OF THE GARDEN.

SIR,—Give me a little space to air a grievance. I entered the Royal Botanic Society's corridor on the 25th inst., at the spring flower show held on that day, and the first thing that met my eye on the right hand was a number of beautiful Narcissi, with varieties of the order, stuck together in separate receptacles without any attempt at classification or arrangement, as if they were for sale at Covent Garden Market, the exhibitors being Barr and Son. Will it be believed? Oh, horror! these receptacles were several dozens of blacking bottles—yes, blacking bottles, pure and simple. *Credat Judæis!* I looked a second time, and again, to make sure my eyes did not deceive me. There was not a bit of Moss, nor Sphagnum, nor anything else that would have hidden the nakedness of the unsightly articles of earthenware. How easy it would have been to have plunged these bottles into a bed of either one or the other, and so have avoided offending the eyes of the visitors to the garden. This is not the first time Messrs. Barr's collection has been exhibited in somewhat the same style, but I trust it may be the last.

Charles Baltet. Extrait du Tome 127 Mémoires de la Société Nationale d'Agriculture de France. Paris: G. Masson, Editeur, 120, Boulevard Saint-Germain.

SOCIETIES.

EXHIBITION OF HORTICULTURAL BUILDINGS.

AN exhibition of horticultural buildings, heating apparatuses, and other garden appliances has been opened at the Agricultural Hall, and will remain open till May 16. The show is not a large one, but a few well-known firms are among the exhibitors. Messrs. Messenger and Co., of Loughborough, exhibit a strong, well-made conservatory heated with one of their Loughborough boilers, also garden frames or ground vineries, the sides of which are of thick clouded glass instead of wood, a great advantage during spring and summer. Wood sides could be substituted in a few minutes if it were desired to place the frame on a hot bed. Mr. B. W. Warhurst, Highgate Road, exhibits heating apparatuses from oil and gas stoves, capable only of keeping the frost out of a small greenhouse, to the great Ben's boiler, capable of heating over 1000 feet of piping. The same exhibitor also exhibits a useful contrivance named the greenhouse cabinet, which consists of a polished cupboard, in which are placed ten tools, useful in the greenhouse and garden, including syringes, &c. Messrs. Dodds and Robb, of the City Road, exhibit a well-made, portable span-roofed greenhouse for £20, and other exhibitors have smaller houses as low as £6. Messrs. Deards, of Harlow, show a lofty house glazed without putty, and furnished with zinc bars, so that paint is not required. Messrs. Wrinch & Sons, of Ipswich, also show a span-roofed house and various other garden appliances, such as mowing machines, lawn tennis requisites, &c. Messrs. Hooper & Co., of Covent Garden, have a summer house, garden seats, stools, and fancy flower-pots and vases filled with dried grasses. Messrs. Thomas & Co., of Edgware Road, show wire arches, baskets, Peaguards, &c.; and rustic summer houses, seats, &c., were shown by Mr. Henry Lovegrove, Slough, Mr. Trotman and Mr. Inman, of Manchester. Useful implements, such as Potato-parers, Cucumber-slicers, &c., may also be found in quantity, whilst anyone interested in house furnishing may probably spend an hour in inspecting the furniture trades' show, now also being held in the hall.

At the Vienna spring show a small collection of hardy plants from Herr Max Leichtlin's garden at Baden-Baden was very interesting. Amongst others I noticed the Bayonet plant of Australia, a singular production, with sharply pointed sword-like leaves; the double-flowered variety of *Primula acaulis*, *P. floribunda*, *P. rosea grandiflora*, *Aubrietia Leichtlinii* and *A. Hendersonii*, *Trillium discolor*, with beautiful spotted leaves, and some cut flowers of *Tecophylaea cyanocrocus*, the last very conspicuous. From the Imperial Gardens, Vienna, which are noted for Bromeliads, came a huge specimen of *Vriesia fenestralis*, *Æchmea Marie Regine*, *Androlepis Skinneri*, and *Æchmea Veitchii*. Amongst the collection of Orchids sent from Baron Rothschild's gardens were fine flowering specimens of *Houlletia Brocklehurstiana*, *Dendrobium macrophyllum*, *Odontoglossum Roezli majus*, *Cyrtopodium Andersoni*, and *Cypripedium superbiens* (Veitchii). In a group of market plants small flowering examples of *Kalmia glauca* and *Rhododendron suavisimum* were noteworthy.—LOUIS KROPATSCH, *Laxenburg*.

The Sadler family fund.—Will you allow me to call the attention of our hardy plant fraternity to the fund now being collected for the family of the late Mr. Sadler? The Edinburgh Botanic Garden rockwork and hardy plant ground was, as is well known, one of the early successes in alpine plant growing. This was a hobby of the late Mr. McNab, and well carried on by his successor, Mr. Sadler. Hardy plant growers have benefited by his work. Mr. Sadler died at the early age of forty-five, before he had time to make provision for his large family, who are left very poorly off. A relative, the scientific head of the Edinburgh Botanic Garden, called my attention to the fund. I have found friends disposed to

contribute, and now ask the favour of the large circulation of your columns to make the fact that a fund is being raised more generally known. Dr. William Craig, F.R.S.E., 7, Lothian Road, Edinburgh, is the receiver of subscriptions.—GEORGE F. WILSON.

Nursery sick fund.—The secretary sends us the details of a sick fund established amongst the numerous employes at the Cranston Nurseries, Hereford. Persons interested in such things may obtain a set of the rules on application to the secretary, Mr. J. T. Mayo. For many years past it has been the custom in these nurseries to make collections for some of the workpeople when ill, but the promoters of this fund consider it a better means of encouraging their workfellows to assist themselves should sickness overtake them.

Tar on pipes.—Having been three years ago in the same predicament as your correspondent (p. 342) from having greenhouse pipes coated with tar varnish, I wish to inform him that two paintings with Carson's "Detergent" removed the tar after all other means had failed. It is needful to remove all the tar, as in one house where all the piping could not be reached to be entirely cleansed, the plants to this day show that they feel its unwholesome influence. Lampblack and oil should be used on the pipes when free from tar.—J. J. W. P.

OBITUARY.

The late George Rollisson.—We had hoped there was no truth in the rumour current last week of GEORGE ROLLISSON'S death, but the sad facts have now been published with details too complete. In common with all who knew him, we feel great regret that the life of one who had in all probability so many years before him, and was so full of intelligence and vigour, should have ended before he had attained the prime of life. The sad reverses of the family had no doubt preyed on his mind. After the break-up of the firm he faced his fate manfully, and, as we have reason to know, accepted his duties at Kelsey Manor with good heart and energy. He has more than once told us of the kindness and consideration with which he was treated there and how happy he was in his work. Among all the younger generation of the nursery trade round London some years ago there was not a more manly or promising young man or one more likely to do credit to his house and family. We repeat it is with real regret we have to speak of this last incident in a sad chapter. Of the rest it is not for us to judge.

Royal Botanic Society (C.).—You should apply to the secretary, from whom you will probably get what you want.

Laced Polyanthuses.—Flowers of an excellent strain of gold-laced Polyanthus reach us from Mr. B. S. Williams' nursery, Upper Holloway. The flowers are of fine symmetrical shape, the lacing well defined, and the centre bright and perfect.

Colouring hot-water pipes.—"Ixion" (p. 365) wishes to know of an effectual means of doing this. It cannot be better done than by giving the pipes two or three coats of stone-coloured paint. This answers perfectly, and has a better appearance than black, or perhaps any other colour.—P. G.

Lælia majalis.—We have now in flower here several plants of this beautiful Orchid. One, a very fine variety, measures 6½ inches across; the lip measures 2 inches in diameter.—HY. CLINKBERRY, *junr.*, *Forty Hill, Enfield*. [We should like to know what treatment our correspondent gives this Orchid.]

Names of plants.—C. M.—1, *Erica aristata* (two flowered specimen); 2, *E. suaveolens*. Sticky Heath should not be packed in cotton wool, nor should the flowers be crushed, or it is almost impossible to name them.—*Anon.*—1, *Dendrobium luteolum*; 2, apparently *D. crepidatum*, but too damaged to name correctly.—*M. S.*—*Doronicum canescens* (yellow); *Cochlearia danica*.—*J. Featy.*—1, *Adiantum Sanctæ-Catherinæ*; 2, *Selaginella Mertensii*; 3, apparently *S. stenophylla*; 4, *S. viticulosa*.—*A. M. Z.*—*Polytrichum commune*.—*N. A.*—*Chlorophyton orchidastrium*.—*J. Rogers.*—*Boronia eltiot* (pink); *Tabiana imbricata* (white).

No. 599. SATURDAY, MAY 12, 1883. Vol. XXIII.

"This is an Art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

FLORISTS AND THEIR FOIBLES. TO THE EDITOR OF THE GARDEN.

SIR,—I was much pained by reading in THE GARDEN (p. 410), under the above heading, an unprovoked attack on lovers of florist's flowers in general, and of Auriculas in particular. What have we done to provoke your correspondent "Peregrine's" contemptuous anger? Taking the lowest ground, we are a harmless fraternity, treading on no man's corns, riding our gentle hobby along the broad horticultural highway, thankful for the aptitude for so much pure and innocent enjoyment. But, stay; I am going on too fast. Doubtless your correspondent will refuse the epithet innocent to our pursuit. We must plead guilty to being not satisfied in all cases with "that beauty of Nature's flowers which is usually stamped on the face of them for bees and butterflies and man to see." We are not bees or butterflies, nor do we regard flowers from the same standpoint as they do. A bee or a butterfly is quite satisfied with a common Pansy, for instance. The florists, recognising latent capabilities of beauty, have patiently worked for and attained a high standard of perfection. Looking on the wildling and on the florist's Pansy, will "Peregrine" undertake to say that he is on the side of the butterflies and bees, which are well content with the former? If he will not, then he speaks claptrap; but if he will, we can only say he is pretty likely to be alone in his taste. Take another instance. "Ordinary mortals, bees, and butterflies," according to "Peregrine," are on one side, while the miserable florists are on the other. Is this so? I suppose that any "ordinary mortal" would admire a faultlessly double Rose, which is one of the florist's triumphs; but I equally suppose that any tee of his acquaintance would confidentially tell "Peregrine" that it was a monstrous mistake to convert into petals those delightfully floury anthers from which he drew such stores of pollen. This pretty simplicity is simply nonsense. The Author of our being has implanted in ordinary mortals a sense of the beautiful. It has yet to be proved whether the lower animals have any sense of beauty other than in connection with ordinary purposes. Butterflies and bees are attracted by the colours and scents of flowers, not for the gratification of an æsthetic instinct, but for the mere purpose of seeking food. Thus we may, I think, dismiss them as witnesses in "Peregrine's" favour and against the florists. The mark which florists have left in the world of gardening is one which "Peregrine" cannot ignore. Every man who takes up the culture of a plant with the intention of working up to some preconceived standard is to all intents and purposes a florist; aye, as much so as any Auricula enthusiast; they pursue the same end by the same means. I know not how the National Auricula Society can have provoked "Peregrine's" high displeasure; but the Society can, I feel sure, well afford to bear the remarks of one so unfair as to say that "its members number very nearly half-a-dozen individuals." After stating this fact (?), he is safe to prophesy the speedy extinction of such a weakly society. Your correspondent then goes on to tell us what the florist

of the future will be like. I presume he means to indicate that the future florist will be exclusively what is called a "plantsman," in contradistinction to what is ordinarily known as a florist; but, alas! for his knowledge of what he is writing about. Among those whom he selects for honourable mention as the very opposite to the despised Auricula lover is Mr. Brockbank, the owner of one of the largest collections of Auriculas, an exhibitor at London and Manchester, and, oh, horror! a successful raiser of new varieties of the florist's Polyanthus. Because Mr. Brockbank, like myself, is a lover of hardy plants, he is not in consequence likely to thank "Peregrine" for assuming that he is not a florist. Scarcely less happy is "Peregrine" in his mention of Messrs. Veitch and Cannell to mention but one plant respectively for each. Surely the men who are doing for Amaryllises and zonal Pelargoniums what they are doing are florists in the old-fashioned acceptance of the word, pursuing the same ends by the same means, namely, a fixed standard of excellence, and the selection of those individuals which help to attain that standard.

I know not whether "Peregrine" is a lover of plants. I have been such all my life; but as he is not a florist also, I shall conclude by saying that I forgive him all the harsh things he says of us in consideration of his unhappy lot as one to whom is denied the inexpressible delight of gazing with thankful soul on a frame of Auriculas, a bed of florist's Tulips, a stand of florist's Dahlias, a box of florist's Pansies, or a collection of Carnations and Picotees.

Cloghran, Co. Dublin. FREDERICK TYMONS.

CHRYSANTHEMUMS FOR CUT FLOWERS.

AS we require a good many cut flowers of Chrysanthemums, we have lately been preparing, as is our usual custom, to provide for a supply from the open air. I have long since learnt that, owing to the frequent occurrence of early November frosts, we cannot depend upon securing these autumn flowers without some means of protecting them. We have therefore given up altogether their cultivation in the open borders, and have taken to plant them against every available space on south walls. In this position we find them to do exceedingly well with a little protection when there are signs of frost sufficient to injure them. The plan of sheltering them which we adopt is a very simple one. We merely get a mat and nail it to the wall over the plant in the evening and take it away in the morning, and as frost of sufficient severity to injure Chrysanthemums seldom lasts more than a few days in November, it is really not a serious business to protect a few plants in the manner just described. We had an early taste of winter last year, but with the protection of a mat for a few nights our plants came safely through it and gave us a crop of flowers up to the middle of December. To secure the best results it is necessary to make a judicious selection of sorts. Amongst large-flowered kinds our selection includes Mrs. G. Rundle, G. Glenny, Mrs. Dixon, Prince of Wales, Mr. Gladstone, and Purple Prince. But the most satisfactory of any are the pompon varieties, nearly all of which may be used with every prospect of their doing well. Our selection includes President, Lilac Gem, White Trevenna, Jersey Beauty, Brilliant, Mrs. Hutt, Lilac and white Cedo Nulli, Mustapha, and Rose d'Amour. In order to grow Chrysanthemums successfully continuously in the same position, there must necessarily be an annual transplanting and an addition of some kind to the soil to prevent it from becoming exhausted. In our case we lift all the plants early in May and divide them, saving about one-third of the youngest part to plant again, and throwing the other away. Where the plants have been grown for several years on the same spot,

we remove all the old soil from the wall in the form of a trench 1 foot wide and 1 foot deep, and replace it with fresh material. In cases where they have only been planted one year in the same place we put a bit of rotten manure on the surface and mix it up with the soil. The plants are then put in close to the wall, and except that in very dry weather we give them an occasional soaking of water, they need no further attention till August, when they will have grown sufficiently to require some support to keep them close to the wall. This is effected by means of a couple of nails driven into the wall and a bit of tar-cord tied to each and stretched in front of the plant. This operation will require to be repeated as the growth extends up the wall, for it should be remembered the nearer they are to the wall the less effect frost has upon them. I may add that it is a good plan to thin out some of the stems early in summer where crowded, the result being larger flowers.

J. C. C.

PLANTS IN FLOWER.

NEVIUSIA ALABAMENSIS.—This new shrub is again in flower on a wall at Kew, and, as last year, the blossoms are tinted with green to such an extent that, judging by the plant in question, it certainly cannot be considered to be a desirable acquisition, and not likely to become popular. As regards beauty, it is surpassed by many others, such as some of the Spiræas, which in manner of growth it somewhat resembles.

AZALEA RHOMBEA.—In the arboretum at Kew this Azalea is now in flower, being by far the earliest to expand its blossoms, and therefore valuable in this respect. Their colour is a purplish mauve, nearly approaching that of *Rhodora canadensis*, which it succeeds; but, unlike the very small flowers of the *Rhodora*, those of this *Azalea* are moderately large. It appears to be but little known.

DISCARIA LONGISPINA.—This is a loose-growing shrub which requires the support and shelter of a wall, otherwise, like its allies the *Colletias*, it is often severely injured during winter. The slender branches are plentifully furnished with spines, and but sparingly with small, serrated leaves, but this latter is compensated for to a great extent by the bright green colour of the bark and spines. The flowers are white and bell-shaped, bearing some resemblance to those of the *Andromedas*. It is now in flower at Kew.

RHODODENDRON NUTTALLI.—A plant of this fine *Rhododendron* in the temperate house at Kew is now bearing half a dozen trusses of flowers in different stages of development, each truss or cluster consisting of from eight to ten large blossoms. The flowers when first expanded are of a greenish yellow colour, but gradually become whiter, till at last, except a flush here and there of pink and the cream-coloured throat, they are almost pure white. The large wax-like blooms of this species, which in colour contrast well with the many bright hued kinds, stamp it as one on no account to be omitted in a collection of Himalayan *Rhododendrons*.

RIBES SUBVESTITUM.—A very distinct species of *Ribes*, and one that forms a stout, free-growing shrub, the branches of which, especially in a young state, are thickly beset with spines. The flowers somewhat resemble small *Fuchsia* blooms, the sepals being chocolate tipped with green, and the petals white marked with pink at the base. Though not brightly coloured, they are borne in great profusion, and, combined with the peculiarly spiny branches, render it a desirable spring flowering shrub. It is a native of California, and is also known under the name of *Ribes Lobbi*. It is now in flower in the *Ribes* collection at Kew.

HARDY FLOWERS from Mr. G. Paul's nursery, at Broxbourne, comprise an exceptionally fine variety of *Saxifraga cordifolia* named *purpurea*. It has large dense clusters of flowers as deep a rose-purple as that of *S. purpurascens*, also sent from the same establishment. Associated with these

were likewise *Viola Munbyana*, a pretty purple species with flowers as large as those of a bedding *Viola*, and in bloom almost throughout the year. *Triteleia uniflora lilacina* with porcelain-blue blossoms, produced continuously from March throughout the summer; *Fritillaria pyrenaica*, with bell-shaped drooping flowers of a brownish red colour; *Geum miniatum*, a perpetual flowering variety with orange-red flowers; *Doronicum austriacum*, a handsome composite with large bright yellow flower-heads like a huge Daisy; and *Vesicaria utriculata*, an *Alyssum*-like crucifer with dense heads of yellow flowers. A beautiful gathering of Primroses and Polyanthes also accompanies these; the most noteworthy among the Primroses are *platypetala* fl.-pl., with large double plum-purple flowers; the old double crimson, still one of the finest doubles; and the handsome *Croussi* fl.-pl., with double rosette-like flowers of a rich carmine-crimson.

PIPTANTHUS NEPALENSIS.—Against a warm, sunny wall at Kew this strong, free-growing shrub is now in flower. It has trifoliate leaves and large, yellow, pea-shaped blossoms borne in erect and somewhat crowded spikes at the point of the branches. Being earlier in flowering than the *Laburnum*, it is very desirable, but except in the south of England it requires the shelter of a wall; in the open it is often cut down to the ground, even in the neighbourhood of London. It is easily propagated either by means of seeds or cuttings, and it flourishes in any ordinary soil, provided it is not too wet. When that is the case, the wood does not yet sufficiently ripened to survive the winter.

A GATHERING OF NARCISSI from Mr. George Paul's new hardy plant nursery, at Broxbourne, includes some very beautiful things, and also such rarities as *N. Graellsii*, a creamy yellow variety of *N. Bulbocodium*; *N. triandrus pulchellus*, with Cyclamen-shaped flowers of a sulphur yellow colour, borne in clusters of half a dozen on a stem; *triandrus albus*, similar to the last, but almost a pure white; *triandrus pallidus*, pale yellow; *N. Bulbocodium serotinus*, the latest flowered variety of all the Hoop Petticoats; and *N. Bulbocodium minor*, the smallest of the series, having a distinct wavy-edged corona. There is also a fine lot of beautiful hybrid kinds, such as *Leedsii superbus*, with white sepals and sulphur crown, and *Leedsii amabilis*, with a long, yellow-edged crown and white sepals; also *Horsfieldii*, *cernuus pulcher*, *moschatus*, and *cernuus*, four of the finest trumpet varieties. We are glad to find nurserymen becoming growers of these fine Daffodils, as it is a sign that their culture is beginning to spread.

RECENT PLANT PORTRAITS.

D. EDALACANTHUS MACROPHYLLUS (Bot. Mag., t. 6686).—A tall herb; native of the drier forests of the upper part of the Malay Peninsula, flowering there in the dry season. It is also known under the name of *Eranthemum macrophyllum*, and flowers freely in the Palm house at Kew during the winter months. Its flowers are borne on bunches of branching spikes, and are of a delicate lilac colour with a purple lip.

GREVILLEA ANNULIFERA (Bot. Mag., t. 6687).—A rigid, wiry-leaved shrub from Australia, where it is found in the sub-tropical region along the banks of the Murchison River. Its flowers are of a pale sulphur-yellow colour, and are produced in branched bunches on the ends of the shoots. The plant here figured was raised from seed sent by Baron Mueller in 1880, and flowered in the Royal Gardens in July of last year.

SAXIFRAGA LINGULATA var. *COCHLEARIS* (Bot. Mag., t. 6688).—A small white flowered variety of the type indigenous to the alpine regions of the mountains north of Nice and Mentone from the Col de Tenda to Mont Mularé. Sent by Mr. James Atkins, of Painswick, with whom it flowered last June.

UTRICULARIA BIFIDA (Bot. Mag., t. 6689).—A very singular little plant, forming under cultivation mossy matted tufts of leaves in a pot of

sodden sandy soil, above which the wiry rigid stems with yellow flowers, something like those of a miniature *Linaria*, rise in profusion. A native of India, China, Ceylon, Japan, Borneo, and the Philippine Islands. It has also been described by various botanists under the following synonyms, *U. biflora*, *U. diantha*, *U. Wallichiana*, *U. brevicaulis*, and *U. antirrhinoides*.

SPIRANTHES EUPHLEBIA (Bot. Mag., t. 6690).—A singular plant, indigenous to Brazil, whence it was imported by Messrs. Shuttleworth & Carder, who sent it to the Royal Gardens, where it bloomed last November. The habit of growth resembles that of an *Orchis*, and the flowers, of a dull white, veined with brown, are more curious than ornamental.

RODGERSIA PODOPHYLLA (Bot. Mag., t. 6691).—A herbaceous plant from Japan, with foliage resembling one of the *Spiræas*, and producing spikes of small white flowers not unlike those of the common Meadow Sweet. It is said to be nearly allied to the family of *Saxifraga*, and to come between that and the *Astilbes*. It is named after Commodore Rodgers of the American Navy, who discovered it on the shores of Japan. The plant now figured was raised by Messrs. Veitch from seed sent them by their collector, Mr. Maries, and flowered in June last year. The flower-stems are from 2 feet to 3 feet high.

ESCHYNANTHUS PULCHER (*Revue Horticole*, May 1).—A beautiful plant for the decoration of a hanging basket from the roof of a cool stove, with pendulous branches, at the end of each of which are produced from one to four handsome tubular scarlet flowers with a golden blotch on the throat. Also known under the name of *A. Boscianus*. W. E. G.

FERNS.

BEST CULTIVATED FERNS.

(Continued from p. 396.)

DAVALLIA MARGINALIS.—This Australian species is distinct in appearance from any other *Davallia* in cultivation, and deserves a place in all good collections, inasmuch that it makes a very pretty object when grown in a basket. The fronds, which are pinnate, of a light, cheerful green colour, and borne on reddish, slender stalks, are produced on thick underground rhizomes of a rather scaly nature; they are gracefully arched, and produced in quantities. Although deciduous, it is a very interesting species for the cool house.

D. MOOREANA.—A well-known species from Borneo, and whose merits are fully appreciated by all Fern growers, as is amply demonstrated by the fact that huge specimens are to be seen in all flower shows, for which purpose it is admirably adapted. It is a plant of rapid growth, possessing the great advantage, at least from the decorator's point of view, of making a large specimen in a comparatively very small pot. Its beautifully arched quadripinnate fronds grow from 3 feet to 4 feet in length, and from 18 inches to 30 inches in breadth. They are produced on underground rhizomes of moderate thickness, and borne upon slender and pale-coloured stalks. They are of a delightfully pale green colour, and with small, bluntly oblique, numerous pinnæ. They are extremely brittle, and on that account the plant is not used so extensively as it otherwise would be for general decorations. It is, nevertheless, one of the most beautiful Ferns in cultivation, and one of the easiest to manage. Stove.

D. ORNATA.—A robust-growing species from Singapore, producing from a stout and woolly rhizome bold and beautifully arching tripinnate fronds often reaching 3 feet in length, and measuring from 20 inches to 24 inches across at their base; they are of a bright green colour, shining, and of a leathery texture, with very large and sometimes undulated pinnæ. The rhizomes being very flexible, this handsome species is particularly recommended for covering pillars covered with peat or Tree Fern stumps, on which it succeeds admirably. Stove.

D. PARVULA.—This pretty evergreen species, which is found in great abundance in Borneo and Singapore, where some trees have their trunks literally covered with it, is one of the most exquisite gems in cultivation, and although it grows only a few inches high, it is a general favourite amongst lovers of plants, which are attractive either by some peculiar conformation or simply on account of the neatness of their habit. The rhizomes are very slender, covered with bright brown scales; they bear numerous small, flabellate, finely-cut, dark green fronds of a very leathery texture. To be grown in perfection that species requires only a very shallow pan, great care being taken to keep the whole of the rhizomes above ground. Stove.

D. PENTAPHYLLA.—Also a very distinct dwarf-growing kind from the Malay Islands. Its rhizomes, of medium thickness, are covered with a quantity of small brown scales, very bright in colour. They produce pinnate fronds from 10 inches to 12 inches long, with pinnæ of a deep metallic colour, when young turning with age to a dark shining hue and of a leathery texture. It is of easy culture and makes a very handsome basket. It is besides well adapted for growing in the Fern case. Its prettily coloured fronds seldom reach more than 9 inches in length. Stove.

D. POLYANTHA (*divaricata*).—A splendid robust-growing species from Java, having very thick knotty rhizomes, producing very handsome fronds which are four times divided, from 3 feet to 5 feet in length, of a deep red colour when young, gradually changing to a deep shining green; the various hues which are nearly always observable on the plant have a beautiful and very pleasing appearance. The place which suits it best is a projecting rock in the warm fernery where it can show itself in all its beauty. It is also a very shallow rooting species requiring but a few inches of depth of soil to develop itself to perfection. Stove.

D. PULCHELLA.—This very handsome kind, which is probably nothing but a form of *D. canariense*, comes also from the Azores. The rhizomes, in their thickness as well as their mode of growth, bear a great analogy to those of *D. canariense*, but the fronds, which they produce more sparingly, are much more triangular in outline and borne on shorter stalks; it is, in fact, a much more compact-growing plant, the beauty of which lies principally in the minuteness of the pinnules, which are reduced to mere segments, and are of a delightful green. It makes an exceedingly pretty plant when grown in a shallow pan. Greenhouse.

D. PYXIDATA.—A very curious and distinct species from Australia, with rhizomes very flexuose and of a medium size, which possess the singular peculiarity of growing upwards, their points always standing up, and in that respect totally differing from all other *Davallias*. The fronds which are produced on these strange looking dark brown scaled rhizomes are almost perfectly triangular in their outline, and of a very coriaceous texture; they are tripinnate, with pinnules more rounded than in most other kinds, and borne on short erect stalks. The whole of the plant has a very pleasing appearance, as it is of a lively green, although deprived of the rich gloss which is generally found and so much admired on nearly all the other strong-growing kinds. Although of a rather rigid habit, this species is well adapted for baskets on account of the flexibility of its rhizomes. Greenhouse.

D. TENUIFOLIA.—A species very widely distributed over China, Japan, and the East Indies, and which presents many variations as to the length and breadth of its fronds, which usually measure from 8 inches to 15 inches in length, and are erect in habit, ovate-lanceolate in shape, and bipinnatifid, with cuneate pinnæ of a lively green colour. It is totally deprived of rhizomes, all the fronds starting from one central crown; and it, being an evergreen species, makes a splendid specimen for exhibition. Greenhouse. PELLEA.

INDOOR GARDEN.

SELECT PELARGONIUMS.

FOR general purposes the most valuable class of large-flowered Pelargoniums is undoubtedly that which has recently obtained the name of the decorative section, in which are included all that have not the symmetrical shape and regular marking of the show flowers. Another class called Regal Pelargoniums has flowers in which there is an unusual number of petals; of these, Captain Raikes may be cited as an example, but it is difficult—almost impossible, indeed—to say where one set ends and the other begins. Of the large numbers put into commerce every year, many are never heard of after one or two seasons. The following, though sent out within the last three or four years, are still but little known. They have been selected from a great number of varieties, many of them Continental ones, and have been chosen in consequence of some thoroughly distinctive features which stamp them as really different from others in cultivation. Several of them have at some time or other received certificates from the different societies. Among them is Belle de Jour, which attracted a good deal of attention when exhibited. The flowers of this variety, which are pure white and semi-double, are borne in erect, open trusses, so that each individual bloom stands out nearly free of its neighbours; another peculiarity is the flowers do not all expand at the same time, but keep up a kind of succession. Its blossoms, being white and semi-double, will be useful in a cut state, but as a plant it lacks sturdiness; in this respect it resembles an old variety with semi-double flowers (Album plenum) now nearly gone out of cultivation. Two other semi-double kinds, Jeanne d'Arc and Madame Boncharlat, are quite free from this drawback. They are dwarf, but free in growth, and exceedingly floriferous. In colour both are bluish, and resemble each other so closely, that if one is in a collection the other is not required.

Quite a number of free-flowering varieties, in which the blooms are either wholly white or so faintly marked that the colouring is scarcely perceptible, are of Continental origin. Amongst these the best are Lucie Lemoine, Mad. Harmant, and Mad. Charles Koenig; Mad. Marie Knecht is also a good kind. Mad. Thibaut is a very handsome variety, the ground colour being white, blotched with rose in the centre of each petal; its habit, too, is all that can be desired. Volonté Nationale to some extent resembles it, but it is of rather a darker tint. In both of these the edges of the petals are prettily crisped. Another kind with crisped petals, though in a less degree, is Edward Perkins, orange-scarlet with a maroon-coloured spot on the upper petals. In habit and freedom of flowering this is a first-class variety, while its glowing colour stamps it as a promising market kind.

The best of the white crisped flowers of the Duchess of Bedford type I consider to be Maid of Kent, in all respects a good kind. Princess of Wales has a rosy lake colour reticulated with white, and may frequently be seen with a beautiful purplish shade in the centre. The individual blooms are very large, and contain an unusual number of petals, but at times they come what is called washy instead of possessing their ordinary colour; the plant too frequently becomes diseased, points greatly against this variety. Brongniart is a very effective kind, the whole of the five petals being nearly equal in size and each pure white, with a large rosy purple blotch in the centre. Mrs. Potten has a large circular white flower with a velvety crimson blotch. Poiteau, rich purple, with dark spots, has very round flowers and a good habit. Gaston Malet has also very large flowers, which are rosy purple and white in habit; it is dwarf, and upon the whole a fine decorative kind. In Dr. Joseph Nagy the ground colour is white, but a deep maroon blotch extends over half of the petals, giving the flower a very distinct appearance.

Among the brightly coloured flowers, Mountain of Light, one of Turner's show varieties, bears the palm, but its habit is not good. Two striped kinds

sent out by M. Lemoine last season, viz., Oreste et Pylade and Romeo et Juliette, flowered with me, but not sufficiently well to enable me to fully determine the merits of the two. The last appears to have much the better habit, and has also the best marked flower, which is deep rose, striped more or less with carmine. In some blooms the markings are regularly arranged in stripes, while others are nearly self-coloured, in this way resembling an older variety called Queen of Stripes, of which some flowers come beautifully marked, but the bulk only self-coloured. H. P.

DIETES HUTTONI.

THE subject of the accompanying illustration is a very interesting member of its genus, which includes the so-called Iris Robinsoniana, a right royal representative of the family of Iridaceous

Di. t. s. Huttoni. (Flower natural size, plant showing habit of growth.)

plants. The leaves differ from those of every other member of Dietes or Iris, so far as I remember, in not being equitant. They grow to a length of about 3 feet, with a width of three-quarters of an inch, are nearly erect, but curve towards the top and are dark green in colour. The flower-stems are not so long; they are clothed with leafy bracts from base to summit, where several golden flowers are produced in succession. They measure about 2 inches across, and are dark coloured where the black lines occur in the figure. D. Huttoni was sent to Kew from the eastern province of Cape Colony by Mr. Hutton, whose name it bears. It is somewhat allied to D. bicolor, and, as the nearest approach, serves to connect this genus with that of Iris, from which it is scarcely separable by any good botanical character. The flowers are sweetly scented.

In cultivation the several species yield without difficulty to pot culture. They like a rich soil of a loamy character, with a good supply of water while growing. When not growing freely, care must be taken that they do not want water. Red spider is perhaps the greatest enemy with which they have to contend, but owing to their glabrous nature there is no difficulty in removing it. Last

year at Glasnevin I saw a fine clump of D. Huttoni on a narrow border in front of one of the houses where apparently it is quite hardy, but as a rule it must be understood that the species of Dietes are greenhouse plants.

DIETES Mr. Baker has included as a section of the Irises, from which it differs in the flowers having no tubes; it differs from Morea, to which the species have been referred, in being rhizomatous. The species with which we have now to deal are as follows:—

D. COMPRESSA, known more commonly as Morea or Dietes iridoides.—A strong-growing plant with erect sword-shaped leaves of dark green colour and white-yellow blotched flowers, but there are at least two and perhaps three forms quite different in habit which find refuge under this head, and cannot be referred to either of the other species. There is one besides the above with much stronger rhizomes, and another with a more decidedly fan-like arrangement of the leaves, which seems, at least so far, not to have a creeping rhizome at all. This kind I have, and am anxious to get the other two, in order to discover the exact value of the differences which appear to me considerable so far as growth is concerned. Native of the Cape of Good Hope.

D. CATENULATA.—This is a very pretty species, which, so far as I know, is not now in cultivation. It is allied to the last, though perfectly distinct, with white-yellow blotched flowers, distinguished by the absence of hairs from the outer segments of the corolla, their place being supplied by two rows of papillae. The stigmas are blue; the plant is glaucous. A native of the Mauritius.

D. BICOLOR.—This is a beautiful kind, with narrow grassy leaves and full yellow flowers blotched with deep maroon, quite unlike everything else. It is the only one besides D. Huttoni with yellow flowers. A native of the Cape.

D. ROBINSONIANA, though introduced about ten years ago, has not yet flowered. It grows about 6 feet high; in habit it greatly resembles the New Zealand Flax, and bears pure white flowers 4 inches across, relieved, however, with yellow blotches. It is sometimes called "Wedding Flower," a name by no means inappropriate. It is a native of Lord Howe's Island. All the species just named are growing in the Cambridge Botanic Garden, except when stated to the contrary. R. I. LYNCH.

ANTHURIUM WAROCQUEANUM.

SUCH a plant as that mentioned in THE GARDEN (p. 323) may be cut down with safety, provided there are plenty of healthy roots in the Sphagnum around the stem and a good close place in which to put it after that operation is complete. In such cases the aim should be to keep on the safe side as much as possible; therefore should the bulk of Sphagnum and roots be small, some more Moss may be added, and further roots encouraged before removing the head from the parent stem. When that operation is carried out, the plant should be put in a pot just large enough to hold the roots without undue crowding and placed in the shadiest and moistest part of the propagating house. Should there be a close case therein sufficiently large, the plant will be greatly benefited if placed in it for a little time and plunged in a gentle bottom-heat till the roots start, but if placed in the house without that additional protection, it should be dewed over several times a day with the syringe, and besides the shading on the house, shade it also with some sheets of paper when the sun is bright, otherwise some of the old leaves will be apt to turn yellow. I shortened a plant in the way herein described last summer, and by careful management did not lose a single leaf. Choose a dull and cloudy rather than a bright and airy day for such work as that just alluded to. T.

Eranthemum Regnierii.—This was exhibited by M. Regnier, nurseryman, of Fontenay-sous-Bois (Seine), at a recent meeting of the French National Horticultural Society, where it obtained

a first-class certificate. The flowers are produced in large panicles, and are light violet in colour. It was imported from Cochin China, but is said to be a native of Java. This is likely to prove a useful winter flowering plant, and a good companion to its congener, *E. pulchellum*.—J. CORNHILL.

Nicotiana affinis indoors.—Two years ago some seeds of this were procured from Colonel Stuart Wortley, and the result is this year a grand plant $4\frac{1}{2}$ feet in height, having twelve spikes, each bearing about fourteen lovely white flowers, the scent from which in the evening is most delicious. All lovers of flowers should procure some seeds of this plant.—W. M. M.

Fuchsia Phenomenal.—To lovers of large flowers this Fuchsia will at once commend itself, from the very large size of its blooms, which in that respect are quite equal to Champion of the World, at present the largest flowered sort with which I am acquainted. The last named kind is a very free grower, and the flower-stalks are unusually long, conditions that fit it for covering pillars or growing into large specimens, but in the form of small or medium sized plants it is never very effective, as its huge blossoms are but sparingly produced. Phenomenal is not so tall in habit, and when grown in 6-inch pots flowers much more freely than Champion, but even then it is too vigorous to do well in the $4\frac{1}{2}$ -inch pot in which Fuchsias are so largely grown for market. The flower-stalk is of ordinary length, the tube short, and the sepals much reflexed, thus showing off the corolla, which is bluish purple, to good advantage. This variety is of Continental origin.—H. P.

Lapageria shoots dying (J. W.).—I have known the young shoots of Lapagerias to die off through the effects of the sun in the spring coming with full, unobstructed force upon them where the plants have been excited into growth during winter in a house with some fire heat. Where this has been the case the young growth cannot stand the full force of the sun. If the plant in question was turned out last January, especially if planted on the sunny side of the conservatory and has made growth freely, particularly if a little extra heat has been used, the young shoots should be shaded from the sun. In all cases Lapagerias ought to be planted at the shady side of the house in which they are grown; if on a roof they do best on the north side where the sun does not strike them fully. Under any conditions I should advise a little shade being tried until the growth gets better matured. If air was admitted, so as to come directly in contact with the plant during such cold cutting winds as we have had, it is quite possible that may have something to do with the mischief; if the sun came upon them in the way already named, it would aggravate the evil.—T. B.

Passiflora princeps.—There are many kinds of Passion flowers, but this is one of the best. It grows with me in a low span-roofed house, the temperature of which is from 60° to 65° . It is now in an 18-inch pot in fibry loam. In January last I cut it back within 3 feet of the pot, which it requires whenever it gets too thick, and in less than four months it had completely covered the roof, which is 15 feet by 12 feet. It then stopped growing and began to produce beautiful long drooping clusters of scarlet and white flowers, measuring from $1\frac{1}{2}$ feet to 2 feet in length. It seems to flower at almost every joint; I have counted as many as thirty-nine clusters hanging on the plant at once. It commenced to flower with me early in April, and has continued ever since, and very gay it is at the present time. It is a plant that requires but very little attention after it has made its growth in the spring. I never syringe it, and yet it keeps in perfect health and quite free from insects. It is easily propagated; almost any piece indeed inserted in sandy loam will take root, but still it is best to make the young wood into cuttings in spring, insert them and place them in the same temperature as that in which the plant is growing. We find the flowers of this plant valuable for table decoration. Edulis

is also a very serviceable plant, not only on account of the beauty of its flowers, but for its edible fruit.—A. B. C.

GARDEN IN THE HOUSE.

WINDOW GARDENING.*

THE requirements for the successful management of window plants are neither numerous nor difficult; yet more disappointments and failures result than in any other branch of amateur gardening. One of the first requirements is a genuine love for plants, without which the many necessary little attentions are sure to be omitted, and the plants will suffer accordingly. It may be stated as a guiding rule that the greater the care, the greater the success. The majority of plants require all the light it is possible to give them, with as much sunshine as the position and structure of the window will admit. As a rule those plants exposed to the morning sunshine thrive better than those having exposure to the afternoon beams only—this applies particularly to flowering plants. Plants grown for the beauty or elegance of their leaves, as, for example, Palms, Ferns, and Begonias, will thrive in windows which either are not exposed at all to direct sunshine, or for only a short time each day. But the light should be admitted directly to the windows, and not shaded by overhanging roofs. Plants require nutritious soil. The best general soil is turf from a rich pasture, cut about $2\frac{1}{2}$ inches thick, laid closely together until it has somewhat decayed, then broken up and mixed with about one-third very rotten manure or leaf soil. The leaf soil can generally be found in flaky-like forms beneath Oak, Chestnut, or other large trees where standing thickly together. Where such soil cannot be obtained, a good substitute may be found in the rich soil easily obtained from hedge banks and in corners of most fields by the sides of the fence. Those living in cities can always obtain suitable soil from florists.

THE WATERING OF PLANTS is of the greatest importance, and this must be done rightly. Nineteenth of the failures in window gardening can be attributed to improper watering, either too much or too little—in many cases too much. You cannot water any plant by rule of thumb. We frequently hear, "I cannot think how it is my window plants do not do well, for I water them every day." This is likely to be the cause of their not doing well. Whenever you water a plant, always give sufficient to soak the whole mass of soil thoroughly; then do not water it again until it shows signs of dryness on the surface. It may not be for two or three days, or even longer, but no matter; do not water it until you are sure of its being in a slightly dry condition. On the other hand, some plants require water twice a day, especially when the pots are full of roots, and the plants are growing vigorously and flowering profusely. The leaves of plants must be kept clean and free from dust; those with bright, shining leaves and of good size can be wiped clean with a sponge or other soft material. Others with smaller leaves can only be cleaned by being showered overhead either with a sprinkler or syringe, and it should be done once or twice a week. Do not allow plants to stand in water except such as are aquatic. If the water touches the bottom of the pots a good plan is to have a smaller saucer turned upside down for the plant to stand upon within the other saucer, or even small blocks of hard wood or any other material that will hold the bottom of the pot above the water-line, otherwise remember to empty out the water that drains into the saucers. Plants delight in good living, and when the pots become crowded with roots they should be stimulated, but not until then, unless they have been a long time in the same pots, and it is impossible to renew the soil or give larger pots. We are particular in calling attention to this matter of stimulating window plants, from the fact that a theory is now being extensively circulated, to the effect

that plants grown in pots do not require any stimulants, or at the most very few. Our experience is that you can no more grow a plant successfully in a pot in poor or worn-out soil than you can take a crop of corn or any other crop from the same soil ten years in succession without enriching. For stimulants, use 1 ounce of Peruvian guano to 3 gallons of water. Soapsuds or water with ammonia in it that has been used for washing hands are all good; or the top of the soil in each pot may be removed to the depth of from half an inch to 1 inch, a sprinkling of fine bone meal (which can be had at all florists' stores) applied, and then covered up with fresh soil. Besides there are a good many preparations of concentrated manures that are good and easily applied. Plants in warm rooms should be watered with water as warm as the temperature of the room or a little warmer.

INSECT PESTS are a great annoyance, and often cause considerable trouble from the fact that they do harm before being discovered. It is quite safe to subject all plants to an occasional bath of tobacco water, in strength about the colour of strong tea or weak coffee; this can be easily made from the refuse stems from cigar makers or a small package of the common smoking tobacco, by placing it in a pail and pouring over it boiling water, allowing it to stand all night, and then immersing the head of the plant entirely, and holding it so for a few seconds. This will destroy both green fly and red spider; other insects, such as the white cotton-like mealy bug, must be picked off with a sharp-pointed stick, and the very tight-sticking scale-like insects will have to be removed in the same way. In immersing plants, with one hand press tightly on the top of the pot and turn it upside down before holding it over the vessel; this will allow all loose soil to escape and thus keep the liquid clean.

POTTING THE PLANTS.—All plants should have either new pots, or old pots washed perfectly clean inside and out. Broken pieces of pots must be used for drainage by first placing one of good size, with the hollow side downwards, over the hole, then filling in with other pieces to about one-third of the depth; over this place a little rough soil, then put the plant in its place, fill in compactly all round, press tightly so as to have the soil within half an inch of the top in pots of small size, and in larger pots allow an inch for water room, and all plants newly potted should be well soaked so as to be sure the whole is saturated. We have not named any particular time to pot or repot plants, but it is desirable to change the soil at least once a year, and in cases where the pots are already large enough, there is no difficulty in washing away the old soil so as to use the same sized pots again; where plants are potted but once a year, the end of February or beginning of March is the best time; but as plants fill the pots with roots they can be moved into pots a size or two larger at any time.

PLANTS SUITABLE FOR WINDOWS.—To obtain the best results we must divide our collection into two sections—the first to embrace such as will do well in rooms where the temperature exceeds 65° Fahr., and the second where the temperature does not exceed 65° nor fall lower than 40° . This must be understood to mean where the heat is artificial and not sun heat; and we may say a slight variation for a few hours at a time will not be injurious should the temperature rise or fall. First on our list stand Begonias. These embrace several distinct characteristics. The shrubby flowering species, generally with bright, clean leaves, give general satisfaction, and if properly watered and placed where they can have a little sun, flower persistently the whole of the winter; such as Saundersoni, hybrida multiflora, Weltoniensis, semperflorens, the brilliant B. rubra and insignis should be included in a limited collection. These do not include nearly all of this section, but are easily managed. Another class of Begonias are the Rex type, with beautifully marked leaves of all shades of green and silvery white. These require a rather shady position and a moist

* Paper read at the March meeting of the New York Horticultural Society by Mr. John Thorpe.

atmosphere; in fact, they must have a good degree of moisture atmospherically or they are unsatisfactory. They are impatient if subjected to too much water at the roots or too much dust. Caladiums, with many-coloured, spotted, striped, and mottled leaves, are very handsome plants for summer, and can be started in small pots in March in the warmest corner, repotted as they grow into pots of 4 inches or 5 inches in diameter, and by the time other plants have to be removed out of doors these will be fine objects all summer. Coleus and Achyranthes are valuable plants for warm rooms, and strong tops of them can be easily rooted. Crotons have not as yet been employed for window plants to the extent they deserve. Their richly marked leaves, elegant forms, and variable shapes are always attractive. They delight in rich soil, a high temperature, and moderate light; they should be frequently cleaned, either by sprinkling, bathing, or sponging; they may either be kept inside all summer, or after June 1 they may be plunged in some shady, warm corner outside until the beginning of September. Any straggling shoots should be pinched or cut off from time to time, thus producing a bushy growth. The varieties interruptum, irregulare, variegatum, and pictum are the best. Draceas are elegant plants and easily managed. The varieties terminalis, Guilfoylei, Cooperi, and amabilis are grown in great numbers for window plants, and if treated as advised for Crotons they will give the same satisfactory results. Ferns succeed in the shadiest windows; they require but little attention, and are always graceful and cheering. They must be kept well supplied with water, and occasionally bathed or syringed. This is about all the cultivation required. A few beautiful varieties are *Adiantum cuneatum*, *Farleyense*, *gracillimum* and *trapeziforme*, *Davallia tenuifolia*, *Lomaria gibba*, *Microlepia hirta cristata*, *Nephrolepis davallioides furcans* and *Pteris cretica albolineata*, not forgetting a few varieties of *Selaginellas* or *Lycopodiums*. The *Ficus elastica* or India-rubber tree is well known, and might almost be called the indestructible plant. With its bold and leathery leaves, its free and noble carriage, it bids defiance to dust and smoke alike, provided always it has plenty to drink, with occasionally stimulants added. These remarks also apply to *Aspidistra lurida*, one the best of all room plants. Palms, the aristocracy among fine foliaged plants, are mostly very easy to manage, requiring a good deal of water and not necessarily very large pots; they thrive well in a partially shaded window. A few fine kinds are *Areca lutescens*, *Caryota urens*, *Cocos Weddelliana*, *Latania borbonica*, and *Oreodoxa regia*. They can be used for various purposes of table decoration.

THE SECOND SECTION contains a more extended list of flowering plants and not so large a list of fine foliage plants. Beginning with *Abutilons*, we have a class of elegant free-flowering winter-blooming plants, embracing white, yellow, orange, and deep red. They will thrive in a partially shaded window, and adapt themselves to any mode of training. They can be trimmed into either standard or any other form, and will flower continuously. Azaleas are very beautiful, easily managed, but rather impatient if subjected to a dry atmosphere or allowed to get dry; in fact, they should never be allowed to get dry at the roots either winter or summer. A frequent bath, immersing plant and pot, is a safeguard against drought and otherwise beneficial. A partially shaded window and a shady spot out of doors in summer will give them about all they require. As to varieties, there are no poor ones, and most florists have a good selection. This brings us to another very popular flower—the *Camellia*—one of the very easiest plants to manage, but unfortunately generally a rather unsatisfactory window plant, from the fact of its being so very conservative. It does not show any abuse at the moment, and not even for months; but, alas! it breaks down, and its apparent fine large buds drop off one by one until none are left. This, in nine cases out of ten, is from the plant being allowed to suffer for want of water in the summer time. Those curious enough to open one of the fallen buds will find generally the outside of the

flower quite fresh, but the centre always discoloured and dead. With well-drained pots it is almost impossible to give *Camellias* too much water in summer, and the same treatment and position as advised for Azaleas will exactly suit *Camellias*. Calla Lily (*Richardia aethiopica*) is another very popular window plant, and yet not very generally successfully managed. Those having plants of it will do well to keep them growing in a light, sunny window; if they have not flowered, do not lose patience and set them in the background; bear with them until the 1st of May; then find some shaded, damp corner in the garden; in this plunge your plant over the rim of the pot; about twice a week during the summer carry along with you a watering-can of soapy water and give your Calla a dose of it. Towards the middle of September lift them, and if the pot appears too small for the plant, get a pot one or two sizes larger; turn it out, and place it in the larger pot without breaking the roots; then stand it in the lightest sunny window. As it begins to grow give it plenty of water and often some stimulants, and by Christmas, if these directions are followed, you are sure to have flowers. After the flower-buds are in sight, you can place the plant in a very warm position without injury. Carnations are always favourites, and should be very satisfactory plants; they can always be had established in pots in the autumn. They delight in a rich soil, a rather low temperature, and plenty of sun. Those desiring to grow their own plants should plant small ones in the open ground in May in a sunny position, occasionally cutting off their tops to make them bushy, until the end of July, after which they should be allowed to grow. At the beginning of September lift them carefully with balls of earth and place them in pots well drained; put them in some shady place, and after they begin to grow, and before frost, remove them into the house. A few *Chrysanthemums* should be planted at the same time as the Carnations, and subjected to precisely the same treatment, or a few can be plunged in pots and watered as often as required. Those who have a window should have some of these, the most beautiful of all autumn flowers. *Daphne indica*, two varieties, are easily managed, and perhaps the most deliciously perfumed winter-flowering plants we have, requiring about the same treatment as Azaleas. Fuchsias can be made to flower quite early in the spring. They require good drainage, a light, porous soil, a somewhat sunny position in winter, slight shade in summer, and a rather moist atmosphere. Geraniums (these are really *Pelargoniums*, but we seem to have got so used to the name *Geranium*, it is a hard matter to believe any other) are for a light, sunny window, where the temperature can be kept about 55° to 60°, the best of all winter-flowering plants, and all growers should have among their collection both double and single varieties, especially some of the finer forms of the single kinds. They are so easily managed and so continuously in flower, it would seem there ought to be no dearth of flowers where there are half a dozen kinds. Some window gardeners expect to have their windows gay all winter and their flower gardens gay all summer with the same plants. This cannot be done; those plants intended for winter flowering should be nicely rooted plants in May, then potted into small pots and plunged in the open ground, the flowers to be kept picked off all summer. About the middle of August they should be potted into good soil in well-drained pots of 4 inches or 5 inches in diameter, placed in some spot where they will have a little sun morning or evening, but not plunged as before. After the beginning of September take them inside, and place them in the sunniest window you have, water well, and carefully turn the plants round from time to time to keep them in good shape; as the pots get full of roots, give a little stimulant at least once a week, and there will be no dearth of flowers. If old plants are kept over, they should not be allowed to flower during the summer, but treated as advised for young plants.

MISCELLANEOUS PLANTS.—Those desirous of a few more Ferns for a cool room should add to

the list already given—*Cyrtomium Fortunei*, *Lastrea aristata variegata*, *Nephrolepis tuberosa*, *Pteris argyrea* and *tremula*. Other Palms could be added also for growing in a cold window, as *Areca rubra*, the three *Chamærops*, *excelsa*, *Fortunei*, and *humilis*; *Corypha australis*, and *Seafortia elegans*. Chinese *Primulas*, *Cyclamens*, and *Cinerarias* are good plants, easily obtained, and requiring about the same treatment as that recommended for Geraniums after being brought into the house. These do not exhaust half the window plants available. There are a few others which should be included in our list, such as Ivy, German Ivy, *Lygodium scandens*, and *Smilax* as climbers. And for basket and bracket plants use *Othonna crassifolia*, the different *Tradescantias*, *Creeping Jenny*, and several other kinds that will present themselves to the enthusiastic window gardener. The disposition and training of the various plants may be left to the cultivator, but it is best always to consult the general habit of the plant, and not to force it into a shape and position that prevent healthy growth and development. As with the training so with the grouping or arrangement of plants in baskets, stands or jardinières, it can be left to individual taste. Where it is not desirable to disturb plants by repotting, they can be placed inside larger pots and the interstices filled up with either Moss or fine soil. On all favourable opportunities air should be admitted for a few minutes or longer each day; but as window plants are not expected to have all their requirements as if grown in a structure expressly for that purpose, we must do the best we can under the circumstances. I have made no mention of bulbous plants, but I may add that many of these are also very beautiful.

DALKEITH PARK,

ONE of the seats of the Duke of Buccleuch, lies about six miles south-east of Edinburgh, the palace, as it is called, being a large building with walls in some places 9 feet thick, and overlooking the vale of the north Esk. The chief feature of the place is its glorious forest-like park, or rather park-like forest. There is this about Dalkeith which must commend its noble owner to the thanks of the community, viz., its gardens are open to visitors every day but Sunday without let or hindrance, and the house and park are also open every Wednesday and Saturday in the absence of the family. Mile after mile of rugged picturesque walks may be traversed—now by the river roaring over its rocky bed, and repeatedly crossed by massive stone and rustic bridges; now on the greensward, and then on carriage drives under patriarchal Oaks. Through the forest glades herds of deer roam and dart across the path, whilst the underwood swarms with pheasants and woodland songsters; the wild duck coming here from further north to breed is already mated, and can be seen wherever there is water. Everywhere sylvan beauty reigns. The forests of Oak have quite an ancestral history. Here the Duchess Anne planted Oaks 200 years ago on the principle of “aye be stickin’ in a tree,” whilst a hundred years later Duke Henry still planted and replaced those missing from the previous century. As for the more antiquated monarchs of the wood, they are prehistoric; four or five centuries have rolled over their tangled heads. One ancient Oak measured 20 feet in circumference at more than 5 feet up the bole; near it was a strange alliance between youth and age; in a crevice of an Oak was a Strawberry plant in full bloom (April 14), the seed having been deposited there by some thrush or blackbird. Such a way does Nature sometimes adopt when she wishes to transport or transplant her productions. Oaks, however, are not the only giants in the park; three Cedars are each over 80 feet high, and one of them has a circumference of 18 feet for 20 feet of its height. Of Limes some are upwards of 130 feet high; there is also a Beech 132 feet, and a Wych Elm 130 feet from base to summit. There is here the finest specimen in Scotland of the Maiden-hair tree (*Salisburia adiantifolia*); it is 45 feet high. Near it stands the conservatory, an elaborately carved

stone building erected by Burns, the famous Scottish architect. One noteworthy feature is a grove of Limes a quarter of a mile long, containing over 300 trees, and as these average 100 feet high, meeting overhead, this "aisle of Nature's Gothic" (the Monk's Walk, as it is called) is something to be remembered. Coming to

THE GARDENS by way of winding walks, margined with Narcissi, Daffodils, and Snowdrops, which have been glorious amongst the close turf under the trees, there is a freak of Nature, or art perhaps, worth recording. The lowermost branch of a fine Holly tree has been bent until a branchlet, penetrating the ground, has rooted and grown into a stem as thick as one's arm. It tapers from the ground upwards and bears branches which grow upwards. This prop belonging to the depending branch is some distance from the main stem.

ROSE GROWERS who visit the gardens in July and August may have a glorious promenade under an arcade of Roses 100 yards in length, terminated by a true Rose bower; whilst indoors the Duchesse de Vallombrosa, Comtesse d'Oxford, Victor Verdier, and a host of others already offer floral tributes. "Old Gloire" is a sheet of bloom overhead, flanked by Maréchal Niel, one of the hardiest of Tea Roses. The "black fortnight" in March has not been so disastrous in Scotland as in Yorkshire; while in the latter district there was 20° of frost on March 9, only 8° of frost were noted as the lowest in March at the Royal Botanic Gardens, Edinburgh, on the 15th, Teas and Hybrid Perpetual Roses being reported as only slightly injured. Frequently we came across a long border, a hundred yards or so in extent, or a large bed, filled with seedling Polyanthus, and it is surprising how effective are their varied blooms when massed; all hues may be found here, from deepest purple to paper white. A house 100 feet long is staged sharply up to 12 feet high, and this is a dense mass of Rhododendrons and Azaleas in bloom, whilst a novel break up of monotony is obtained by interspersing in this shrub bank Arum Lilies, which protrude their white spathes here and there through the bushes with charming effect. Bananas are a great feature here; they range up to 15 feet high, and have stems almost as thick as a man's body, not one being over twelve months old; they have quite a tropical effect planted out in soil covered with the pretty *Gymnostachyum Verschaffelti*. The fine Orchids that are here are grown well; noticeable amongst them were masses of *Dendrobium fimbriatum*, *D. chrysotoxum*, *Phalænopsis amabilis*, *Cattleya Skinneri*, *Cypripedium Dayanum*, *Oncidium Phillipsi*, and *Vanda snavis*, these being all in bloom; *Vanda teres*, a fine specimen which blooms regularly here, is bound upon *Spagnum* to a charred sapling. In another house an iron tank is devoted to the

CAPE PONDWEED AND ARUM LILIES, close by being a fine plant of *Ouvirandra fenestralis*, with its curious perforated leaves. Camellias are associated with gorgeous masses of Tulips, Narcissi, and Hyacinths. The next house is devoted entirely to Heaths, and deserves more time than a casual visitor can bestow on it, but further on is a pleasing utilitarian bit of colour—a white wall covered with the green leaves and some showy crimson fruit of Tomatoes. For the growth of Ferns, virgin cork is freely used, nailed to walls on which the *Ficus repens* creeps picturesquely. There is here a pinery 80 yards long with fruit in various stages of development and a *Stephanotis floribunda* trained along its roof, and in a low sunk house saturated with moisture *Droseras* are flourishing. Amongst others I noticed the curious *D. pinnata*, a kind that sends out a smooth stem from 9 inches to 1 foot long, and then dichotomises, the forks being covered with the hairs and secretion peculiar to this tribe. In the same house are *Gardenias*, *Francisceas*, and a fine specimen of *Anthurium Andreanum* bearing seven fine flowers, the spathes of which measure 6 inches by 5 inches. The display of flowers was confined to the last house visited—a long low one full of *Cinerarias* in all shades of purple, blue, and mauve, varied by golden Paris Daisies, and the scent of Mignonette, which filled

the place, completing and perfecting the trinity of colour, form, and odour.

R. A. H. G.

SPRING FLOWERS IN CALIFORNIA.

APRIL in California! What a dream of delight the words recall to the fortunate traveller whose times and seasons have been so happily ordered as to bring him to the Granite State at this favoured season; for all these Western States are like different worlds, according as we see them in the green loveliness of their fresh spring-time, or when the long summer's drought has transformed the flowery pastures into broad plains of yellow sundried hay and withered plants, all smothered in stifling dust. I had, therefore, good cause to deem myself fortunate, when, owing to prolonged detention in the beautiful isles of the South Pacific, I landed at San Francisco on Easter morning, and received my first impressions of the New World from its exquisitely decorated churches, with their lavish display of flowers. Each church in the great city strove to outdo its neighbour in its profusion of Roses and pure white Lilies—chiefly the Calla Lily, which we call Arum. Throughout California the afternoon of Easter Day is the children's floral festival, and thousands of happy little ones march in procession, with gay banners and offerings of flowers, to take part in a joyous choral festival, and to present their gifts of lovely fragrant flowers—perhaps also of money—for the poor and suffering. After this glimpse of what Californian gardens can produce, we made various expeditions in the neighbourhood, and everywhere the prominent object was the wealth of wild flowers. We drove for miles through Lupine scrub—hardy, perennial Lupines, indigenous to California, and able to flourish on the driest sand. So their growth has been greatly encouraged on the desolate sand dunes on which the great city has sprung up; and these pioneer Lupines are doing a mighty work in reclaiming thousands of acres of the arid, shifting sands. Each bush bears countless spikes of blossom, pink, lilac, white, blue, pale lemon, or orange colour; and besides these shrub Lupines, all other varieties grow abundantly—small lemon-coloured flowers, large succulent blue Lupines, and all manner of dwarfs. Elsewhere we passed by patches of intensely blue Larkspur, and a scarlet flower called Painted Brush, and many other beautiful wild flowers. But, above all, our eyes rested in wonder on broad sheets of the most vivid orange, scattered here and there over the green pasture hills. We were told it was the California Poppy, and, on nearer inspection, recognised the familiar *Eschscholtzia* of our own gardens, which here, in its native land, attains a luxuriance unrivalled in exile. But not till we reached the flower-strewn slopes of the coast range could we fairly lay claim to having some idea of the glories of this great floral region. Here hills and meadows were all alike ablaze with bright-hued blossoms, scarlet and gold, pink white, and lemon colour, blue and purple, of every shade. Flames of vivid colour lighted up the forest glades, and brightened the darkest ravines or the greenest Grass slopes; scarlet and blue Larkspurs, Musk and other *Mimulus*s, blue *Nemophila* and scarlet Columbines, dwarf Sunflowers and *Fritillaria*, Heartsease and Forget-me-not, golden *Ranunculus* and dwarf blue Iris—these, and a multitude of flowers familiar to us in gardens, here overspread the land at their own sweet will. In one morning's ramble I collected upwards of a hundred different flowers, and I was told that in the course of a Californian spring and summer I might find no fewer than 600 species! It was a great delight to me to find the jovial round face of the familiar Sunflower, heaving a cheery welcome to its Californian birthplace; but we saw only a few blossoms. I was told, however, that there are tracts in the mountain districts to the south where, for miles and miles, successive ridges gleam like gold, owing to the myriads of these gigantic yellow Daisies, so closely packed that there is no green to be seen, only a sheet of saffron hue. The same glory overspreads Southern

Colorado, where purple Asters also abound, and both grow so freely that they even spring up from the turf sods with which the miners roof their huts, giving quite an æsthetic touch to the dingy camps.

Beautiful as were the plains in their robes of flower-embroidered verdure, I craved to reach the beautiful Sierra Nevada; and, hearing that the rapid melting of the snows had opened the roads to the far-famed Yosemite Valley, I resolved to start without delay. One afternoon on the railway and two long days of coaching brought us to the forest belt. The railway ran us along a small portion of the vast Wheat field which now extends well-nigh 600 miles from north to south. However dear to the farmer, it is not attractive to the lover of beautiful, uncultivated Nature, and I was glad to escape from its monotony and arrive at a region of gently undulating hills, all clothed with rich tall Grass of a peculiarly lovely light green, ideal pastures where happy cattle were luxuriating; and here, too, the beautiful Grass was but a groundwork whereon were showered masses of vivid crimson and purple, white, scarlet, and gold. Onward we toiled, uphill and down, winding round about among the foothills, which in places are densely clothed with chapparal (*i.e.*, brushwood, with a large proportion of flowering shrubs), and elsewhere are grassy and park-like, adorned with fine clumps of Buck-eye and live Oak—in other words, Californian Horse Chestnut and Ilex. And, far and near, the grassy slopes were tinged with rainbow hues where the bright sunlight played on banks of wild flowers. As we reached the higher levels, we found deep banks of snow lying in places; but even close by these some kindly blossoms had contrived to expand, and in the shelter of the great Pine forest I found some beautiful specimens of a plant altogether new to me—*Sarcodes sanguinea*, a strange, bright scarlet-crimson blossom, like a very fleshy Hyacinth. It is called the Snow flower, because it rises right out of the earth as soon as ever the snow melts, after the manner of our Snowdrop; but instead of being enfolded in smooth green leaves, each crimson bell is wrapped in a crimson leaflet, which uncurls as it rises above the earth, forming a sort of hyacinthine pyramid of blossom 8 inches in height. It has only 2 inches or 3 inches of thick stem, and really suggests little tongues of flame darting out of the newly-thawed earth, quite close to snowdrifts. When we reached the higher levels, and caught sight of a succession of grand mountain summits all robed in dazzling white, we fully realised our good fortune in having arrived while there was yet sufficient snow to let us see the Sierra Nevada* in its true character.—*Cornhill*.

Noble Pansies.—The thanks of those who love fine Pansies are due to Messrs. Vilmorin, of Paris, for seed they supply (*Pensées à grandes macules*), producing a large proportion of such flowers as those enclosed. A florist would doubtless call them "coarse" and "rough" with their waved edges and large size, but all who value flowers for their true beauty cannot fail to find them grand flowers. Some blooms in the same strain have the more "orthodox" qualities of moderate size, firm substance, flatness of flower, and regularity of blotching and colouring. These great Pansies, besides their garden beauty, are of high value for cutting; the growth is so luxuriant that one may cut whole sprays a foot long, with abundance of fine foliage, and make bouquets of Pansies for indoor decoration of noble size and unusual aspect, a pleasant contrast to the short-stalked bunches of Heartsease one usually sees. The packet of seed was sown in the middle of May, the seedlings transplanted two months later to well-prepared beds, and finally placed in the beginning of October in an open, but sheltered position.—*G. J., Surrey*.

* * The finest Pansies we have seen, we think. To call such flowers "coarse" is no sign of wisdom or taste! It is the formal stiff flowers, if such there be, that deserve like epithets. But our ex-

* Sierra Nevada, range of snow.

perience of the Pansy is that, off the exhibition bench, it never really conforms to the circular ideal.

GARDEN DESIGN.

DESIGN IN TOWN GARDENS.

It is the general impression that the laying out of

it need hardly be said, should always be a cardinal rule in designing town and other small gardens, and another important point is to know how to plant, how much to put in, and when to stop planting. If too much crowded, the place looks smaller than it really is; on the other hand, if too little is done in the way of planting, the smallness of the garden becomes too evident. Above all great care is required in the matter of selecting

few simple beds for gay flowers that would be effective from the windows. The border beyond is one of the best positions that could be chosen for showy hardy flowers, and it could be kept gay from March to October by a judicious selection. For example, the finest Daffodils and other Narcissi would make the border gay through March, April, and May. Intermingled with these should be a few plants of Pæony, the tender red foliage of which would contrast charmingly with the yellow and white Narcissi. A successional crop of bloom could be obtained from blue Delphiniums and Evening Primroses, both of which succeed admirably in London; and these again could be succeeded by Phloxes and Tritomas, which latter would carry the season on to autumn, after which open-air flowers are not looked for in London.

A glance at the plan will show how well every plant is placed, so as to be seen to the best advantage, and, what is important, all are not seen from any one point. For example, the round flower-beds at the angles of the lawn are screened by the shrubs, and in following the path they come into view as a surprise. The preponderance of deciduous trees and shrubs and the paucity of evergreens is conspicuous, and the selection includes things not commonly seen in country gardens, such as the snowy Mespilus (*Amelanchier canadensis*), *Pyrus vestita*, Maiden-hair tree (*Salisburia*), Scarlet Maple, and others.

W. GOLDRING.

FLOWER GARDEN.

APRIL FLOWERS.

AMONGST those well worth growing the following may be included, and most of them are now little, if at all, the worse for the hardships they have gone through this spring. *Arnebia echioides*, the Prophet Flower, is already in blossom. It is curious to watch, day by day, the gradual disappearance of the black spots on its yellow flowers as they grow old. The white *Fritillaria contorta* is somewhat finer than the white form of *F. Meleagris*. *F. lutea* is a distinct kind; and the quaint *F. nigra*, when a good clump of it is in blossom, is perhaps worth a place on the rockery, though neither kind can be called pretty. *Mertensia virginica* surpasses the *Pulmonaria* in the beauty of its blue flowers, but *P. saccharata* and *P. mollis* are good spring plants. *Menziesia empetriformis* with the pink and white Mediterranean Heaths have replaced *Erica carnea*. *Saxifraga Wallacei* and the little red-flowered *S. muscoides atropurpurea* are amongst the earliest of the mossy *Saxifragas* here. *Veronica pectinata*, pink and blue, is beginning to flower, and also a pale mauve kind from the College Gardens, Dublin.

The pale yellow *Uvularia grandiflora*, though not effective, is sufficiently distinct to make a clump of it worth growing, and those who care for curious flowers will not grudge a spot for *Allium paradoxum*, with most of its flowers replaced by bulbils, or *Tulipa cornuta* with its pointed, horn-like flowers. *Tulipa Celsiana* is remarkable for having its yellow, slightly sweet-scented flowers bent to one side, and sometimes two on a stem; and *T. pulchella*, one of the smallest of Tulips, claims a place amongst dwarf alpine plants. When grown in good clumps, *Scilla italica*, though less pretty than the early *Scillas*, is very effective. Like many other flowers, its beauty cannot be fairly judged of till it is sufficiently established to blossom well. The same may be said of *Adonis vernalis*, a small plant of which with about eighteen glossy yellow flowers is a pretty sight just now in sunshine. *Ornithogalum nutans* is flowering well this year. It is unaccountable that it is not more largely grown. No plant requires less care, and its silvery green-tinted blossoms are unlike any others that I know of, and especially good as cut flowers. No rockery should be without the dark purple *Aubrietia Hendersoni*; *A. Eyrei* and *A. grandiflora* are also excellent varieties. *Arctostaphylos californica*, a somewhat rare alpine shrub, grows well over a stone; its pink Heath-like flowers are pretty, but it does not blossom freely here. Primroses and various other Pri-

A London garden.

small gardens is a simple matter, but in reality more skill and thought are required in designing a garden in a limited area than one of large size, particularly in towns where the number of trees and shrubs that thrive perfectly is not great. It is simply a question of making the most of a small space. We have only to look at the average London villa garden to see how miserably designed it is in nine cases in ten. Usually we find the place, be it ever so small, cut up in all directions by paths, and these commonly tortuous, the impression doubtless being that such windings and twistings are picturesque in appearance. Often, too, we see such gardens carved out into congeries of beds generally fantastic in outline and crammed full of unsuitable plants. Simplicity,

suitable plants, for however good the design may be, it will be spoiled if the choice of trees and shrubs is bad.

An example of what may be considered good design in town gardens is shown in the annexed plan, which represents the Duke of Buccleuch's garden, at Montague House, on the Thames Embankment, in, it may be said, the heart of London. This garden was designed some years ago by Mr. Marnock, and, as may be seen, it is treated in his usual simple and effective style. The plan speaks for itself. The letter B represents the front of the mansion, with the windows overlooking the garden and the Thames. From the terrace to the boundary wall at A the surface is level with the exception of a gentle rise, on which were placed a

mulas keep well-nigh at the head of the list of hardy plants in April both in beauty and in interest, and will continue to do so well into the summer. Plants of *P. rosea* have blossomed in succession for about two months; it is certainly one of the most beautiful of the many hardy plants introduced within the last few years. Another Indian plant, *Andromeda fastigiata*, seems to like a bog bed as much as this *Primula* does. A very small plant protected by a cloche is flowering well. Queen Anne's Jonquil (*Narcissus odorus fl.-pl.*) is an excellent kind for spring bedding, and, judging from the effect of a few scattered bunches of Queen Anne's Daffodil (*N. capax*), it would be as good, if not a better bedding kind, much paler yellow than the former, and earlier, as it is now out of blossom here. The colouring of *Myosotis elegantissima* is peculiarly soft and pretty; and *Myosotis dissitiflora*, which, except in sheltered nooks, suffered much this season, is now in full beauty, most of it having already recovered. The exquisite colour of a mass of this Forget-me-not is, perhaps, best seen just as the light begins to fade. Where the climate suits it, it would not be easy to find a better bedding plant amongst either hardy or half-hardy flowers; but for brilliancy and rich depth of colour no mass of flowers can well surpass beds of *Anemone fulgens* seen in full sunshine. I send two or three blossoms to show that bronze-leaved *Pelargoniums* grown over their roots during summer do not lessen the luxuriance of these *Anemones*, though this plan, perhaps, makes them begin to flower a little later than those grown in beds not so shaded in summer. Double Daisies have suffered this year, but, in spite of all they have gone through, they help to keep up the brightness of the spring garden, which even such a season has not succeeded in destroying. How can anyone who lives in the country in spring be content to have flower beds like miniature ploughed fields for eight months in the year instead of the constant succession of lovely flowers which may be grown in most gardens from early spring to late autumn?

Knockmullen, Gorey, Ireland. C. M. OWEN.

MORE WALL PLANTS.

THE list of evergreen plants suitable for covering walls mentioned in THE GARDEN (pp. 81-82) might be much extended, especially if intended for our southern counties. A stretch of wall came under my observation now many years ago at Bicton, the effect of which was really grand during the summer months. The plants with which this particular piece of wall was covered were *Magnolia fuscata*, the highly fragrant blossoms of which were freely produced each season, and in spring filled the surrounding air with their perfume. Although not showy as regards the flowers, the foliage is neat and cheerful, and the habit of the plant such as to clothe the wall densely. No pruning whatever is required, unless it be to thin out the weak shoots a little. *Edwardia microphylla* was there too, its small pinnate foliage and twiggy growth being very different from those of most subjects so employed. This plant used to produce its yellow pea-shaped flowers nearly every year. *Ceanothus azureus* was the third occupant, and very beautiful it was; but still it had, if possible, to yield the palm to a large plant of *Solanum crispum*, a free-growing ligneous species, evergreen during mild winters, and liable, if the weather is severe, to lose its leaves. The plant at Bicton grew vigorously; it had in the first place been secured closely to the wall until the required space was covered and then allowed to grow without restraint; the consequence was that the branches fell in a graceful manner from the wall and clothed it with a perfect mass of greenery. During summer it produced flowers freely in large terminal corymbs, and when in bloom it was a sight to be remembered. The flowers are of a bright bluish lilac colour with prominent yellow anthers. Other additions that occur to me are *Ligustrum japonicum* and *lucidum*, two dark green shining leaved Evergreens, perfectly hardy, free in growth, and in summer studded with light open panicles of white fragrant flowers. *Berberidopsis corallina* is a pretty

climber, not too vigorous in growth for low walls. Its foliage is ornamental, and the pendulous blossoms, which are bright crimson, are produced freely. *Akebia quinata*, which we are told by Fortune festoons the hedges and trees in some parts of China, is such a singular plant when in flower that mention of it must not be omitted. It is sufficiently hardy to survive London winters against a south wall, and thus situated flowers freely. It is a slender climbing plant with pale green divided leaves and deep claret coloured flowers, the seed-bearing ones being much more prominent than the pollen bearers. *Garrya elliptica*, though it will grow as a bush, likes a wall. Thus favoured, its dark green leathery foliage attains a larger size than in the open, and its long pendulous catkins render it distinct from all its associates. *Viburnum Awafurki* has leaves fully as large as those of the Laurel and massive in character. It therefore clothes a wall densely.

Some of the *Pittosporums* might also be added, as, for instance, *P. crassifolium*, a kind with light-green foliage, tomentose beneath, and *Tobira*, the leaves of which are of a very pale hue, thus affording a pleasing contrast to the almost black colour of the young shoots. Of this there is a variety, the foliage of which is variegated. The *Pittosporums* are about as hardy as the Myrtle, and the same may be said of *Leptospermum scoparium*. The *Leptospermums* are represented by several species, but their general character is the same. They are medium-growing slender twiggy shrubs, with lanceolate leaves and small Myrtle-like flowers, which are borne in great profusion. In sheltered spots along the south and west of England the *Leptospermums* grow and flower well.

FABIANA IMBRICATA grows vigorously and flowers freely in our warmer coast districts. It is a bright green, cheerful looking shrub with small foliage and pure white tubular flowers, in all respects somewhat resembling a Heath, although it belongs to quite a different order, viz., Solanaceae. *Passiflora cœrulea* is rapid in growth, and even if cut back during winter it soon recovers. Its flowers, which continue to open all through the summer, are favourites with most people. *Stauntonia latifolia* and *hexaphylla* are two dark green divided-leaved climbers of rapid growth and nearly hardy, the shelter of the wall being quite sufficient protection for them during ordinary winters. The different *Azaras*, too, form pretty wall plants, the foliage of all being dense and solid in texture. Of these Chilean shrubs, *Azara microphylla* has small dark green leaves arranged in two rows; the branchlets are also produced at regular distances apart and droop gracefully, the effect of the whole being that each branch presents the appearance of the frond of a Fern. *Azara integrifolia* has somewhat larger leaves and is less graceful in habit, but still a handsome shrub. Of this there is a variegated variety in which the leaves are deeply edged with yellow, the whole plant being very bright and cheerful, but rather slow growing. Not so the next, *A. Gilliesii*, which is a large, strong growing kind. Its leaves are thick, dark green, and as much as 4 inches or 5 inches long and from 2 inches to 3 inches broad. The flowers are produced from the axils of the leaves during the winter months; in colour they are bright yellow, and resemble small catkins. The evergreen *Ampelopsis striata* is a pretty climber, almost if not quite hardy near London. Its leaves are very deep green, and the leaf-stalks brownish. It is free in growth, and when established, clings to walls without support. *Camellias* make good wall plants even if the flowers are left out of consideration, as the foliage is so handsome and dense. Of course the flowers are often cut off by frost, yet in sheltered spots such is far from being invariably the case, especially if only the hardiest kinds are so planted. For outdoor planting the old single red is one of the best, as it flowers freely, is among the most hardy, and the foliage is better than that of the majority of the others.

GOOD SUBJECTS FOR LOW WALLS are the Mexican *Choisya ternata*, which produces pretty white

flowers in spring, and *Olearia Haasti*, a New Zealand composite which flowers in summer. Like the last, its blossoms are white and individually small, but borne in clusters and in such numbers as to cover the plant. They last in beauty a long time, whether cut or allowed to remain undisturbed. The shrubby *Veronicas* are also suitable free-blooming plants for low walls. Ivies, of course, must not be omitted. *Euonymus latifolius*, a deciduous shrub, is nearly related to the common Spindle Tree (*E. europæus*), but far more ornamental, especially as regards its fruits, as when the capsules open the bright orange-coloured seeds hang thereupon suspended by slender filaments, and remain in that condition a long time. It is a valuable shrub, but scarcely adapted for walls, while all the varieties of *Euonymus japonicus* are very handsome trained thereon. To the broad silver-leaved form of *E. japonicus* might with advantage be added the deep golden variegated kind. *Crataegus Pyracantha Lælandi* has larger and brighter berries than those of the ordinary *Pyracantha*, that is if the true *Lælandi* is obtained, as many sold under that name are nothing but the common one. To *Escallonia macrantha* in the south of England may be added *E. montevidensis*, a vigorous growing shrub, which bears large terminal clusters of white flowers. This *Escallonia* pushes forth stout shoots from the base of the plant with great freedom, and it is on these gross branches that the finest flowers are borne. There are several species of *Smilax* quite hardy, and very distinct from any of the other plants here mentioned, which will cover walls from 6 feet to 10 feet high with a profusion of bright glossy foliage. Among them may be mentioned *S. tamnoides*, recently figured in THE GARDEN, *S. aspera* and its mottled-leaved variety, and *S. rotundifolia*. To the list of

DECIDUOUS FLOWERING WALL PLANTS (p. 138) may be added *Forsythia suspensa*, a shrub which should on no account be omitted, as its bright yellow flowers are produced so early in the spring as to render it at that time one of the most conspicuous objects in the garden, while its growth is so graceful that even when out of flower it is always pleasing. To enjoy this plant to the fullest extent, when first planted it should be trained to the wall until the required space is covered, and when that is done it should be allowed to grow freely without restraint. In this way it will push forth shoots in great profusion, and as they are nearly pendulous will completely hide the wall from view in summer, and in winter the slender shoots, often as much as 6 feet or 8 feet long, are, from their light brown cheerful-looking bark, far from unattractive, while the first few days of spring cause them to produce golden blossoms in abundance. *Cydonia* or *Pyrus japonica* is, where the walls are not high, a very suitable shrub to be trained thereon. It also flowers very early in the season, indeed at times nearly throughout the winter, and among its many varieties may be found various shades of colour ranging from bright crimson to white. The fruit is large bright green, and remains on the plant throughout the summer, but it is not edible.

PRUNUS TRILORA.—This, like many of its allies, is remarkably showy in early spring when laden with bright rose-coloured blossoms. It is more slender in growth than most of its class, and therefore more suitable for training on walls. Any one who has seen this *Prunus* trained on a wall at Kew when in flower cannot fail to be struck with its adaptability for that purpose. Some of the Brambles are very pretty, such as *Rubus deliciosus*, which is really handsome as a shrub, but well repays the shelter of a wall. It is a spineless species, with much branched stems, and leaves slightly three or five lobed. The flowers, which are white, are very showy, being often 2 inches in diameter, and borne in great profusion. In good soil this *Rubus* reaches a height of 8 feet or 10 feet. It is a native of the Rocky Mountains, where the fruit is said to be delicious, but with us it never ripens well. *Ribes speciosum* makes a good wall plant, and when so protected its Fuchsia-like blossoms are more freely produced than if treated as an

ordinary shrub. *Fremontia californica* succeeds best on a wall with a southern aspect, and in not too light and sandy a soil, but at the same time it must be thoroughly drained. Although it does not flower very freely, the foliage is ornamental, and when blossoms are produced, from their large size and bright yellow colour they form conspicuous objects.

THE POMEGRANATE withstands the winter perfectly around London when planted against a wall, and flowers freely so situated. There are now great numbers of varieties of this shrub both single and double, ranging in colour from red to white, while several bear striped or parti-coloured blossoms. All the pruning they need is thinning out some of the thin twiggy shoots when too much crowded. *Periploca graeca* is a curious, but ornamental climber, and one which flowers freely when on a sunny wall. The leaves are firm in texture, from 3 inches to 4 inches long, and ovate in shape; the flowers, owing to their colouring, have a very quaint appearance. They are produced on long-stalked clusters, and open about July. They are five-rayed, about 1 inch in diameter, and of a reddish brown colour thickly covered with short hairs. Besides the Honeysuckles already mentioned *Lonicera fragrantissima* must not be omitted. Its sweet-smelling blossoms are produced during the first months of the year, at a time when other Honeysuckles, except its near relative, *Standishi*, are dormant. It is best suited for low walls. The European Box Thorn (*Lycium europaeum*) is a somewhat common, but very handsome subject for covering walls, especially where rapid growth is required, as when established it grows freely, and soon covers a large space. Its small, pale, violet-coloured flowers are borne in great profusion, and as many of them are succeeded by comparatively large, bright scarlet fruit, this plant is well worth attention, especially as the long slender shoots are often as much as 6 feet in length, and studded throughout the greater part with berries. This *Lycium* should be treated as recommended for the Forsythia as regards training.

THE CLIMBING ROSES, or at all events most of them, are grand subjects for walls, and should on no account be omitted, as many of them keep up an almost continual succession of bloom throughout the summer, while others, such as the *Banksian*, if they can be induced to flower well, will then compensate for any trouble that may have been incurred.

One or two other things demand a few words, though for the sake of their foliage more than for that of their flowers. The Virginian Creeper, besides its rapid growth and ample foliage, is so brilliant in the autumn, as to fully account for its popularity. The smaller *Ampelopsis Veitchi* only needs a little support at first, when it will stick closely to the wall and grow freely when once established. The ample foliage of some of the vines well fits them for covering walls. Noteworthy kinds for that purpose are the cut-leaved and the purple vine, both varieties of the common Grape Vine. *Vitis cordata*, a large heart-shaped-leaved kind from North America, is also well worth attention, as is also *Vitis Sieboldi*, with moderate sized five-lobed leaves, bright green, very glossy above, and covered underneath with a white tomentum. *Vitis heterophylla humulifolia* bears bright blue berries really handsome, but to bring them to perfection a hot, sunny wall is necessary.

ALPHA.

Bedding Violas.—Whilst there does not seem to be so great a demand for these truly charming hardy flowers as once existed, it is satisfactory to find that raisers have not relaxed their efforts to produce improved varieties. Not a few of the kinds shown and certificated in the past, though charming for the moment, have failed to show endurance and hardiness such as are needed in a bedding Viola. I find *Yellow Boy*, one of the oldest, to be still the earliest and best of yellows. In old clumps it is beautiful, and in young plants the first to flower. *Mrs. Gray* is a pure white kind, one of the very earliest, and specially valuable with *Yellow Boy* for spring bedding. I am greatly

pleased with *Mrs. Turner*, a bluish violet-hued kind of the best form and stout. *Blue Lass* is an excellent blue, whilst the old *Cliveden Purple* and *Mulberry* make the best bedders in the maroon section. In the south, *Violas* to make a good show in the spring should always be planted out in October.—A. D.

VERBENAS FROM SEED.

THERE can be but one opinion respecting the future of the *Verbena*, and that is, it must be treated as an annual. No one perhaps regrets this more than I do, for time was when it was used largely for bedding, a purpose for which few plants are better adapted. I am old enough to remember the advent of that excellent variety, *Defiance*; as a scarlet-flowered *Verbena* for bedding it has not, either before or since, had an equal. At the time, however, of which I am writing there were many other varieties admirably adapted for bedding; but in the search for new kinds, such as *Mrs. Woodford*, *Emma*, *Woodwardiana*, and others of similar trailing habit, these have all been lost, and the garden in consequence has suffered, because the new introductions have altogether proved to be indifferent bedders. This is, however, no good reason why the *Verbena* should be banished from our gardens altogether, because for those who do not object to having a bed of mixed colours it is still available. For this purpose the plant must be raised from seed—a very simple matter.

THE FIRST STEP is to obtain seed that has been saved from flowers of good substance and various in colour. The earlier the seed is sown after this date, too, the better, and if when sown it can have the advantage of artificial heat, the plants will be larger, and consequently will flower earlier than if raised in a cooler temperature. Seed pans 6 inches deep, and from 12 inches to 16 inches over, are the best for sowing the seed in; these should be filled to within an inch of the rim with fine light sandy soil. After being well watered, the seed may be sown and thinly covered with light soil. To induce the seeds to grow quickly, there is no better place for the pans than a Cucumber or Melon frame in which there is a good bottom heat, and where they can be shaded until the young plants appear. When once the seedlings are up they grow quickly, and as they advance in growth more air and less heat are required. As soon as large enough the plants should be put singly into 3-inch pots, using no crocks, and fine sandy soil. They should then be replaced in a growing temperature until the middle of May, when they may be gradually hardened off and planted out in the beginning of June. Raising seedling *Verbenas* under cool treatment has not been altogether a success with me. I have sown them early in April in well-prepared soil in the open ground, but the plants flowered so late that they were comparatively worthless. I, however, found that a greater number of seeds will grow under cool treatment than when sown in heat. The proportion of the seeds which grow under the cool treatment was about three in five; but when sown in heat the proportion does not amount to more than one in five. This is, however, no new experience, for there are many other seeds that vegetate better when not subjected to artificial heat than they do with it. I have been more successful when I have sown seed in some deep boxes about the middle of March and then placed them in an ordinary greenhouse, when large enough planting them out in other boxes, or potting them singly in small pots. In this case the plants have commenced to flower fairly well in August, and have continued to do so until late in the autumn.

PLANTING.—I have found it best to delay the planting out until June, when the weather has not been favourable, and the result has been a stronger growth and an earlier show of flowers than if the young and tender plants had had to endure cold, rough weather in exposed flower beds. I am rather inclined to believe that of late years we have made our soil too rich for *Verbenas*; they

are excitable subjects, and when planted in rich soil they make rapid progress for a time, but suddenly come to a standstill when they have exhausted the soil near their roots, and this generally occurs when we get hot, dry weather in August. During my experience I have not found anything better as a dressing for *Verbena* beds than well-rotted leaves; 3 inches of these strewn on the surface, and lightly forked in, appear to suit them better than anything else. When we grew *Verbenas*, I always found that our plants became exhausted sooner, and were earlier attacked by mildew when we dressed the beds with animal manure than when we used leaf soil. J. C. C.

NAMES OF POPPIES.

MUCH confusion appears to me to exist about the nomenclature of Poppies. I remember thirty years ago a magnificent crimson variety which used to be called the *Crimson Oriental*. To my delight I discovered this some little time ago in an old-fashioned garden near this, and I rejoiced to see it exhibited last May at South Kensington (I think by Messrs. Barr & Sugden). I ventured to write to Mr. Wolley Dod (than whom, of course, there can be no higher authority) to ask him if he were familiar with this Poppy, and to beg him to tell me its proper name. He replied that it was *Papaver bracteatum*; that it used to flourish in a wonderful way with him when he lived at Eton, but not so well in his present locality, and he most kindly sent me two or three offsets, one of which I am in hopes will give me a flower in late summer. I saw seed of *P. bracteatum* advertised in Messrs. Carter's list; I got a paper of it, and have a good crop up, but it is evidently not the same Poppy; the leaf is quite different, and I feel inclined to doubt the seed of Mr. Wolley Dod's *bracteatum* being so procured as to be only a few pence per packet. Again, with respect to *Papaver umbrosum*, Mr. Wolley Dod tells me it is a yellow Poppy, and he added to his great kindness by sending a few seedlings of his variety. He will, I doubt not, be pleased to hear that three of these are now 16 inches across the plant, and are likely to bloom well. But in various seed lists, notably Carter's and Ware's, *umbrosum* is described as a crimson annual, much like the wild Corn Poppy, but larger. What am I to make of this contrariety? Perhaps Mr. Wolley Dod would kindly notice the matter in THE GARDEN, where, I doubt not, the subject would be interesting to many readers. DENIS KNOX.

Virginia Rectory, Ireland.

GOLD-LACED POLYANTHUSES.

THERE was a rare display of these at the recent *Auricula* Exhibition at South Kensington, more indeed than I have ever seen before; but it appears to be becoming certain that we must look to the northern growers for flowers characterised by those qualities upon which florists insist. The cool, moist climate of Lancashire, for instance, induces a more refined development than we are able to obtain about London, where it is difficult to grow them. Mr. Douglas appears to be the only southern grower who is at all successful with the gold-laced *Polyanthus*, but with all his skill he fails, as a cultivator, to impart to the flowers that refinement which Mr. Barlow and Mr. Brockbank does. The winter was very harmful to the *Polyanthus*. I hear general complaints of losses. Mr. W. Brockbank, of Didsbury, who has a large collection, says they died with him by the hundred; and I know that Mr. Barlow has also been unfortunate with his plants, and unhappily lost almost entirely several fine new varieties. I had a collection of some fifty plants, comprising such varieties as Cox's Prince Regent, George IV., Exile, Lancer, President, Cheshire Favourite, &c., that at Christmas looked most promising, but by the middle of February they were nearly all dead. All my care failed to prevent them rotting away near the collar of the plant.

There is such a demand for named varieties, that no doubt the plants are divided to an extent which

weakens them beyond endurance. It is, therefore, matter for sincere congratulation that Messrs. Barlow and Brockbank have succeeded in raising new varieties of a high character, and, as far as I have seen, of good constitution. Of Mr. Barlow's new flowers, Sunrise was the only one I noticed at South Kensington, and it was in excellent form, a perfect red in point of colour, with the lacing bright, even, and regular. It is a flower of great refinement, and it will be a matter for congratulation when Mr. Barlow is able to put this fine variety into commerce. Mr. Brockbank has evidently hit upon a fine strain of new varieties, two or three at least of which are of excellent promise and robust growth, so far as one could judge from appearances. Black Diamond is a fine and attractive black ground, the centre bright and clear, with a well-defined lacing to correspond. Nonpareil is also a black ground variety, perhaps scarcely so good in colour as the preceding, but with a clear, rich, bright golden centre and lacing, and good form. I think this may eventually prove the better of the two, but one cannot draw a correct conclusion from first sight. John of Gaunt, Lord Derby, and Excellent, likewise black grounds, were also shown by Mr. Brockbank, and if they are not strictly first rate, they will be very useful as parents.

Of older varieties shown on this occasion, the following were conspicuous: Lord Lincoln, Prince Regent, Lancer, Exile, George IV., and Cheshire Favourite, a very good half-dozen, but the first is very scarce and dear. R. DEAN.

WALLFLOWERS.

WHETHER we see them growing luxuriantly on the top of an old wall, or in the horder beds, or packed ruthlessly in bundles hawked for sale about the metropolitan streets, Wallflowers seem to possess a sweetness and a freshness of their own. It is customary to speak of them as old-fashioned flowers, but in this connection the epithet is one of endearment. In spite of the mania for new plants, and for new shades of old ones, florists do not neglect to provide us with these sweet-scented brown and golden blossoms, which come in the early spring to remind us that Nature has only been sleeping awhile. Rich and poor alike meet on common ground in their admiration of these old favourites. The cottage garden and the pretentious parterre are both bright with their blossoms. They hold their own against all rivals; and year by year the fashion, which pronounces Wallflowers to be favourites, recurs with the first days of spring. So hardy is the plant, that however hard the winter may be, it is seldom late in blooming. Long before the trees and bushes shoot we are cheered by its brightness. It is ubiquitous. In many a town garden, and in the tiny beds which lie close to the cottage porches in country villages, it is to be found. It blooms with unvarying luxuriance on ruined walls, whether desolate or in the midst of cities. In Paris it is bedded out in masses in the public parks. Even the ruins of old Rome are gladdened by its perfume. It can be found amidst all the fabled glories of Eastern gardens, and even there it is not despised. We have no means of tracing its antiquity in England, but it seems to be pretty well settled that it is not indigenous to English soil. At the same time it is found growing in strangely inaccessible places. It thrives in the crannies of the cliffs and in the clefts of craggy peaks. The old cliff at Dover is, for instance, a famous habitat of this hardy plant, and it must indeed possess a vigorous vitality, since it can survive the east winds there. The secret of the charm which the Wallflower possesses is perhaps to be found in its hardihood. Growing in the crevices of an old wall, it seems as though its roots were well content with such scanty sustenance as they can get from bricks and mortar; and, although it is sometimes cut off by very severe frosts, it generally endures the vicissitudes of our extraordinary climate with enviable indifference. The plant is largely cultivated by market gardeners, owing to the demand for cut blossoms; and the nurseries at Feltham

and Isleworth are famous as the principal source of the metropolitan supply. The Wallflower is, however, sweetest, and often finest, in the cottage garden, and it is reserved for a poet of the future to tell its story as the flower of the poor. It is, indeed, not a little remarkable that floriculture is helpless in attempting to change the popular taste in favour of new-fangled shades of colour. Of these many have been introduced, but the familiar hues which pass through every shade of gold to brown are still preferred to any of those which the gardener's art can produce. In the same way, the flowers which bloom in "the open" are more highly prized than the most gorgeous productions of the hothouse. The Wallflower is indeed "old fashioned," and perhaps that is the reason it is beloved. All through the winter cut flowers of it might have been seen in nearly every window, and even now branches of its rich brown blossoms are brought to our markets in thousands. —Queen.

Golden Moneywort.—The old green-leaved Moneywort is well known, but the variety having yellow foliage is not, I think, much grown. Unlike many variegated plants, it is of vigorous growth and forms a fine companion to the type, which for a window ledge in a north aspect is unrivalled, forming a dense curtain of verdure, which in its season is studded with bright yellow flowers. —BYFLEET.

Hoop-petticoat Daffodils.—Are not the flowers herewith sent remarkably fine specimens of *Narcissus Bulbocodium*? There is one which goes by the name of N. B. conspicuous; surely this must be the one. I have never seen such fine ones. They are from Jersey.—A. RAWSON. [They measured 1½ inches across the crown, and were otherwise proportionately large. The colour, too, a bright orange-yellow, seemed richer and deeper than usual.]

Eranthemum pulchellum.—Among winter flowering plants this old inhabitant of our houses well deserves a word in its favour; it is a plant of easy culture, flowers freely even in a small state, and the blossoms are of a beautiful rich bright hue. Notwithstanding the number of Eranthemums which we now have, I question whether any of them equals this. Small plants of it in 3-inch and 4-inch pots with but one good spike of flowers are very useful for decorative purposes, as the pots occupy but little space, and even if some of the plants get injured there will remain enough for stock for another season.—H. P.

Blue flowers—Gentiana verna.—"Delta's" note about the difficulty of cultivating this plant rather surprises me. I bought a small plant of it a year or two ago from Mr. Ware, of Tottenham, and it has flourished and flowered freely with me ever since. I counted fourteen blooms on it this morning—probably about two-fifths more than I had last year. I have it planted in perfectly common soil at the edge of a by no means well sheltered border, and close to it grows a very strong plant of *G. lutea* (which I am in great hopes to see flower this year) and a fine specimen of *G. cruciata* with some thirteen or fourteen flowering spikes. I am inclined to think that much of the difficulty found in cultivating Gentians, and, indeed, many other choice hardy plants consists in choosing the right time—the "psychological moment," as Prince Bismarck would call it—for planting them out. This certainly is not always to be found in the season which, *faut de mieux*, we are obliged to call spring, for the hateful, rasping north-east winds, which keep returning time after time, when one thinks they are finally got rid of, are simply death to unestablished alpine. I may add that the slugs (even my slugs!) never seem to look at *G. verna*, though they were so good as to eat several shoots of *G. asclepiadea* for me during the winter. By the way, if "Delta" wants another blue flower, let me suggest to him that lovely Borage-wort, *Mertensia* (*alias* *Pulmonaria*) *virginica*, and let me express a hope that in return he will not lend his authority, as an amateur gardener, to talking

about Aubrietias in connection with blue flowers. I am myself too old a bird to be any longer caught with blue chaff; but I well remember a few years ago rushing off in a hurry to see *A. croatica* which I saw described in a catalogue as "deep rich blue," and finding it, of course, a red-purple with a strong tendency to pink. Many people will probably agree with me that the difference between the blue of nurserymen's catalogues and the blue of fact needs settlement almost as urgently as the question as to "which is Daniel and which is the lion" among the white Daffodils.—J. C. L.

GARDEN FLORA.

PLATE CCCLXXXVII.

ROSE MARECHAL NIEL.

I REMEMBER the time when the beautiful, because truthful, picture which appears in this number of THE GARDEN would have created a great perturbation among those who love the Rose. Some would have denounced it as an imposition, and, resenting it as an insult, would have protested indignantly—"preposterous, absurd, impossible!" Some of less irascible temperament would have sighed, "How cruel to mock us with a vision of loveliness which can never be realised." Others more sanguine might have hoped "it may be a veritable fact. We have heard of Cloth of Gold, and we have grown Solfaterre. *To triumphe*. We have got a grand, hardy, yellow Rose at last, and we will have it if we pawn our boots."

Well, I can assure the younger brethren who have been brought up to it, and have always grown it as a matter of course, that it did make a grand sensation when it first came to us in all its golden glory. Never since we first smelt Devonians or cut our first Charles Lefebvre (about the size of the five-guinea cup which it helped us to win) had we been so thrilled, jubilant, inebriate. And though well-nigh twenty years have passed since M. Pradel saw the first bloom of it among his seedlings (I wonder whether he cried or danced, for without some such relief to his excitement he must have lost his reason there and then, and I should not be surprised to hear that he is crying or dancing still), it ever reminds, with each returning spring, of our first love, and charms us with almost all its pristine power.

No Rose, I think, brings so much satisfaction to the eyes and noses of Her Majesty's subjects, contributes so largely to the decoration of boudoir, bouquet, and button-hole as this magnificent *Maréchal Niel*. Wherever grown under glass, it is the first to cheer the ungenial days of March and April, and it is not only reliable and constant, never declining to open, like Dickens's fractious Periwinkle, always fulfilling in efflorescence the promise of its buds, but it is as ample and generous as it is sweet and fair. I have known several instances in which rosarians of limited means, or who resembled good Mrs. Gilpin in their economical habits, "for though on pleasure she was bent, she had a frugal mind," have paid the yearly amount of coal consumed in their greenhouse (cobbles, of course) with Roses cut from *Maréchal Niel*.

There must be glass to secure this early abundance, for this Marshal is no more frost-proof than were the marshals of Napoleon in that disastrous Russian campaign; and the Rose, on its own roots or budded so low on the Brier that it may make them in the soil surrounding, should be planted out (not kept in pots) and trained up wall, pillar, or rafter; or it may be grown like the Vine from an

outside border and brought into the house. However this may be, it should have an amplitude of fertile soil, and this should be continually enriched with manure, liquid and solid.

At the same time, though the *Maréchal* is not quite hardy, it may be successfully grown, with a little care, out of doors; and though I have once or twice been rebuked for my temerity, I have only failed for one season in producing its grand Roses on my walls. I believe the best plan to be this, to bring the upper growth from the walls and arrange it underneath, so that you may the more readily protect it from the frost. This may be done best with glazed frames, if you have them to spare, because they do not exclude the light, and are easily moved to and from the wall (in the latter position resting against stakes set some 2 feet from the wall), or, if these are not available, with garden mats. In April or May, according to the thermometer, the protective duties may be removed, and there may be free trade in wind and sunshine. The finest blooms I have ever seen have been grown upon walls having an eastward or southward aspect; and there is this further advantage for exhibitors, that they may with unobtrusive ingenuities, or by cutting a few days before the show, be enabled to include in their collection a Rose which is not only so beautiful in itself, but which educes by contrast the beauty of those around it.

When in its full vigour the *Maréchal* only requires the removal of thin and weakly shoots, but if the plant appears to be deteriorating close and low pruning must be tried. This Rose is somewhat capricious, and liable to sudden and mysterious decay, so that it is best to have a young plant coming on and to keep up a sure succession.

As to Roses generally, I have a good hope that, though much injury has been done, "there's life in the old dog (Rose) yet," and I see strong signs already of its recuperative power. Should we have the phenomenon of that genial May, which "never is, but always to be," we may have a happy Rose-tide after all. As with other weakly invalids, they will require good support in their convalescence; and as I am not a member of the Blue Ribbon brigade, I propose to administer a gentle stimulant.

Of novelties, I only know that *Merveille de Lyon* promises to be a marvel and a lion also—a white lion, "larger, fuller than the *Baroness*, 4 inches in diameter." What can mortals wish for more? The raiser says that it is undoubtedly the finest Rose ever sent out; and who knows its qualities so well as he? "Do yer think," said one rustic to another, who was somewhat incredulous at a fair, "that the gentleman 'ud say as the giant wor ten foot high if he wor'n't ten foot high—spooney?" S. R. H.

Deformed Roses.—I send you malformed blooms of *Boule de Neige* Rose for inspection. They are taken from a large plant growing in a house constructed by Rendle. Fully one-third of the blooms come like the enclosed, full of centre buds and entirely useless.—W. W., *Brough*. [Your Roses, after they had formed flower-buds, have begun to grow afresh, owing to some exciting cause, such as a sudden rise of temperature or excessive stimulation at the root.]

Malformed Rose (*G. W. E.*).—A by no means uncommon malformation, and one which shows the close relationship that exists between flower buds and wood-buds in certain stages of growth.

ROSE GARDEN.

PROPAGATING ROSES.

AT no time during the whole year do Roses strike more readily from cuttings than at present. Plants just out of flower that have been gently forced will furnish cuttings, and the sooner they are taken off after the flowers are faded the better, because longer time will be given them to grow into plants. Anyone with a common hotbed or other convenience for affording a gentle bottom heat in a close structure will have no difficulty in finding suitable quarters for the cuttings. Assuming that there is this convenience, the first step should be to prepare a sufficient number of 3-inch pots; these should be first drained and then filled with a fine sandy soil. Ordinary potting soil will do if sandy; but if a mixture has to be prepared, it should consist of three parts loam and one of sand sifted through a fine-meshed sieve. When the pots are ready the cuttings may be taken; each should have three or four joints, and in every case it is desirable to leave two fully developed leaves on each cutting. One cutting placed in the middle of each pot with the name attached to it is sufficient, and after being well watered the pots must be taken without any unnecessary delay to the frame or propagating pit, as the case may be. Here careful attention is necessary to produce satisfactory results. A moist atmosphere, with a bottom heat ranging from 75° to 95°, and with only just enough air admitted to prevent any excess of accumulated moisture in the frame, is the sort of treatment which they require, and partial darkness for the first eight or ten days is a necessary condition. In short, the cuttings should be shaded from 9 a.m. to 6 p.m. for the first ten days in order to maintain the requisite degree of moisture about them. Water should be given as often as may be necessary, and on the evening of bright days both cuttings and the sides of the frame should be gently syringed, the object being to keep the foliage from withering. If the leaves can be kept fresh and green for the first fortnight, there need not be much fear of losing the cuttings. With careful management, quite 85 per cent. of them will form roots in a month, and they will also have commenced to make growth, a sure sign that the roots are active, and measures should be taken to carefully harden the growth by admitting more air and reducing the supply of atmospheric moisture. If the progress has been satisfactory from the first, the plants should be ready for shifting into larger pots in six or seven weeks. The advantage of putting each cutting separately in a single pot will then be apparent, as they can be potted onwards without any serious disturbance of the roots. To induce a vigorous growth it is necessary that the plants should have a

RICH HOLDING SOIL. The most suitable for them should consist of three parts good fibrous loam and one part rotten hotbed or farmyard manure, with a sprinkling of coarse sand or road grit; all should be well mixed together and passed through a coarse-meshed sieve, but care should be taken that the mixture is not wet when used; if it is, it will be sure to run together in a compact mass, into which the roots will refuse to penetrate; indeed, unless the soil is in a suitable condition as regards dryness, it should be spread out on the floor of an open shed for a few days to allow some of the moisture to escape. These details may appear somewhat tedious, but they are necessary if early and satisfactory results are to be expected.

IN POTTING provide rather liberal drainage and use only clean pots. From the cutting pots shift into a 6-inch size pot, press the soil moderately firm, and give the roots a gentle watering at once. When potted replace the plants in a close pit or frame, and if they can be set on a slight bottom heat so much the better, but this is not absolutely necessary so long as they can have a position where currents of air do not reach them, and where they can be shaded during strong sunshine. For the first fortnight very little air will suffice; after that time they will require much less shade and more air, but they ought not to be fully ex-

posed all the summer if it is desired to get them well established before winter sets in. The shelter of a cold pit or frame is all they require. Under such treatment they will become well rooted and vigorous. They should be allowed to remain in the cold pit all winter or in some other light structure secure from frost, and in spring they will produce a few good flowers before any Roses can be had from the open beds. If required for pot culture, they should be shifted into 8 inch pots as soon as they go out of flower, and then placed in a cold frame for a few weeks to get established before being exposed to the open air. No further shifting into larger pots will be required, *i.e.*, if intended for planting in the open ground; but Rose trees that have been wintered under glass ought not, even in the most favoured localities, be planted out until the middle of May, and in the northern counties the first week in June is quite early enough. J. C. C.

Gloire de Dijon Rose.—This grand old Rose is unquestionably one of the best, if not the very best, that can be grown, either indoors or out. In the latter position it is exceedingly hardy, and almost the first in bloom and the last out; while under glass it is very rare that it is entirely without flowers, and for many months during early spring and summer it comes exceedingly full. We have one in a house now that has a stem as thick as one's arm, from which we can any day cut great numbers of Roses and half-opened buds, all having stout sturdy stems, that keep them erect and show them off to advantage. The plant referred to is budded on a climbing *Devoniensis*, a capital stock for any of the strong rambling sorts, and would, I should think, be the very best stock for *Maréchal Niel*, of which so many complain, owing to the way which it has of cankering or going off at the union between stock and scion. This appears to be brought about by the swelling that occurs there. None of the stocks that I have seen it on yet appear free enough for it. The way in which we manage our *Gloire de Dijon* is, when the first flush of bloom is over, to prune it in, or rather thin it out severely, and when it breaks again, which it quickly does, we lay in the best of the young wood loosely and let it run as long as it will. It is from the buds on these shoots that it flowers the following year, and few, if any, miss showing blooms. As a standard or bush in a bed *Gloire de Dijon* is comparatively useless, but allowed to grow unrestricted on a wall, trellis, or fence, as its nature requires, it will furnish Roses in abundance. To have flowers at different seasons it is a good plan to have plants in various aspects; those on a south aspect are in bloom very early, while others in more shady and cool situations succeed them, and afford blossoms quite unique in colour and laden with the sweetest perfume. Some we cut from a north-east wall last year were superb in both these respects; they were of the richest fawn colour and full of odour, of which *Gloire de Dijon* has as much as any other Rose, and perhaps more.—S. D.

Out-door Hyacinths.—In response to Mr. Cornhill I will shortly state my treatment of these flowers. In November the ground is well worked to the depth of 16 inches; the upper half of the earth is then thrown on one side, and about 4 inches of good compost, generally from an old Melon bed, takes its place; upon this the bulbs are placed, and the ground levelled up with the soil previously removed. The small bulbs are planted in a nursery till they are large enough to go with the others. After flowering the seed vessels are cut off, and I always find it better to take up the bulbs before the leaves are quite withered, lest they should either decay or push prematurely. They are now dried for a few days in the open air, and laid not more than three or four deep in hamper, and thus they remain in any cool, dry place till November comes again. When they have been forced in pots, after flowering they should be plunged into the soil in their pots, and, as Mr. Cornhill suggests, not be allowed to die down till their natural time. These bulbs

will not recover the first year.—T. H. ARCHER-HIND, *South Devon*.

SEASONABLE WORK.

INDOOR PLANTS.

BORONIA ELATIOR.—This is such a profuse-flowering subject and so easily managed, as to make it deserving of general use wherever a greenhouse or conservatory exists. It will last in flower for over two months, and from its graceful habit of growth it is a pretty object even when not in bloom. As soon as the plants have done flowering they should be slightly cut over, shortening the last season's shoots about one-third their length; if this is done the plants will keep for years without getting straggling or too large for ordinary purposes.

HYDRANGEAS.—A sufficient stock of cuttings of these should, if not already put in, be seen to once, using the young shoots, which the spring-flowering plants usually produce freely. If the cuttings are kept moist, close, and in a little heat, they will root in a fortnight. More plants intended to bloom should be pushed along to precede those that have been retarded, giving them plenty of manure water as growth progresses. Quick-growing, gross-feeding plants such as these are only seen in their best condition when liberally supplied with nutriment. Dip them in Tobacco water or fumigate as soon as aphides appear.

LILIES.—As the shoots of these extend, keep the pots well up to the glass; for the summer and autumn-flowering kinds a cold frame in a light position, with the lights off in the daytime, will favour stout, sturdy stems much more than if kept in a plant house. If the stems are at all drawn up quickly the lower leaves will be proportionately thin in texture, rendering it impossible to keep them on until the plants bloom. As the earliest will now be growing freely, supply them regularly with manure water, so as to get them strong, as on this to a great extent depends the quantity of flowers which they produce. It is the nature of some Lilies to form a quantity of roots from the lower joints of the stem above the bulb; means should be taken to preserve and encourage these by adding soil, so as to cover them, or by potting them lower in pots a size larger; these stem-roots may not assist the growth of the bulbs, but they have a marked influence on the flowering.

CHRYSANTHEMUMS.—Late-struck cuttings should at once be placed in 5-inch or 6-inch pots, and treated so as to get them on, stopping the shoots of those that are intended to be grown bush fashion. Do all that is possible to keep them sturdy; if they are at all drawn up in their earliest stages it is useless to expect the lower leaves to stand until blooming time. To this cause quite as much as to inattention in the way of giving with water through the summer is attributable the naked condition these plants get into before flowering.

ACHIMENES, GLOXINIAS, AND GESNERAS.—Achimenes started some time back should not be allowed to make too much growth before they are transferred to the pots or baskets in which they are to bloom. It is well not to overcrowd them; if this is done, their flowering will be comparatively short-lived, and the leaves will be almost certain to have a sickly yellow colour. Few summer-blooming plants are so bright and effective as these when well managed; where it is desirable to have them in bloom over as long a season as possible, they ought to be started into growth in succession, or else a portion should be subjected to less warmth than the rest, but they are heat-requiring subjects, and will not do well if deprived of a sufficiency of warmth during the early stages of their growth. Gloxinias that were started early will now be pushing up their flowers, and need all the light that can be given them so as to keep the foliage stout and give strength and substance to the flowers and the stalks on which they are borne. The flabby, weak, half-prostrate condition in which these plants are often found

destroys the character of both the foliage and flowers. The solid tubered species and varieties of Gesnera, such as *G. Cooperi* and others, are beautiful and most useful summer-flowering plants, not nearly so generally grown now as they deserve to be. They succeed with moderate stove heat, and occupy comparatively little room; and where sufficient quantities of them are grown a succession can be kept up. *G. Cooperi* will flower twice in the course of the season if well treated, the second crop of shoots yielding a head of bloom little inferior to the first. The variegated section is handsome both in leaf and flower, but unless means are taken to keep them free from such pests as mealy bug and thrips, their leaves soon lose their beauty, the means that have to be employed to rid them of the insects destroying their velvety, lustrous appearance.

CAMELLIAS AND SPARMANNIA.—Camellias that flowered earliest will now be in active growth, and if at all deficient in vigour through want of root room, soot water should be given once a week; this will speedily show its effects in the increased size and deep colour of the leaves. *Sparmannia africana* is another plant easily grown, and one of the freest of free bloomers. Its white flowers, set off with quantities of singular filaments, have a distinct appearance unlike anything else, and, being produced during a considerable part of the winter and spring, render the plant doubly useful. To secure large specimens of it, cuttings ought to be struck in the usual way in a moderate heat about the beginning of March, and grown on with plenty of room, as required in summer. For such plants 12-inch pots will not be too large in which to bloom, but cuttings put in now will make good flowering examples in 8-inch or 9-inch pots. Ordinary sandy loam will suit them, and they like plenty of light, the foliage standing more sun under glass than that of most things.

FORCED SHRUBS AND BULBS.—As has before been pointed out, the too common practice of allowing shrubs, such as *Andromedas*, *Lilacs*, double-flowering *Plums*, *Ghent Azaleas*, *Laurustinus*, and *Rhododendrons*, after having been forced to remain comparatively uncared for is wasteful. Although such plants usually require a second season to bring them up to the condition they were in previous to forcing, it is well to recollect that in most cases the warmth to which they have been subjected has caused them to make a quantity of young growths in addition to their roots also being set in motion, and unless they are gradually inured to the open air before being turned out of their pots, they suffer so much as to be reduced to all but a state of worthlessness; whereas, if duly cared for, with, after blooming, a year's rest, they will again do good service. The course of treatment they have undergone tends to check all inclination to exuberant growth, in place of which a disposition to flower profusely is secured. If the latest bulbs, such as *Hyacinths*, *Narcissi*, *Tulips*, *Crocuses*, and *Scillas*, which will have bloomed without much forcing, are similarly well cared for by being turned out in the reserve ground and sufficient water given, they may be made useful in different ways, as all but the *Hyacinths* will, after an interval of a year, bloom in the open ground as well as if they had never been subjected to pot culture.

FLOWER GARDEN.

SUB-TROPICAL GARDEN.—The beds may now be edged and raked down ready for planting, but previous to doing this give such beds as are to be filled with plants that require abundance of manure a good scattering of guano or other fertiliser, which will thus get covered with soil at once. A commencement may then be made to plant out the hardier kinds, such as ornamental shrubs, *Australian Dracenas*, *Eucalypti*, *Hempes*, *Punkias*, *Fish-bone Thistles* and also the hardier edging and groundwork plants, such as *Cerastiums*, *Ajugas*, *Sedums*, *Veronicas*, and *Harrison's Musk*; the last is a fine groundwork plant for large growing dark-leaved plants in the way of *Gibson's Ricinus*

and *Canna Van Houttei*, and the partial shade which these afford seem to be just what is needed to keep the Musk in continuous flower from early in summer until late in autumn. The tender section of plants will still need attention indoors; it will not be safe to plant them out till quite the end of the month, and some of them not till June. They should not be allowed to get root-bound, but be grown on freely, being given plenty of space and air. A single plant well grown affords more real satisfaction, and does as good service when planted out as do a dozen that have been huddled together in heat. Tobacco, Chilian Beet, *Lovelies*-bleeding, and *Perilla* do best when planted in a very young state; they will now be ready to prick out into boxes, which when filled place in frames, and keep them rather close till the roots have begun to work in the new soil, then give air freely, and plant out in the last week in this month.

MIXED BORDERS.—These must now be furnished for the summer. Asters, Stocks, Marigolds, Larkspurs, Zinnias, and indeed all kinds of annuals may be utilised for filling up vacancies. They should be planted in clumps containing five or seven plants each, taking pains to have the taller growers at the back part of the border; not that uniformity of height in such a border is desirable—far otherwise, but simply that the arrangements may not look too lop-sided, owing to the tallest plants being too much in juxtaposition with the shortest. The common kinds of plants may still be sown for late flowering, viz., *Delphiniums*, *Pyrethrums*, and *Dielytras*. Tall *Veronicas* will now need tying up, in doing which endeavour to avoid a bunched-up, broom-like appearance. On the contrary, tie them as loosely as is compatible with their freedom from injury by wind or heavy rains. If continued gaiety of the borders be desired, and time can be devoted to the matter, many of the earliest kinds of spring flowers, such as *Primroses*, *Daisies*, and *Arabis*, that have now done flowering, may be taken up and planted in the reserve garden, and their places filled with any of the annuals mentioned above, or with ordinary kinds of bedding plants, such as *Pelargoniums*, *Calceolarias*, *Petunias*, and *Verbenas*; single and double *Dahlias*, *Hollyhocks*, *Marvel of Peru*, and any spare *Cannas* and *Castor-oils* that there may be will look well at the back part of the borders.

GENERAL WORK.—Weeding and, after rain, rolling walks and mowing with the scythe for the first time lawns formed last season. These will now need attention. Get vacant beds in readiness for the reception of bedding plants. Transplant spring flowers and bulbs to the reserve garden, and at the same time increase the stock of desirable kinds by division and offsets. Clear *Roses* of greenfly by syringing the plants with soap-suds, and in bad cases with Tobacco water. Tie up climbing *Roses*, and direct the growth of recently-planted climbers, such as *Ivy*, &c., by tacking in the principal shoots.

ORCHIDS.

EAST INDIA HOUSE.—Sufficient instructions have lately been given as to shading this house and the best positions for the different sections of Orchids. It may, however, be well to again allude to the *Angracums*. They require a warm, shady position, and a constant watch must be kept for thrips; they get into the axils of the leaves, and are often not seen until traces of their work are observed on the leaves. It is a good plan to have a small vessel filled with diluted Tobacco water placed in the house, and a small camel's-hair brush at hand with which to apply it to the leaves whenever traces of the insect are to be seen. If it is possible to fumigate the house, that may be done on successive evenings; it will kill both thrips and aphides. In our case there are plants in the house that will not stand Tobacco smoke strong enough to kill thrips, and therefore we must be content to dip or wash them. Plants of *Odontoglossum Roezli* in this house have been much infested with thrips. They ought now to be clean, for the flowers just opening will be injured

by dipping; even flower-buds are injured by the operation, and do not open well. We also grow our *Calanthes* in this house, although one 5° lower would probably be better. The evergreen section, such as *C. veratrifolia*, *Masuca*, and *Dominii*, were surface dressed with good loam and rotten manure nearly two months ago, and thick, healthy white roots are now running up into the loam. If not already surface dressed, that operation may yet be performed, and as the flower-spikes are well advanced (indeed, in some cases the flowers are open), it is necessary to watch them in order to destroy any of the yellow aphids, which sadly mars the beauty of the pure white blossoms. We remove the pest with a camel's-hair brush, but it ought to be destroyed by dipping in some solution before the spikes are seen above the foliage. The temperature of this house should not fall below 65° at night, and often it will be 70° at 10 p.m., falling perhaps a few degrees before morning.

CATTLEYA HOUSE.—Some grow *Cattleyas* with scarcely any shade at all; but we are still of opinion that the safest way in which to grow *Orchids* of any kind is to shade them from the sun, but we would let them have as much light as possible. *Cattleyas*, such as *C. Mossiae*, *Warneri*, *Mendelli*, &c., are pushing rapidly into bloom, and ought to be in a light position near the glass, so that when the flowers open they may be good in substance and colour. The only way by which *C. gigas* may be flowered satisfactorily is to suspend it near the glass in baskets. Large specimens ought to be raised in pots, so that the tops of the leaves may not be more than a foot from the glass. *Odontoglossum Phalenopsis* should now be in flower. This is a very desirable species, and one which lasts long in perfection, but it seldom does well unless suspended near the glass. It requires to be dipped frequently in weak Tobacco liquor to destroy red spider, which attacks it, and often does much mischief before it is observed. The *Anguloas* are now coming fast into flower, and as roots are being formed at the same time, they also require considerable supplies of water. See that no yellow aphides are lurking in the wrinkles of the leaves. As large importations have recently been made of *Dendrobium Wardianum* and *crassinode*, those who have plants requiring to be potted should use small shallow pans. They are light and can easily be suspended from the roof; as soon as roots are emitted from the base of the new growths, watch for slugs and give water freely.

COOL HOUSE.—With hardly any artificial heat the thermometer seldom falls in this house below 55° at night, unless perhaps an hour or two before daybreak, when the thermometer is low outside; under these circumstances it is desirable to remove any cool house plants that have been wintered in the *Cattleya* house to their summer quarters in the cool house. Such *Masdevallias* as *M. tovarensis* and all those of the *Chimeroid* section, also *M. Wageneri*, &c., would now do better in the cool house. Indeed, our plants of *M. tovarensis* were removed long ago, as we found, by trying half of them in the cool house and the other half in the *Cattleya* house, that they did best where they were coolest. It may be, if the winter was more severe, that they would succeed best in warmer quarters. Numbers of plants of the *M. Chimera* section of *Masdevallias* have been recently imported, and all of them, except the true *Chimera*, which produces its flowers from an upright stem, should be potted in baskets, the flowers being produced from the base of the plants, the flower-stems having a downward tendency. They like a position near the glass, but require a moist atmosphere, and, like the rest of the *Masdevallias*, plenty of water at the roots. The cool house is now gay with flowers of *Odontoglossums*, and the earliest-flowering *Masdevallias*, such as *M. Veitchii* and *M. Chelsoni*, are in flower, and form a striking contrast to the wealth of white, blush, and variously spotted forms of *Odontoglossum cirrhosum*, *Pescatorei*, and *Alexandre*. While there are so many plants in flower we are anxious to keep them in good

condition as long as we can, and are careful not to sprinkle too much water about at night. The flowers do not damp off so much when there is a little heat in the hot-water pipes as they do when these are quite cool. A circulation of air night and day promotes the health of the plants and tends to the better preservation of the flowers.

FRUIT.

CHERRIES AND PLUMS.—Examine the trees and fumigate if necessary before the fruit changes colour. Green fly may easily be eradicated, but the black and brown aphids often give a great deal of trouble, and it is not always convenient to cut off and burn the points of the shoots; but if taken in time, regular dipping in tobacco water will soon clear the trees. As the ripening period approaches, see that the roots are in nice condition and properly mulched to keep in moisture. Go over the trees and stop all superfluous shoots at the fourth leaf, tie in leaders, discontinue syringing, and protect from birds by hanging fishing nets over the ventilators. If trees in pots are too thickly set they may now be thinned. Feed well and mulch to keep the surface moisture in the pots and to prevent the constant use of water. Syringe Plums twice a day with soft water until the fruit begins to ripen, thin well when stoned, and feed with liquid at every watering. Plums will stand more heat than is good for Cherries, but nothing is gained by its application. Fumigate for fly. Keep the trees pinched and tied in, and see that *Golden Drop* and other late kinds intended to hang are not distressed by overcropping.

MELONS.—Where the pot system is followed the first batch of plants will soon be ripening off their crop of fruit, and, time being an object, see that another set is thoroughly established in fruiting pots ready to take their place. Although cleansing after the first crop is not absolutely necessary, cleanliness is an important item in good culture, and always pays for the small outlay in quicklime and sulphur. When the fruit in succession houses has attained the size of ducks' eggs select the fittest for swelling away evenly together, cut off duplicates and all lateral growths, top-dress with heavy loam, bone dust, and dry cow manure, and feed liberally. Avoid wetting the foliage at the morning syringing, but damp all paths, walls, and surfaces; ventilate freely until noon, and syringe overhead after closing for the day. Pay particular attention to plants in pits and frames, and carefully avoid producing a check by stopping or cutting during the time the fruit is setting. Fertilise all female blossoms, and at the same time draw them up above the foliage to the influence of solar heat and light. When a good set has been secured, pinch two joints beyond the fruit, elevate those intended for the crop on inverted flower-pots, and trim away all surplus growths. If the bed of soil has been made between two planks placed 2 feet apart, the advantage of the plan will now be discovered in the facilities offered for top-dressing, ramming, and feeding. Melons in pits and frames should never be shaded, neither should the soil at the outset be enriched with manure, but food of the richest quality may be given to them during the time they are swelling their fruit.

HARDY FRUIT.—Seldom perhaps have fruit trees of all kinds broken away in a more satisfactory way than they have done this spring; but Plums and early Pears on pyramids and bushes have been much injured. Currants, too, have suffered, but Gooseberries, where protected by their leaves, seem to have escaped, and trees on walls are mostly safe. Disbudding will soon require attention, but, considering that we are not long out of April, the little-and-often system of taking off a few shoots at a time should be strictly adhered to; and although the trees may be the better for having the covering removed, it should be kept within easy reach, and temporary copings should remain on the walls for some time longer. Give regular attention to the thinning of Apricots, which are a tolerably good crop, and wage incessant war with the active grubs, which soon do serious

mischief, particularly where the trees are heavily cropped and there is a dearth of foliage. Wash the trees well with clean water when days are mild and cloudy. Mulch the borders with good rotten manure and old lime rubble, as calcareous matter will be in great demand at stoning time, and water copiously to insure its reaching every part of the soil in which the roots are embedded. Take the foreright growths off Peaches, also the small fruit from the shoots. Wash well with clean water, and always have the usual insecticide ready for application to parts affected on the first appearance of green fly. Examine the borders and see that the recently root-pruned or old trees do not suffer from the want of good mulching and feeding. The usual mode of training a Peach tree against a south wall or within a few inches of a glass roof, so as to expose every leaf to the sun, is a most trying position, and unless a liberal supply of water is given to the roots and foliage, insect life will soon be abundant, and heavily cropped trees will ripen their fruit prematurely if they do not cast it when stoning. Look over Cherries and Plums on walls, destroy the grub by pinching the points of the shoots, and dip or syringe with Tobacco water on the first appearance of black or brown fly. The latter soon paralyses the young growths, and the grub makes very short work of a crop of Cherries; hence the importance of thoroughly cleansing the trees and walls when the trees are unnailed in winter. Maiden Strawberry plants from which the current year's supply of runners is to be obtained may be divested of their flowers, well mulched and watered if necessary, and autumn-planted beds may be made very firm by treading when the ground is dry. If fresh stable litter is plentiful and at hand all the fruiting beds will be the better for a good covering after rain and before the flowers and foliage get too forward. In due time the rain will carry the ammonia down to the roots; sun and wind will bleach the litter and render it equal to new wheat straw long before the fruit is ripe.

CUCUMBERS.—When the Cucumber house is divided into several compartments, sections in which the plants have been longest in bearing should be cleared in regular succession to make room for young plants which come into bearing in a very short time, and the necessity for constant fire-heat having ceased, a clean, healthy growth will be secured throughout the summer. It will be necessary to clear away all old soil and plunging material prior to scalding, cleansing, and washing with quicklime, otherwise the usual pests—spider, woodlice, and worms—will soon re-establish themselves. Make the hills or ridges for summer use as far as possible from the top-heat pipes, and endeavour to secure a steady, lasting bottom-heat from fermenting materials in preference to having constant recourse to firing, for much as the Cucumber can and does often yield good crops for a time under high pressure, all practical growers are agreed that a top-heat ranging from 70° to 85°, with air when draughts can be avoided, and a bottom-heat of from 80° to 90° will keep them vigorous and fruitful as long as daily details are properly attended to. If old plants cannot be dispensed with, cut them over and ply the syringe well, using water at the temperature of the house at the time of closing. Shade for a few days, and let the heat on fine afternoons run up to 90° to economise night firing. Avoid the use of solid manure for the roots, but feed well with tepid liquid and earth with rough fibry loam, from which the fine particles have been separated, and a liberal mixture of old lime rubble, which will absorb and give off moisture when most needed by the foliage. Spring-sown plants in pits and frames will now be in bearing and in some danger of being over-cropped. Dress over as often as the weather will permit, peg out the young Vines, and carefully guard against getting the foliage too gross by constant stewing in a vapour atmosphere, but keep it stout and healthy by giving a little back or front air, according to the direction of the wind, on fine mornings. Shut up about 3 p.m. with a flush of sunheat and moisture, and let it gradually

descend to 70° for the night. If all the heat is obtained from fermenting materials, renovate back and front linings alternately. Cover well with dry mats, and provide for the escape of noxious gases by giving a chink of air after covering up for the night.

MARKET FRUIT GARDEN.

WHERE the ground has been roughly dug during winter, as is the custom in Kent, many strong rooting weeds will now be pushing up strongly, even though they have been buried for months. Coltsfoot, Docks, Couch Grass, &c., will find their way to the surface if only buried one spit deep, and experience proves that in stiff soil, unless spring and summer cultivation are strictly carried out, the land soon gets into a foul condition, as in autumn, owing to the press of work connected with harvesting the fruit, the weeds generally make rapid headway, more especially if the season be wet. At the winter cultivation it is therefore difficult to clean the ground properly. It is dug as roughly then as possible, so that the frost may act on the lumps of soil and pulverise them. Now, therefore, is the time when workmen, armed with stout three-pronged hoes like little forks set on a handle like a rake, proceed to pull over the lumps just named, and work them down to a fine tilth, bringing as the work proceeds the large weeds to the surface, when in their blanched state they quickly wither up. When quite dry they are collected and put in heaps to burn; this thorough stirring destroys all the seedling surface weeds and renders the work of destroying succeeding crops a light matter, as with a well pulverised surface hoeing with draw hoes is performed at a trifling cost per acre, and when the bushes or trees are wide enough apart, the horse hoe and harrow are used instead of manual labour.

GOOSEBERRY CATERPILLAR.—A sharp look out must now be kept for Gooseberry caterpillars, for if allowed to get established, they not only spoil the crop, but the bushes as well. In this locality acres of bushes divested of foliage last year are looking very weakly and are bearing very light crops, while those carefully cleared of caterpillars are heavily cropped. There are many remedies for this pest and many ways of applying them, but the general plan is to dust powdered hellebore on the bushes when the first signs of caterpillar appear. The hellebore kills all it touches, and if followed up a few times, will usually keep the bushes quite clean. Tin canisters with holes made in them, like flour-dredgers, are employed for dusting the trees, and as the caterpillars usually start from the centre, and clear the leaves off the tips of the shoots, it is necessary to lift up the outer branches and carefully inspect the centre of the bushes, for they multiply so rapidly, that if allowed to remain many days undisturbed, their destruction is almost hopeless.

GRAFTED TREES.—All kinds of grafted trees will now need frequent inspection, as the occasional showers we are now experiencing will loosen the clay coverings, and if not replaced quickly, the drying intervals between the showers act most injuriously on the graft, and that, too, at the most critical stage of its existence. Any coverings that have given way must therefore be replaced at once, and those that are cracked must have some fresh clay worked into the fissures, as the more thoroughly air is excluded, the more certain will be the success of the grafts.

RECENTLY PLANTED TREES must be kept firmly staked and tied to prevent wind-waving, for as the leaf gets heavy, the strain will be even greater than it now is. See that they do not get chafed; put plenty of soft material round the stems before tying, as unless the top is kept steady, the young freshly formed rootlets get broken, and the tree thereby considerably checked. Look to top-dressings; see that they are not only ample, but also frequently stirred. In the case of old orchards on Grass, this is a good time to remove Nettles, by forking them up by the root, also Docks, Thistles, and other coarse-growing weeds.

Keep an extra supply of sheep grazing under the trees now, as in addition to the abundance of Grass there is usually greengarden crops that can be spread in orchards to supplement their food. All kinds of the Brassica tribe, such as Cabbage stalks, winter greens, &c., when running to seed are far better put into the orchard for the sheep than on the rubbish heap, as the little they leave of the hard stalks can be raked up and burned when dry. The season for gathering fruits will soon set in. About here vast quantities of Gooseberries are picked green, and those who get them forward enough for the Whitsuntide market usually get a high price for them. See to the stock of baskets, packing paper, labels, sticks, &c., so that when required, no delays may arise. Many of these can be prepared on wet days when outdoor labour is at a standstill, and the profits of fruit growing demand that economy of time as well as of other resources be practised if the cultivator would live by his labour.

KITCHEN GARDEN.

HERBS.—Sweet Basil should be sown in a frame under glass, and for a very early supply in pots in heat. When fully grown and just showing flower it should be dried, powdered, and kept in bottles corked up tightly; in fact, all herbs retain their flavour when kept in this manner. Mint should now be planted, both the Spearmint and Peppermint. The usual system pursued is to lay in three roots in a shallow drill, but the better plan is to take cuttings of them, *i.e.*, the shoots that come away from the old roots with a small piece of white stem, and which are sure to grow if bedded in nice light land. Concerning Sage, the old proverb, "Plant Sage in May, it is sure to pay," is literally true; slip the side shoots from the parted plant, and plant them with a dibber. This herb makes a good edging plant where trim Box edging cannot be had. Borage needs but little attention; where once grown scores of seedlings make their appearance, and supply all our wants gratis. Perhaps the most useful of all herbs is the knotted Marjoram; this should be sown under glass, and planted out in small tufts the latter end of May. Tarragon is a useful herb, but in many places does not do well. Here it grows fine and strong. We part the old plants yearly, and replant them in a different place, giving them a few barrow-loads of burnt refuse. Such herbs as Savory, Thyme, Marigold, and all the more common varieties do well sown outside the second week in May. Lavender we strike from cuttings under hand-lights, and also Rosemary; both are very useful. Lastly, our good friend Parsley must not on any account be neglected.

TOMATO plants ought now be 1 ft. high, and should worthily occupy 6-in. pots by say the 15th of May. They will be showing flower, and when planted by the side of south walls, will begin fruiting at once. President Grant Tomatoes and similar monstrosities are not what is wanted, either for exhibition or private use. Tomatoes should not be large; on the contrary, about six to a pound is about the right size. Speaking of Tomatoes, we may add that the green fruits gathered in autumn, and laid on shelves under the glass to ripen, certainly become red, but as regards flavour it can only be compared with that of box fruit from our neighbours across the Channel. English Tomatoes fetch from 2s. to 2s. 6d. per lb., while French ones only realise from 1s. to 1s. 6d. Hoe between all growing crops whenever the weather is suitable. Plant double rows of Lettuces on the top of Celery ridges. Keep a sufficient quantity tied up in the winter quarters to meet all demands. Sow successional crops of Turnips, Lettuces, Radishes, Mustard and Cress, &c. Now is a good time to thoroughly clean walks, cut Box edgings, and finish by putting a little gravel on the walks, so that all may be smart and trim for the summer.

The Garden.—General Index to the first twenty vols. now ready, strongly bound, price 12s. 6d.

KITCHEN GARDEN.

HARICOT BEAN CULTURE AND COOKERY.

MRS. RAMSBOTHAM, as quoted by *Punch*, says that "hashed mutton and varicose Beans when in season is an excellent dish," and in my opinion she is quite correct in her estimate of the dish, although, as usual, incorrect in her orthography. It is surprising how few there are who appreciate or cultivate Haricot Beans. They are grown extensively in some gardens, but why in so few, or in such limited quantities, I fail to understand. I find them exceedingly serviceable, especially in times of comparative scarcity, for supplying a large amount of wholesome and nutritious food. It may be the taste for them has to be acquired, but with the assistance of a good cook this should prove no difficult matter. It is my privilege to have to supply a really good chef, and if we failed with Haricot Beans, he would not be well pleased; in fact, should I fail to grow a sufficiency, I should at once buy as many as were required. Last season was one of the worst on record for the proper ripening of the seed, but fortunately I did not rely exclusively upon one variety, and was able to meet the demand. I find any white-seeded kidney or runner Bean will answer the purpose, and accordingly sow long rows each of White Dutch and the smaller seeded Running Haricot, and in addition a large breadth of Carter's Longsword. The two former are treated exactly the same as Scarlet Runners as detailed in *THE GARDEN* (p. 407), but shorter stakes suffice for the Running Haricot. We generally thin out the pods of the White Dutch for the kitchen; these in all but the flowers and seed resemble ordinary Scarlet Runners, and are extensively grown in some districts in common with them. Care, however, is taken not to do more than thin out the pods, as it is of the greatest importance that the crop be secured as early in the season as possible in order to ripen the seed before frosts intervene.

THE ONLY VARIETY that ripened properly last season was Carter's Longsword. This is a very prolific white-seeded dwarf kidney Bean, and serviceable for gathering when in a green state in common with other kidney Beans; or if the whole of the pods are saved and the seed ripened it is still more profitable. Even these did not ripen the seed in the open last season; on the contrary, the plants had to be pulled up early in October, bunched, and hung up in a dry shed where a fire was burning the greater part of each day. Here they ripened off the seed fairly well; at any rate, it was fit for cooking. The seed of this variety is usually sown during the first week in May on a warm, sheltered border. The rows should be 2 feet apart, the plants eventually thinned to about 6 inches apart. They are lightly moulded up after rain and staked; otherwise they are apt to break down, in which state the seed ripens imperfectly.

COOKING.—Haricot Beans need not necessarily be dried; in fact, they are preferred here when gathered for immediate use while yet the pods are green. They may be prepared in the following manner: Half fill a stew-pan with water, and when this is boiling throw in the Beans, adding a pat of butter and a small quantity of salt. They should boil till quite soft, when they should be drained in a colander. Next let them be put into a stew-pan, adding 3 ounces of fresh butter, a little pepper and salt, chopped Parsley, and Lemon juice. Let the whole be tossed together until thoroughly mixed, and when dished up surrounded with "croutons," that is, thin pieces of bread cut into various shapes and fried in clarified butter. The foregoing relates to fresh seed, but when it is dried it is necessary to steep it in cold water for five or six hours previous to its being prepared for the table; and, in addition, it should be put on in cold water to boil. GROWER AND EXHIBITOR.

Chou de Burghley.—"H. P. J." may depend on this Cabbage Broccoli for both hardiness and good quality. It is one of the very best vegetables of its kind he can grow. —J. S. W.

POTATO SETS.

THOUGH now late in the season, yet "J. S. W." has opened an interesting topic, and one well worthy of discussion. I do not disagree with the late Mr. Robert Thompson's observations as quoted by "J. S. W.," because it is true that large tubers, being of larger build and containing larger reservoirs of sap as a rule do push the largest shoots; indeed, there can hardly be two opinions as to this fact. Still, it is qualified so far by the habits of various kinds, as, for instance, one sort will, on a given surface, produce only say three or four shoots, whilst another will furnish twenty. Thus we know that in most of our best English kidneys it is the rule, let the tuber be ever so large, to yield but one, two, or three very strong shoots at the bud end, because the bud eyes are nearly all at that end. On the other hand, in the American Rose and its allies bud eyes are all over the surface of the tubers, and everyone will start at the same time, so that whilst all the strength of the tuber in the one case goes to the building up of two or three shoots, in the other case it goes to build up twenty. If again two-thirds of the buds of the Rose tubers were taken out, it is doubtful whether those which remained would be much stronger in consequence, because each bud has its sap channel in that case, whilst in the kind that has its buds at one end only, the sap channels are few and large, and all converge from one end to the other. Round Potatoes are in many cases most active in breaking at every eye, whilst others will start one, and that the prominent bud eye only, all the rest for a time being dormant. Break off the first shoot, however, and all the rest will push up. Here lies the chief evil which results from the foolish practice of so storing seed tubers that the sprouts have to be removed not only once, but sometimes twice before planting time comes.

Now, whatsoever may be said in favour of small sets, it has long been most fully demonstrated that crops are greater or lesser just as sets are large or small, provided the soil be of equal quality. On the other hand—and no doubt this is the point which "J. S. W." is aiming at—the real question is, what size of set—all other things being equal—will give the most profitable results with the least waste? for it is waste to plant sets big enough for consumption if smaller ones will do as well. In saying this, exception must of course be made in favour of big tubers cut into several sets, but, as a rule, that is not a good plan to adopt. Where, however, compelled by circumstances to plant large sets—and I can get two, three, or even four good eye-buds or shoots—I never hesitate to cut, as I am sure such is, as I have shown, the distribution of the sap channels in the tuber that each set will get its proportion of sap to build it up. But after all the great thing with the shoots on sets, large or small, is that they shall fluid when planted not only early nutriment, but in such a form as shall force a rapid and robust growth. It is an old story to say that Potato shoots, as long as the sets are kept stored dry and in light, have no inherent power to push beyond an inch or so in length; that fact shows how much the power of the set to make growth is limited until it comes into contact with either moisture or soil. New roots already in embryo are pushed at once, and the moment these feel soil and manure the development is wonderful. If small sets have an ample supply of stimulant at hand the growth will often prove as strong as is produced by bigger tubers if in poorer soil. It will thus be seen that stimulating the rootlets at the critical moment of first development seems to be almost of greater importance than is the size of the respective sets. Growers of Potatoes for exhibition secure as fine crops as can be grown, and they do not plant big sets, but those of medium size, carrying one or two shoots, all the rest having been removed. The object is to secure tubers of even size, not so many perhaps as would be the case if all the eyes were left, but giving as much weight and perhaps more because the whole of the tubers are larger. It used to be recommended, to secure the same result, to remove all the weaker

shoots when well through the ground, leaving only two or three of the strongest; but that was not a desirable way to secure the desired end. By thus thinning the shoots few or no small tubers result, and the smallest are really fine seed, whilst the largest are either first-rate for exhibition or for table. In measuring the produce of a given extent of Potato plants it is as important to know the proportion of table tubers as it is to know the entire bulk, as if a considerable portion be small the value of the crop is very much lessened.—A. D.

—No doubt there is a good deal of truth in "J. S. W.'s" opinion in your issue of April 28, that the crop of Potatoes from whole small seed will be equal in size and weight to large seed cut, but another most important consideration is, will they keep up as healthy a strain? Long observation has convinced me that to resist disease and to keep up a first-class strain the very largest tubers should be planted, either cut in two or planted whole and far apart.—Q. Q.

MARKET GARDEN NOTES.

WHITE LILAC.—For some years past a friend of mine has forced this with considerable success in cellars, getting the plants into bloom about Christmas, at which time white flowers of all kinds are much sought after. As soon as the foliage drops, good strong bushes with well developed buds are taken up carefully and are laid in moist earth, and a constant temperature of about 60° is maintained. The flowers realise about six shillings per dozen, a price which ought to be a paying one, seeing that growing them under the conditions necessary to ensure the requisite purity does not demand the outlay for firing, nor indeed the labour which would be needful to maintain the same heat under a glass roof: It is easy to perceive that where no air or light is admitted the cost of flower forcing is comparatively a cheap and easy matter, and it is probable that cellars, caves, or sheds which may be available could scarcely be more profitably employed than for the production of white Lilac. When my friend first conceived the notion of turning the cellars of his dwelling into a forcing house, he fitted up a heating apparatus in them, the same consisting of a small hot-water boiler, with pipes attached, which thoroughly warmed the place with but little trouble and expense. All went well until the flowers were in just the right condition for market, when an escape of sulphurous fumes from the boiler completely ruined them. Profiting by this severe lesson, my friend removed his boiler to the outside of the building, and now forces his Lilac with ease and entire absence from danger. One thing especially the grower of white Lilac has to guard against, and that is too high a temperature, especially when the buds are bursting. I once received a lesson in the matter which I have never forgotten. Wishing to get some flowers in by Christmas, and having no heated shed or suitable convenience, I constructed a hut of mats under the stage in the stove, and put the same large well-budded bushes therein. Had I fitted up the coolest end of the house, I should have got on all right; but, forgetting the old proverb of "more haste less speed," I made my arrangements at the hottest portion of it near the boiler. The result was very disappointing, as through having to fire hard during a period of severe weather, the shoots made a rapid growth, the greater portion of them showing no bloom at all. With a temperature of 55° to begin with, running up some 10° later on, I should have obtained some good spikes of bloom.

ARUM LILIES.—Formerly the season for these scarcely commenced before Christmas, and it was only at that time and at Easter that the flowers could be said to command remunerative prices. Within the last few years this flower has increased wonderfully in popularity, and not only is this the case, but it is "asked for" now at a period when in times past it would have been but a drug in the market. This is, I believe, in a great measure due to the now almost universal custom of holding harvest festival services in our churches, as well as to the extensive and lavish use of flowers therein

throughout the year, white flowers, of which the Calla is queen, being in especial demand. Last autumn a grower of my acquaintance obtained 6s. per dozen for flowers of medium excellence; had they been quite up to market form, they would have brought him at least one-third more. This is not so much as they realise later on, but probably is quite as remunerative as the higher prices obtained by means of constant firing during the coldest months of the year. Moreover, getting in of a crop of bloom so early allows the bringing of successional batches along for Christmas and later, so that the glass may be made to earn more than it otherwise could. Some kind of special culture is needed to induce the Calla to bloom with certainty in autumn, and this, I am told, consists principally in selecting plants which have not bloomed or the strongest offsets early in the year, and growing them along as freely and strongly as possible through the summer, getting them under cover at an early date, and firing as soon as the nights get cool.

PELARGONIUM DUCHESS OF EDINBURGH.—It is really wonderful the quantity of bloom that good plants of this decorative variety yield. For a period of six weeks the same plants continue to throw up good trusses, and as the flowers are pure white, with a blotch on the upper petals, they sell well in Covent Garden. A friend of mine has been cutting from well-established plants in 6-inch pots for some weeks past, and there are yet many flowers to expand. The habit, too, of this Pelargonium is so good as to form a model of what a market variety should be in this respect. A gentle warmth of about 55° brings it into bloom about the middle of March, but it is an excellent forcing kind and may be got in in fine condition at a much earlier date. If the plants are to be grown for cutting only I would advise that two-year-old ones be employed, as in proportion to their size they seem to produce a larger amount of flowers than younger ones. J. C. B.

JAPANESE PEPPERMINT.

IN more than one periodical the botanical name of this plant has been given as *Mentha arvensis* var. *purpurascens*. It will be well, therefore, to point out that this is an error before the statement is further copied and the mistake perpetuated. The plant has green foliage, with not a trace of purple, and less deserves the name *purpurascens* than the true Peppermint (*Mentha piperita*), of which a purplish-leaved form is well known. The mistake probably arose in the first place in a printer's error. The history is as follows: For some years past a large quantity of a substance called menthol has been imported into this country, and extensively used as a topical application for the relief of neuralgia, and in some instances as an antiseptic. This substance in appearance closely resembles Epsom salts, and consists of crystals deposited in the oil of peppermint distilled from the Japanese Peppermint plant. This oil when separated from the crystals, is now largely used to flavour cheap peppermint lozenges, being less expensive than the English oil. The crystals deposit naturally in the oil upon keeping, but the Japanese extract the whole of it by submitting the oil several times in succession to a low temperature, when all the menthol crystallises out from the oil and falls to the bottom of the vessel. The source of the Japanese peppermint oil has been stated to be *Mentha arvensis* var. *javanica*. On examining several specimens of this plant in our national herbaria I found that the leaves tasted like those of the common garden Mint (*Mentha vioidis*), and not at all like Peppermint, and that therefore the oil and menthol could not possibly be derived from this plant.

I then asked my friend Mr. T. Christy, who takes great interest in medicinal plants, to endeavour to get specimens from Japan of the plant yielding the oil. After many vain attempts he at last succeeded in obtaining live plants. These were cultivated in his garden at Malvern House, Sydenham, and when they flowered I examined the plant and found that it differed from

other forms of *M. arvensis* in the taste, in the acuminate segments of the calyx of the flower, and in the longer leaf-stalks; the leaves also taper more towards the base. Dr. Franchet, the greatest living authority on Japanese plants, to whom I sent specimens, confirmed my opinion as to the variety deserving a special name, and M. Malinvaud, a well-known authority on Mints, suggested the name *piperascens*, which I adopted, calling the plant *Mentha arvensis* var. *piperascens*. Specimens of the plant kindly lent by Mr. Christy for the purpose were exhibited by me at an evening meeting of the Linnean Society, and by a printer's error in the report of the remarks then made the name of the plant appeared in print as *Mentha arvensis* var. *purpurascens*. I trust that the present note, through the medium of THE GARDEN, will prevent the perpetuation of this error. This is the more important, as I hope that the plant will come into cultivation in this country. It is a robust plant of rapid growth, as easily cultivated as the English Peppermint, and seems to require less moisture, and is therefore capable of cultivation in a great variety of localities. The increasing demand for menthol, which can only be procured in small quantities from the English Peppermint, and the high price of English peppermint oil, lead to the hope that instead of importing menthol from Japan, it will be prepared in this country from the Japanese plant. With the appliances of more advanced civilisation, it ought to be possible for the oil and menthol to be made in this country at a less price than the Japanese products now cost.

At the present time large quantities of cheap peppermint oil are imported into this country from the United States, and Chinese oil is imported into Bombay for use in the Government medical stores. There is no reason why this should be the case if the Japanese plant were cultivated in this country. In Ireland, where labour is cheap and the climate moist, this crop might afford a valuable source of income to enterprising cultivators. It may be interesting to note here that the plant used in China closely resembles the Japanese one, differing chiefly in the narrower and more glabrous leaves. I have therefore named it *Mentha arvensis* f. *glabrata* from specimens sent to me from Hong-Kong by Mr. C. Ford, the director of the Botanic Gardens there. E. M. HOLMES.

FRUIT GARDEN.

EXTENSION VINE BORDERS.

THE conclusion to which "J. C. C." (p. 375) comes in advising an all but unlimited space for the roots of Vines to extend in is not likely to be accepted by those who have had much experience in Vine culture. The roots of Vines, like those of other free-growing plants that naturally take a horizontal direction, have a constant disposition to extend and frequently travel much further than is supposed; they do this regardless of whether the soil is suitable for them or not, and often where such is within their reach go deep down into bad material such as prevents their bearing as they ought to do. "J. C. C." admits that a few large roots may find their way into undesirable quarters; where this happens, if examined it will often be found that all except a few that can exert little influence on the well-being of the Vines have got astray. In exceptional localities where the soil, both surface and underneath, is naturally suited to Vines, an unlimited root-run may be an advantage where it can be given without the roots getting where they will be interfered with. In my neighbourhood the soil is strong and heavy, yet so full of flints, that when turned up it looks as if a coat of gravel had been spread on it, and in most places the deeper one goes for several yards the more flints there are in it; so well do Vines like it, that they keep in good condition after their roots have gone very deep down, as well as far beyond the limits of the widest Vine border. But for one locality where this can be permitted with impunity there are two or three

where it would be fatal to anything better than middling crops of third-rate fruit.

DEEP NARROW BORDERS are not likely to find many advocates at the present day, although under exceptional circumstances narrow ones are sometimes a necessity, and the crops that in skilful hands for many years that can be got out of them is surprising. Of all plants in cultivation Vines are the last that any hard and fast line should be laid down for as regards the extent of the root room to be given them. Where there is nothing in the natural soil inimical to the roots it is a mistake to confine them to a narrow border; but even where the soil is thus suitable it is also a mistake to let them run at will over a kitchen garden, for they will not stop at the 60 feet or 70 feet which "J. C. C." names. Where good gardening is carried out deep trenching is a practice not to be lost sight of, and where this is to be done how are the Vine roots to fare? In most cases where the roots have extended 60 feet or 70 feet away, if the ground is examined it will be found that there is scarcely a feeding fibre for half the distance next the stems of the Vines, all the roots sustaining them being in the outer part of the space. In far the greater number of places much better results are attainable with

A FAIRLY MADE BORDER than with the roots in the ordinary soil. A very common mistake in Grape growing is to look upon making a Vine border as an event in a lifetime, once done, seldom afterwards to be touched. There seems often to be a horror of interfering ever so little with the roots, as if there need be any loss of time or expenditure in material, or labour of a serious character entailed. The fallacy of this is shown by the fact that the most successful growers, both as to quality and quantity, are to be found amongst those who are continually from time to time at short intervals renewing a little of the soil, lifting a few of the roots, and encouraging plenty of feeders within a reasonable distance of home. This course, I venture to say, will in most localities give better crops, and enable the Vines to continue fruitful better than making unreasonably big borders or letting the roots run where they like, which latter, as I have stated, may do in the comparatively few places where the natural soil and other circumstances are alike favourable, but in most places such treatment is the reverse of calculated to obtain the best results. T. B.

SPRING AND SUMMER MANAGEMENT OF FRUIT TREES.

THE cold experienced during April, just as fruit trees had budded, has been the means of retarding growth, and it always follows when this is checked that the young shoots become infested with insects, the worst among these being aphides, which curl the leaves, and unless held in check or destroyed, soon do irretrievable damage by ruining the health of the plant. The trees they most affect are Peaches and Nectarines, which become a ready prey to their attacks and suffer more quickly than most others, and it is to these therefore that attention should be first directed. In order to wage war successfully, the trees must be divested of all superfluous shoots by a general disbudding, which clears the field as it were to wage war with the enemy, and he can then be assailed in a variety of ways. The most simple, and perhaps the most effectual, as well as the safest, is by means of Tobacco dust, which may be puffed on to the points of the shoots and among the curled leaves by means of a distributor which all nursery and seedsmen keep and sell for the purpose. The Tobacco powder is so potent and quick in its action, that it fairly staggers the insects, and shortly after its application they may be washed off and dashed to the ground. To carry this out there is nothing equal to a garden engine, as by its aid water can be ejected and sent on to the foliage with some force, but at the present tender stage of the leaves care is needed, or the dash of the water will bruise and tear them to pieces. To prevent this, the jet or stream should be broken up by placing the finger against the delivery tube

or keeping the engine at a distance of 10 feet or 12 feet from its work, as then the water cannot hit hard. If a garden engine cannot be had, a syringe will answer the same purpose fairly well, but to keep trees at all clean it is absolutely necessary to use one or the other. The time they should be brought into requisition is either early in the morning or towards night, the latter being best, especially when the season becomes more advanced and the days warmer, as then the water has a very refreshing and strengthening effect on the trees and wards off red spider, a pest that otherwise is apt to be very troublesome during the summer, but which clear water holds in subjection. Next to Peaches and Nectarines, Cherries are the trees most liable to the attacks of aphids, and the Cherry louse and black fly are most difficult to kill, as they have tough skins, which are protected by an oily coating that repels wet and throws most insecticides off. The best remedy against these hardy aphides is nicotine soap, which is a most valuable preparation, and used in the proportion of about 4 ounces to the gallon of water destroys the black fly at once. The most economical way of applying it is to have a bowl or other similar handy vessel and dip the shoots in, which may be quickly and easily done by gently bending them down. Previous to taking this in hand, all foreright shoots should be stopped back to three leaves, and only those left that are required for laying in to extend the branches and for filling up bare spaces on the walls. By doing the stopping early it often saves trees becoming attacked with insects; and not only that, but it makes the spurs fruitful, by causing the formation of flower-buds at the base of the shoots, where the strength is then concentrated, instead of expending itself and going to waste. Morello Cherries require different treatment from the dessert kinds, as Morellos bear on the young wood, and in the management of these as much should be left and nailed or tied in as there is room for without crowding, the shoots that should be chosen being those best situated on the branches and close to the wall. Plums of all kinds fruit most freely on spurs, and here again the stopping of the shoots plays an important part for reasons already stated, and the same with Apricots which, like Plums, cannot well be too closely nipped in, as the nearer the spurs are to the wall the better protection they get. In cases where spurs are long and dense they may be considerably improved by an entire removal of some of the end shoots, which will let in light and air and strengthen the others below. By a judicious and timely pinching and thinning in this way, very little autumn or winter pruning will be needed, as the finger and thumb may be so used as to regulate the growth of a tree to a nicety. The spur system is also the best for Pears and Apples that are grown on walls or as pyramids, espaliers, or bushes, but the stopping of these like the others must be done early, and to have regular crops annually it is necessary for the fruit to be thinned, for if a tree is too heavily loaded this year it will ease itself by not bearing next. Mulching over the roots of trees that have much fruit on them is a great help to them, and an additional assistance may be afforded by a soaking or two of liquid manure. S. D.

Fruit crops in Suffolk.—These have been very promising, but now there appears very little hope of a large crop of fruit, except in the case of the later and more hardy kinds, as not only has the weather for some time past been most fitful and cold, with keen north and north-east winds, which have on several occasions approached almost to a gale, but on the night of the 3rd inst. we had quite a sharp frost, making the Grass stiff and coating it over with a hoary deposit. This was followed by a heavy fall of hail, betokening further mischief, and should it clear up and freeze again, the consequences will be most serious, for Plums, Cherries, and Pears are just at that critical stage when they are most liable to injury. They are in full flower; the tender stigmas are therefore quite exposed, and if these are blackened it is impossible for fertilisation to take place. Fortunately, everything is very dry, which is much in

favour of the blossoms. Apples are too backward to take much harm, and as they are late and the trees remarkably full of flower-buds we may get a good crop.—J. SHEPPARD, *Woolverstone Park, Ipswich.*

KIEFFER'S HYBRID PEAR.

I SEE that Mr. Hovey represents this hybrid Pear as being of poor quality. That may be his opinion; people's tastes differ; and a fruit that is pleasant and agreeable to one person may not be so to another, and the quality of different specimens of the same variety of fruit may differ; we sometimes find Lawrence Pears of poor quality bitter and disagreeable, though the Lawrence is considered a good Pear. The same may be said of other varieties. There are several circumstances to be observed—the Pear should be well grown on a healthy tree and properly ripened. It requires several years to establish the reputation of a new fruit. At one time the editor of the *Germantown Telegraph*, a popular and influential paper, denounced in strong terms the Kieffer Hybrid Pear as worthless—"totally worthless in (his) estimation—at least as a table fruit." Since then, having become better acquainted with its merits, he has changed his views, and placed it in the select list of valuable fruits recommended to his numerous readers. It is natural for the introducer of a new fruit to esteem it highly, and no doubt Mr. Hovey esteems the Hovey Seedling Strawberry, introduced forty years ago, higher than the Albany Seedling of more recent date; yet the verdict of fruit growers in our wide country of fifty millions of people is against him, if we judge by the catalogue of the American Pomological Society, where there are but seventeen stars given to the Hovey and sixty-three to the Albany Seedling. Some are fond of the peculiar piquant aroma of Kieffer Pears, and during the autumn I indulged in eating one or more almost every evening before retiring in preference to the Lawrence Pear, of which we had plenty. I never claimed for the Kieffer best quality. In a description given on a former occasion I rated it as "simply good; about equal to the Duchesse d'Angoulême." In reply to this Dr. Thurber says, "We think he does what is unusual with introducers of new fruits, *i.e.*, underestimates its quality." Our recollection is that it has a refreshing briskness that the Duchesse has not. The fruit, while it may not come up to the high standard of "best," is of sufficiently good quality to be acceptable to those who esteem the Bartlett, which, while regarded as second or third-rate by critical amateurs, meets the general taste, and every candidate for popular favour must stand comparison with that best known of all our Pears. We have not for a long time seen a fruit that appeared to unite so many elements of popularity as Kieffer's Hybrid, and shall be much disappointed if it does not prove to be a valuable and profitable market fruit. The tree is a strong and vigorous grower, bears early, is very productive and apparently as free from disease as the sand Pear, which is one of its parents. The fruit is of good size, of an attractive colour and keeps well, never decaying at the core.

THE CENTENNIAL FRUIT COMMITTEE gave it a prize medal and certificate, as introducing a new race of great excellence, and at the fifteenth annual exhibition of the Pennsylvania Horticultural Society it received "honourable mention." It was tested and found of good quality. And at the annual exhibition of the Burlington County Agricultural Society, held in 1881, it was awarded the only prize medal given to any Pear. The editor of *The Gardeners' Monthly*, in the January number, 1880, says: "We have eaten fruit of the Kieffer Pear, which was equal in luscious richness to any Pear we have ever eaten. The whole of the judges at the Centennial, who had some fruit before them, also seem by their report to have had a favourable experience of the Kieffer. Now, if there are some gentlemen who have had fruit of it that was not commendable, it is no more than general experience with other fruits, for everybody has had Vicars and Flemish Beauties and other fruits that were not worth eating. If these

poor samples happen to be sent for opinions, of course, no editor can do anything else but speak of them accordingly. We expect some time to have a poor specimen of the Kieffer as well as of any other kind, but that will not alter our opinion about the excellent fruit we have tasted."

ONE EXTENSIVE PEAR GROWER who exhibited 300 varieties of Pears at one exhibition of the Pennsylvania Horticultural Society, in Philadelphia, stated that "his faith in the Kieffer as the coming Pear was supreme." He had the past year about 200 bushels of this variety, all grown upon grafts set two years ago last spring. The fruit sold readily in the market at from 2s. to 3s. per half-peck, and selected specimens at from 1s. to 2s. each. He says that the Kieffer and Le Conte Pears will revolutionise the whole business of Pear growing, and make Pears more plentiful than heretofore. Another extensive fruit grower in this neighbourhood, who has been sending Kieffer Pears to Philadelphia market for three years past, finds the demand and price have increased each year as the fruit became known. In the autumn of 1880 Kieffers sold at 1s. a half-peck; in 1881 they brought 2s. a half-peck, while good Lawrence Pears were selling in the same market at 10d.; and in the fall of 1882 he had 40 bushels, mostly grown on young grafts set two years last spring, which sold readily at from 2s. to 3s. per half-peck, and he disposed of several bushels to one person at £1 4s. per bushel. Kieffers also found customers in Massachusetts, as several bushels grown in Burlington County, N.J., were shipped to Worcester, Mass., and although delayed a week by an accident on the railroad, they sold readily on arrival at £1 4s. per bushel, the same as in Philadelphia. The writer of this imported in 1840, from France, 312 varieties of best selected Pears and carefully planted them; since then he has added to the orchard many others that were highly recommended, but has never found any other variety that combined so many desirable elements of profit to the fruit grower as Kieffer's Hybrid Pear, which is a strong, vigorous grower when propagated on Pear stocks from buds cut from healthy standard trees having no Quince sap in them. It is an early bearer, will produce fruit the second year from the graft set in older trees, and on young trees when three years from the buds, and it is enormously productive. The fruit is large, measuring from 10½ inches to 11 inches round, and weighing from 10 ounces to 12 ounces each, and very uniform in size. It is of double turbinate shape, and pointed at each end; skin greenish yellow, with some russet; flesh white, buttery and juicy. It ripens in October, and will keep through November when other Pears are scarce and high-priced. This Pear colours up beautifully, becoming rich yellow, with a red cheek next the sun. It does not rot until very ripe, and remains firm at the core to the last. Fruits of it have been shipped to England, and bear transportation as well as Apples. Possessing, as it does, so many good qualities, this variety will occupy the same position among Pears that the Concord does among Grapes, and the Albany Seedling has heretofore among Strawberries. The Kieffer is

THE PEAR FOR THE MILLIONS, and can be grown as easily and abundantly as Apples, and sells much higher in market. Delicious flavour is not the only property for fruit growers to look for. The most important considerations for those who wish to grow fruits for profit are to obtain trees and plants that are hardy and productive, yielding an abundance of fruit of fair quality that carries well and sells well. Fruits that cannot be grown to a profit will not be much grown for market. My advice to the young fruit grower is to plant what pays best. We have planted and tried to grow the Orange, Hornet, and other choice varieties of Raspberries, but could make no profit from them here; while ten acres of Brandywines—dry, firm berries, not of best quality for table use—yielded one season 26,300 quarts which carried well, looked well, and sold for £868, and after deducting all expenses, left a nett profit of £560—an average of £56 per acre. Apples that are the most delicious for table use are not the most profitable to

grow for market. Maiden's Blush and Early Hagloe, second or third-rate Apples, are very profitable and largely grown; while the luscious Summer Pearmain and Early Joe, Apples of first quality, are not profitable nor much grown, one tree of each being plenty for anyone to have. The Seckel, the most delicious of all Pears, is not very profitable, nor much grown here by market men. We have planted trees and tried to raise the Washington, Jefferson, and Coe's Golden Drop, Plums of the finest quality; but they could not resist the Curculio, and we got but little fruit and no profit from them, and discontinued growing those varieties, while the Wild Goose, a little red Plum, was yielding more than a bushel to a tree, which sold readily in market at 12s. per bushel; they are very profitable, and are being planted largely. Peaches and Bartlett Pears have been and still are the most popular fruits in their season. Unfortunately, they both ripen at the same time, and when both are abundant and cheap, there is no need of, nor much call for, other fruits. Fortunately, Kieffer Pears come in later, and being larger, handsomer, firmer, bearing transportation better, and having no competition in the market, sell higher than either Peaches or Bartlett Pears in the season. Kieffer Pears come at a season to occupy a vacancy not filled by any other fruit; and fruit growers may cultivate all the Peaches and Bartletts to which they can properly attend, and have another orchard of Kieffers to come in later yielding more profit than both of the others. —*Rural New Yorker.*

Fruit prospects.—Mr. Rutland, writing from Goodwood, says: I have just had a look over our fruit trees and am in hopes that we are going to have a much better crop than might have been expected from the trying weather we have had of late. Apples and Pears are very promising indeed; Peaches and Nectarines will be a fair crop; Cherries promising also. Currants, Gooseberries, and Strawberries, Apricots and Plums appear to have suffered most in this locality. Kentish Cherries, we hear, are safe in most places, though the ground under them was covered with snow when they were in bloom.

Small-flowered Peaches for forcing.—"W. W. H." (p. 375) asserts that small-flowered Peaches and Nectarines are best for forcing, but in this I must differ from him. Dr. Hogg Peach and Lord Napier Nectarine, each bearing flowers as large and beautiful as any I know of, are in all respects equal to the small-flowering varieties recommended by "W. W. H." for early forcing, and in some important points superior to them.—R. WESTCOTT, *Raby Castle, Darlington.*

—There are doubtless some Peaches better adapted than others for forcing, but as to the size of their flowers having anything to do with their adaptability for the purpose, I should very much doubt. If that be so, how comes it that the good old Noblesse, which has perhaps the largest bloom of any Peach, sets so freely, and is such a favourite for planting indoors? Then, again, there are the large-flowered Nectarines, which only differ from Peaches in their skins; and what kind can set with greater freedom than Pitmaston Orange, Hawick Seedling, or Lord Napier, all of which have larger flowers than any other sorts? Those that set freest indoors are the sorts that set most readily out, and these are the hardiest and best suited for walls, for if we want to grow Peaches there Royal George, Violette Hâtive, Grosse Mignonne, Stirling Castle, Bellegarde, and Noblesse are those which most planters choose for the purpose, and any of these are equally good under glass, and the same with the Nectarines just mentioned.—S. D.

Abercainey Grape.—I am obliged to Mr. Brown (p. 403) for his correction in this matter. No doubt I am in error about the raiser of the Grape. I only recorded impressions received from casual conversations many years since. It is more satisfactory to have the distinct character of the variety itself certified by Mr. Brown.—J. S. W.

TREES AND SHRUBS.

ADVANTAGES OF A HOME NURSERY.

The numerous advantages of a well stocked home nursery, especially where planting is extensively carried on, are so well known and appreciated by every forester, that comment on this subject seems almost unnecessary; however, as the season of nursery re-filling is now upon us, a few remarks on the subject may not be out of place. I do not propose in the present paper to dilate on the details of nursery management, my object being more to dwell on the advantages of a home nursery for the rearing of plants for special purposes, such as the planting of barren, exposed districts, as well as the convenience of having at hand a stock of plants suitable for all emergencies, and whose hardiness can, to a great extent, be relied upon. Where ornamental planting, game coverts, or hedging is performed on an extensive scale, the convenience of a home nursery cannot be over-valued, the plants being always at hand and of the size and in the quantity required, thus obviating the necessity of sending to a distance for these when wanted. The advantages in these cases are too well known to require comment, and plants, more especially those of a large size, sent from a distance cannot, after packing and transmission by road and rail, be expected to succeed equal to those raised and planted on the same day. The extra soil or ball with which large plants can be removed for a short distance is also much in their favour, but which is next to impossible where packing and transit have to be resorted to. It is well known that too sudden a change from rich, well-sheltered nursery borders to bare, exposed hillsides often proves fatal to young plants; and when we consider that few public nurseries are at a greater elevation than 300 feet, the necessity of proprietors rearing their own stock whose plantations are, perhaps, upwards of 1000 feet above sea level will the more readily be seen. There are certainly difficulties to contend with in planting high-lying ground, more especially if the soil is poor and the situation exposed, and in these cases the advantages of using hardy plants that have been frequently transplanted in a well-chosen home nursery are only too perceptible, especially when contrasted with others that have been grown under more favourable circumstances and in a sheltered position. Some plants seem better adapted than others for this removal, but in the majority of cases the shock sustained by transferring from low-lying ground to that at a great elevation is only too apparent, and from which the plants seldom recover. A good deal of comment has taken place as to the necessity of

REARING TREES FROM SEED sown on the site of the future plantation; and, although the suggestion has many points in its favour, still, artificial planting is better adapted to the wants of our country, and not at all likely to be superseded by artificial reproduction, which is more fitted for countries differently situated from our own. The nursery treatment of plants is, therefore, sure to remain a prominent feature of British forestry, and as such the soil and situation, as well as most successful treatment of these, so as to produce plants suitable for the positions they are intended to occupy, will require due consideration, and vary much according to the situation of the estate and ground to be planted. In choosing the

SITE OF A HOME NURSERY, a good deal, as before stated, will depend on the general elevation and exposure of the estate. The situation should neither be too much exposed nor yet sheltered, but partaking to a certain extent of both, and with a southern or western exposure; for although too sudden a change from sheltered to exposed ground often proves fatal to young trees, this should not altogether form a criterion for rearing such in situations unfavourable to the development of strong, healthy plants. The soil should be good friable loam on an open, porous sub-soil; but the quality of ground required for different seedlings is so diversified, that it is next to impossible to suit all within the small bounds re-

quired for a home nursery. As water is indispensable where seedlings are raised, as well as for numerous other purposes in the nursery, it is well to have provision made for a continuous supply, either by a stream running through the nursery ground or in close contiguity to it.

SIZE AND LAYING OUT.—From six to ten acres will be found sufficient nursery ground for most estates, but it is advisable to add a little more than is really required, so that the breaks may not all be under forest trees at the same time, but undergo, when found necessary, a course of green

way of shelter. The site chosen for the seed beds should be naturally sheltered, or failing this such artificial shelter as is found necessary should be provided, as exposure of the young plants to cold, cutting winds causes them to become stunted and bark-bound. In the management of a nursery the amount of care and attention required is certainly great, but any trouble as well as expense connected with starting and keeping it in good condition afterwards will be amply repaid by the increased value and superiority of the stock obtained: and as the subject of extended plant-

A tropical riverside scene.

crops, which will not only enrich, but clean the ground, and leave it in good condition for replanting with seedling forest plants, bearing in mind that farmyard manure should always be applied first to the green crop, and never directly to the plants themselves. Land intended for nursery ground should be thoroughly trenched to the full depth of the soil, and where necessary heavily manured or enriched by the addition of lime, vegetable soil, or loam, as the case may require. In laying out the ground into breaks it will be found convenient to have these either square or rectangular in shape, and, if possible, parallel to each other. The breaks may be divided by different kinds of hedges, which, when well kept, give not only a neat and tidy appearance to the nursery, but are highly beneficial in the

ing is one well worthy the consideration of proprietors owning exposed or otherwise worthless tracts of land, a step in the right direction will be the establishing and maintaining in good order a well-stocked home nursery. A. D. WEBSTER.

Penrhyn Castle, North Wales.

Ribes alpinum pumilum aureum.—This dwarf variety seldom exceeds 2 feet in height, and forms a dense-growing, much-branched shrub, thickly clothed with leaves of a bright golden hue, especially when first expanded, for though they do not become wholly green at any time, they partially lose their colour as the season advances. Its slow growth and rather spreading habit eminently fit it for rockwork and for places of limited

extent; a position should, however, be chosen for it where it would be exposed to the sun's rays, as the depth of colour is thereby much increased. I have not been very successful in striking this plant from cuttings made in winter after the manner of those of the Currant or Gooseberry, and the pieces removed were a loss to such a slow-growing subject as this *Ribes*; therefore, having a couple in pots, in the spring they were placed in rather a warm greenhouse, with the result that they broke into leaf and pushed out young shoots quickly, which attained a somewhat greater length than they would have done in the open ground. While these shoots were still succulent they were taken off for cuttings, inserted half-a-dozen around a 4-inch pot of sandy soil, put in a close case, and treated in all respects the same as *Fuchsia* cuttings. Treated thus, they struck readily, and, being potted off as soon as rooted, made another growth the same season.—ALPHA.

New seedling Rhododendron.—About twenty-five years ago I raised a seedling *Rhododendron*, which has only flowered once during that period, viz., last year, when it produced one truss of three flowers—the normal number apparently. There have been twenty-one flowers upon it this year, besides several bunches not yet expanded. As regards scent, it outvies most plants; my conservatory is perfumed with it from morning to night. In respect to perfume it is far before the *Brugmansia*. I think I have seen the plant somewhere, but not in flower. I have had it, as I have said, over twenty-five years.—J. SCOTT, *Merriott, Somerset*. [A beautiful variety, with large white blossoms of a delicate pink colour in the bud stage. In the absence of other kinds with which to compare it we cannot speak of its distinctiveness.]

SOUTH AND NORTH.

It is curious to note how similar the wayside vegetation of the world is, and how in every country we see old friends or types very much like those at home. In some very tropical countries, however, the change in vegetation is indeed great, and we are in a new world of fair and new forms, often, however, as in the case of the Banana and Plantain, shorn of their grace and fullness of form by the wind, which has equal respect for Passion Flower and Thorn Bush. The wind which strips the great-leaved tropic plant has on its way passed the Oak unharmed. Without going so far, however, as tropic lands, man has it in his power to form very beautiful aspects of vegetation in the open air. Such is the one illustrated opposite where the fine crest of the Date (nothing is handsomer when well grown in the open than this Palm) is tossed gently by the breeze. The scene is a moonlight one, and the moon's light is a good one for enjoying vegetation of the nobler exotic types. They seem more strange then, while the cooler night air and the scents of old greenhouse and stove plants add another charm to the scene. The great truth, however, that should never be lost sight of in observing matters of this kind is that the charms of our own vegetation are no less precious than those of any other country. The tendency is to believe otherwise. Much has been done to make people believe that it is the exotic in vegetation which is best worthy our attention. This is a great mistake. When we have seen all that the semi-tropic garden has to bestow, we long for the soft young greens and many flowers of an English spring. How much more welcome would our English spring be, if we gave the attention now bestowed on glass sheds and their many delicate occupants to the things that only ask for soil and sky. Few know the difference this would make to our gardens and the greater charm it would lend to country life. There are no gardens in the world could equal ours if we gave the noble outdoor vegetation the place of honour and of thought—if ceasing to regard what we have of it as a matter-of-course appendage to our varied splendours in the hothouse line—only fit for neglect or rudest labour, while all the "swell" gardeners are, like their choicest plants, under glass.

SOCIETIES.

ROYAL HORTICULTURAL.

MAY 8.

THERE was a good show of plants in the conservatory on this occasion, but the most remarkable feature was the unusually large number of new plants submitted to the committee who awarded no fewer than twenty-seven first-class certificates as follows, viz.:—

PHALENOPSIS SANDERIANA.—A lovely new species in the way of *P. amabilis*, but the flowers instead of being white are suffused with a delicate rose-pink, like those of *Odontoglossum vexillarium*. In foliage it is distinct from *P. amabilis* or any other species. It was shown by Sir Trevor Lawrence, Burford Lodge, Dorking, and Mr. Lee, Downside, Leatherhead, both of whom had admirable examples of it, that from Mr. Lee being the richest coloured.

AZALEA BARON N. DE ROTHSCHILD.—A new Indian Azalea, having large double blossoms of a rich plum-purple, borne profusely even on small plants. This is unquestionably among the finest double Azaleas yet raised, and will doubtless become popular. Both Messrs. Veitch and Turner showed this Azalea in fine condition.

HELIOTROPE SWANLEY GIANT.—Probably the finest of all the *Heliotropes*. Its flower clusters, which are enormous, and measuring about 15 inches across, are violet-purple in colour, the perfume, as usual, being strong and agreeable. It is one of the best new plants that have come this year from Messrs. Cannell and Sons, Swanley, who showed it on this occasion.

ODONTOGLOSSUM VEXILLARIUM ALBICANS.—A variety with almost pure white blossoms, the only colour being in the centre. The plant was shown by Sir Trevor Lawrence, and bore three fine spikes of large blossoms.

NEPHRODIUM RODIGASIANUM.—A handsome new stove Fern, having long pinnate fronds somewhat erect, though recurved, and collectively forming an elegant specimen. Exhibited by Mr. B. S. Williams, Upper Holloway.

MASDEVALLIA XANTHOCORYS.—Similar to *M. Shuttleworthi*, but much inferior to it in beauty. It resembles it in habit of growth as well as in the size and shape of the blossoms, but they are rather unattractive, being without the graining of purple which makes *M. Shuttleworthi* so beautiful. Shown by Sir Trevor Lawrence.

CYMBIDIUM DEVONIANUM.—A rare species introduced many years ago by the Duke of Devonshire. It belongs to the pendulous spiked section. The leaves are leathery and erect, and produced from slender pseudo-bulbs. The spike is nearly a foot long densely beset with flowers about 1½ inches across with sepals and petals of an olive-green, and a violet-purple labellum richly blotched with intensely deep crimson. It is a handsome plant. Exhibited by Mr. James, Castle Nursery, Lower Norwood.

ODONTOGLOSSUM ELEGANS.—A truly handsome Orchid, elegant in growth and attractive in flower. It is supposed to be a natural hybrid between *O. cirrhosum* and *O. Halli*, and appears to be intermediate between these two. The flowers have long sepals and petals somewhat twisted, and the lip is also attenuated. The colour is creamy white, heavily blotched with chestnut-brown. It bears long, gracefully arching spikes loosely beset with flowers. The bulbs much resemble those of *O. cirrhosum*. If not unique this is an extremely rare Orchid. Exhibited by Mr. E. Wilson, gardener to Mr. Pollett, Fernside, Bickley.

MIMULUS MOSCHATUS GRANDIFLORUS.—A new variety of Musk, similar in flower to *Harrison's*, but remarkable for its extreme dwarfness and compact growth, being only about 2 inches high. Dense masses of it thickly studded with bright yellow flowers have a pretty effect. Exhibited by Mr. R. Dean, Ranelagh Road, Ealing.

AZALEA SOUVENIR DE PRINCE NAPOLEON.—A single-flowered variety of the highest merit, and, moreover, distinct from the host of varieties of *A.*

indica now in gardens. The flowers are large, of good form, and have prettily crisped and wavy margins. The colour is a rich salmon-pink spotted with crimson and edged with white. It is an abundant flowerer and of good habit. Shown by Messrs. Veitch.

MASDEVALLIA ROSEA.—A new and pretty species, quite distinct from any other in cultivation. The flowers somewhat resemble in form those of *M. Harryana*, but the odd sepal is bent over the others and the tube is considerably longer. The colour is a carmine-purple, but variable in tone. It is extremely floriferous, small plants of it shown by Sir Trevor Lawrence being abundantly furnished with bloom, two or three of its slender stalked flowers being borne from one growth.

MIMULUS NOVELTY.—A Hose-in-hose variety, having large showy flowers of a bright crimson-buff colour, profusely borne even on small plants. It represents one of the finest strains of this class of *Mimulus* we have seen. Shown by Mr. R. Dean.

WORMIA BURBIDGEI.—A handsome-leaved plant allied to *Dillenia*. The leaves are large and broad, some being 18 inches by 10 inches, and of a bright green colour. On the upper portion of the stem, which is erect, are borne the flower racemes, which project almost horizontally. The flowers are circular, nearly 4 inches in diameter, and of a clear yellow. It is a handsome Bornean plant of easy culture and rapid growth. Introduced by Messrs. Veitch, who exhibited it.

MIMULUS MOSCHATUS RUBER.—The counterpart of the variety *grandiflorus* (also certificated), except that in this the colour is a reddish buff. Like the other, it is very dwarf, compact, and floriferous. Shown by Mr. R. Dean.

COLUMNEA KALBREYERI.—A plant having a singular habit of growth. Its leaves are about a foot long, arranged one above the other on stout, erect stems. Their upper surfaces are a sort of metallic green, while the under-sides are a vinous purple. The flowers are large and yellow, reminding one of those of a small *Allamanda*, and produced direct from the stem without stalks. Shown by Messrs. Veitch.

AURICULAS HOMER, ROYSTERER, A. LLOYD, ROB ROY, and RESPLENDENS.—All alpine varieties, finer than any that have been produced hitherto; some have creamy centres, others yellow, and all have ground colours of indescribably beautiful hues in all cases exquisitely shaded into lighter and deeper shades. These were all raised and exhibited by Mr. Turner, of Slough, and well did they all deserve the awards made to them.

AZALEA PRINCESS LOUISE.—A double variety of the Indian Azalea, having large full blossoms of a pleasing rose-pink abundantly produced on compact habited plants. From Mr. Turner, Slough.

COLAX JUGOSUS PUNCTATUS.—A variety differing from the type in the flowers being much more spotted with purple on a white ground. Not only are the lateral sepals spotted, but the dorsal one also. Shown by Mr. Lee, Downside, Leatherhead.

RHODODENDRON SCARLET CROWN.—Another of the beautiful seedlings of the Javanese section raised and exhibited by the Messrs. Veitch. It has large trusses of flowers of symmetrical outline, and larger than any older variety of a similar colour, which is a bright crimson-scarlet.

AURICULA DELICATA.—A double-flowered variety having large rosette-like blossoms of a soft creamy yellow tint. A distinct and beautiful plant, quite a new departure from the ordinary run of Auriculas. Exhibited by Mr. R. Dean.

AZALEA COMTE DE CHAMBORD.—A variety of *A. indica*, having single flowers of large size and good substance, and of a soft salmon-pink colour edged with white. Quite an acquisition among sorts of this colour. From Mr. Turner.

NEW AZALEAS were numerous shown by Mr. Turner, Slough. All were first rate varieties, particularly those certificated. Among the others were *Furstin Bariatinski*, white, flaked with carmine; *Madame Van Houtte*, salmon, crimson

spotted, and white edged; *Memoire de Louis Van Houtte*, a beautiful double, of a rich carmine; *Comte de Kerchove*, white, heavily blotched with crimson and white edged; *Versicolor* and *Rosea picta*, two very much alike, both having large white flowers flaked and spotted with carmine. With these Mr. Turner showed a group of *Auriculas*, show, self, and alpine varieties, all of which were in perfect flowering condition, as fine and even finer than those shown at the *Auricula* show a fortnight previous. The alpine varieties were particularly beautiful, and seldom if ever had they been seen so fine. Most of those shown were new seedlings, all of the highest quality as regards size of flower, symmetrical outline, and richness of colour. A group of about a dozen and a half specimen *Pelargoniums*, chiefly decorative varieties, was also shown by Mr. Turner, which, together with the *Azaleas* and *Auriculas*, made one of the most attractive displays in the show. A silver-gilt medal was awarded for this group.

RHODODENDRONS AND POT ROSES from Messrs. Lane & Sons, Great Berkhamstead, were a beautiful feature. The large standard bushes of *Rhododendrons* were superbly flowered, and represented some of the finest varieties. The group of about three dozen pot *Roses*, too, was good, and on some of the plants of such standard sorts as *La France*, *Anna Alexieff*, *Marie Baumann*, and others were some superb blooms, as fine as those of July. A bright display was also made by *Azalea mollis*, which Messrs. Lane had as a fringe to their *Rhododendron* group. The abundance of bloom on these small plants, and the soft and pleasing colours of their flowers rendered them very charming. A silver-gilt medal was awarded.

A SILVER-GILT MEDAL was also awarded to Mr. B. S. Williams, Upper Holloway, for a large and exceptionally choice group of plants, consisting of *Orchids* and other flowering plants, intermingled with *Palms* and *Ferns* in an effective manner. Among the *Orchids* was a huge specimen plant of *Cypripedium villosum*, carrying several dozens of flowers; also a fine plant of *Dendrobium Calceolus*, a species not often met with, but a very beautiful one with large pendulous spikes of rich yellow blossoms; *Cattleya Mendellii*, represented by some splendid varieties; *Calanthe veratrifolia*, with tall spires of white blossoms; and *Masdevallia Harryana grandiflora*, with large brilliant carmine-magenta flowers. The chief attraction, however, in the group was a very fine specimen of a richly coloured variety of *Odontoglossum vexillarium* named *splendens*. This was a huge plant in a 12-inch pot carrying nearly a dozen spikes of bloom. In this group there was also a specimen of *Cypripedium caudatum* bearing three spikes of flowers, the tails of which measured fully 26 inches—the longest we had measured; also *Azalea Phœbus*, a first-rate double variety, and *Crinum Kirki*, a new species with large white, crimson-striped blossoms produced on stout, erect spikes, the latter one of the most conspicuous of the plants shown by Mr. Williams.

A GROUP OF *NARCISSI* from Messrs. Barr & Son was again (the third time this season) a centre of attraction, the number of sorts being as large as ever, and the quality of the blooms as fine as on previous occasions. There was, however, a slight change in the composition of the group. The *Trumpet* varieties were fewer, but the incomparables, and especially the poetical types were more abundant. The varieties of the *Poet's Narcissus* were particularly admired, and scarcely less so its near neighbour, the *Burbridge* section, which intermingle the characters of the *Peerless* and *Poet's* section in a beautiful way. A silver Banksian medal was awarded to Messrs. Barr & Son for their group, which we were pleased to observe was more tastefully arranged than we have hitherto seen it this season.

DOUBLE PETUNIA blooms of high quality, some good plants of the double *Mignonette*, a fine variety, and some well berried potfuls of the little *Nertera depressa* came from Messrs. Cannell & Sons, Swanley. A large group of a new golden *Fern* named *Gymnogramma Lauchiana grandiceps* came from the raisers, Messrs. Dixon,

Amherst Nurseries, Hackney. The fronds are elegantly cut, covered with golden powder, and broadly tasselled at the tips, giving the plant an elegant and beautiful appearance. It is undoubtedly an acquisition to the list of stove *Ferns*. Another beautiful *Fern* was shown in quantity by the same exhibitors. It was named *Athyrium Goringianum pictum*. It is of dwarf growth, and has finely cut green fronds marked along the ribs with a purplish colour. It is apparently a greenhouse *Fern*, and a most desirable one.

ORCHIDS from Mr. James, Castle Nursery, Lower Norwood, included two uncommonly fine varieties of *Cattleya Mendellii*, one with large broad, white sepals and a richly toned frilled lip; the other named *rosea*, with the flowers suffused with a beautiful rose-pink throughout. A variety, too, of the *Foxbrush* *Orchid*, *Aeides Fieldingi*, was also shown by Mr. James. It was a splendid one, large in spike and flower and richly coloured, and was appropriately named *grande*. Mr. G. F. Wilson, Heatherbank, Weybridge, showed a marvelously fine form of *Odontoglossum Andersonianum*, having large, long sepalled flowers, richly marked with chestnut-brown on a white ground. A specimen plant of *Lælia purpurata*, bearing twenty-two flowers on six spikes, was exhibited by Mr. Bones, gardener to Mrs. McIntosh, Havering Park, Romford. It was an exceptionally finely grown plant, and bore evidence of skilful culture, and a medal was deservedly awarded to Mr. Bones for it. Among other *Orchids* from Sir Trevor Lawrence were *Phalenopsis sumatrana purpurea*, a highly-coloured form of the type, the true *Odontoglossum Wilckeanum* and Toll's variety of *Miltonia spectabilis*, with large flowers of a delicate rose-pink. A cultural commendation was awarded to Mr. Clinkaberry, gardener to H. Hollington, Esq., Forty Hill, Enfield, for some plants of the lovely *Lælia majalis*, some of which bore uncommonly large flowers of a soft pinkish-mauve colour. The exhibitor evidently knows the requirements of this *Orchid*, judging by the plants he showed, for they were in perfect health, with large plump bulbs. Mr. Warner, Chelmsford, showed a wonderfully large and fine variety of *Masdevallia Harryana* under the name of *Distigniflora*. The colour was a brilliant magenta.

Rhododendron devoniense, a new seedling variety from Messrs. Lucombe, Pince, and Co., Exeter, was a beautiful plant, having large white flowers suffused with pink. It is one of the greenhouse section. Mr. Parr, Givon's Grove, Leatherhead, sent a *Carnation* named *Acme*. The flowers were large and of a beautiful deep rose. Mr. Graham, Cranford, sent plants and cut flowers of his fine new yellow *Wallflower*, named *Cranford Beauty*. *Pansies* in variety came from Mr. Eckford, Boreatton Park, Baschurch, and Mr. Divers, Maidstone, and *Primroses* and *Polyanthuses* were shown by Mr. Lowe, Chepstow, which included some pretty varieties. An uncommonly fine yellow *Polyanthus* was shown by Mr. G. F. Wilson, which was quite unlike any ordinary variety. A group of decorative plants tastefully arranged, and also some elegant stands of flowers, were contributed by Mr. Aldous, florist, Gloucester Road, to whom a bronze Banksian medal was awarded.

A group of novelties from Mr. R. Dean was interesting. It contained, besides the plants certificated, a variety of *Myosotis dissitiflora* named *Perfection*. It differs from the ordinary form of this beautiful *Forget-me-not* in the flowers being larger and of a brighter colour, and altogether finer. Among the others were a dwarf yellow *Wallflower* selected from the *Belvoir Castle* variety and apparently an improvement upon it; a new plant for carpet bedding named *Spergula pilifera aurea* with golden turfy tufts, and several fine show and self *Auriculas*, but the best plant in the group we thought was *Iberis gibraltarica hybrida*, which is unquestionably a valuable new plant. It is said to be a cross between *I. gibraltarica* and *I. Tenoreana*, and its appearance justifies the statement. It is dwarfer than *I. Tenoreana*, but more vigorous than that species. The large flat flower-heads are of

various shades of violet purple, very delicate and pretty. The plants shown were uncommonly well flowered, and were perfect specimens of good culture. It surely ought to have been considered worthy of a certificate.

FRUITS AND VEGETABLES were not numerous. An extensive collection of varieties of *Rhubarb* was sent from the Society's garden at Chiswick, and which comprised all the known sorts, some being, to all appearance, alike. Stott's *Monarch* and *Victoria* were the largest, and the other sorts included Johnson's *St. Martin*, Dancer's *Early Red*, *Defiance*, *Crimson Perfection*, and *Champagne*—all with useful sized leaf-stalks. A cultural commendation was awarded to Mr. Allan, gardener to Lord Suffield, Gunton Park, Norwich, for four fruits of *Hero of Lockinge Melon*, which, having regard to the early date, were exceptionally fine and well coloured; one in particular was very large and finely netted, and weighed 3 lbs. 15 ounces. A cultural commendation was also awarded to Mr. Stevens, gardener to the Duke of Sutherland, Trentham, for two dishes of *Cherries*, excellent for the season. Messrs. Carter & Co. sent a dish of their new *Golden Queen* or *Como Onion*, a small sort and a very useful size for some purposes. Mr. Todman, Tooting Common, sent a dish of his new *Early Prolific French Bean*. It was referred to Chiswick for trial. Two uncommonly fine brances of a new *Cucumber* were exhibited by Messrs. Sutton & Sons, Reading. It was named *Defiance*, and was stated to be a cross between the *Blue Gown* and *Kirklees Hall* varieties. The fruits were large, long, and smooth. First-class certificates were awarded to

PEACH ALEXANDRA.—A new and very early variety, with medium-sized and highly-coloured fruits, said to be of excellent quality. Exhibited by Messrs. Rivers, Sawbridgeworth.

SPINACH MONSTRUEUX DE VIROFLAY.—A fine variety with large leaves, said to be of excellent quality, and a rapid and vigorous grower. Exhibited by Mr. Barron from the Society's gardens at Chiswick.

The committees were constituted as follows: *Fruit*.—Mr. H. Veitch (chairman), Messrs. J. Lee, L. Killick, G. Bunyard, J. Smith, P. Crowley, F. Rivers, and Dr. Hogg. *Floral*.—Mr. G. F. Wilson (chairman), Messrs. W. Bealby, J. Wills, J. Laing, S. Hibberd, H. Bennett, G. Duffield, H. Turner, H. Ballantine, J. Dornay, H. Ebbage, J. Hudson, H. Cannell, W. B. Kellock, and T. Moore.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair.

Pinus Nordmanniana diseased.—Mr. MacLachlan gave his report on this specimen sent to the last meeting by Mr. Noble, and considered the insect to be *Chermes corticalis* in a young state, but he required to see the winged form before speaking positively. He recommended the means used in America for destroying orange scale, &c. The most effective appears to be an emulsion, of which the recipe is as follows: Two parts refined kerosene and one part of sour cow's milk; apply as spray by means of a force pump. It must be used at once while the oil and milk are intimately mixed. Or a solution of 1 pound of whale oil soap with 1 gallon of water. Apply as spray while hot, because it solidifies on cooling. Mr. Noble sent a group which had been treated as above. It certainly had done no damage to the tree, but Mr. MacLachlan could not say for certain whether the eggs had been killed, and recommended a second application as soon as a new brood appears.

Orange Coccus.—Sir J. D. Hooker showed specimens with a letter from Mr. G. S. Jenmann, of the Botanic Gardens, Georgetown, British Guiana, asking for information as to the best method of destroying them. It was referred to Mr. MacLachlan for report.

Primulas.—Dr. Hogg observed that he had raised the English *Oxlip* from seed and it had come perfectly true. He also raised a seedling of the *Bardfield Oxlip*. This, however, developed into a *Polyanthus* of a dull red colour, but with all the characteristics of form of the English *Oxlip*. Mr. G. F. Wilson exhibited a fine *Polyanthus* of a mauve tint, having a greenish centre.

Ixiolirions.—Mr. Elwes exhibited sprays of three species—*montanum*, *Ledebourianum*, and *tataricum*, which under cultivation appear to be very nearly identical.

Tulipa undulatifolia.—He exhibited a cultivated specimen to show how it had changed from the wild state, as it occurs in Asia Minor. The wild form has the edge of the leaf closely crimped, the leaf is linear, and the flowers one-third the size of the cultivated plant; whereas the leaf shown was broad with a waved margin.

Fritillaries.—He also exhibited flowers from the supposed species *pyrenaica*, *lilacea*, *oranensis*, and *lusitanica*, with a small dark coloured as well as a yellowish-green-flowered seedling. All these Mr. Elwes is inclined to think identical, though *F. bithynica*, with green flowers and four large bracts, seems very distinct. The question was raised whether the above could not be the result of hybridisation. Mr. Elwes remarked that Lilies were, and he thence inferred the *Fritillaries* would be very difficult to hybridise. Hybrid Lilies always died out very soon.

Iris hybrid.—Professor M. Foster exhibited a hybrid between *I. balkana* and *I. Cengiali*, with probably some of *I. pallida* in it. The former has purple and veined flowers, *pallida* being sky-blue. The hybrid had the foliage, scape, and spathe of *balkana*, but the stamens of *pallida*, while the flower was much larger than in *balkana*. He remarked upon the great difficulty of *Iris*es setting seed unless artificially crossed. Bees appear to be very inefficient agents. Mr. Elwes remarked that lowness of temperature had often much to do with the setting of seed; especially is the case with Tulips, and observed that they did so with greater freedom in the Mediterranean regions than with us. This was corroborated by Sir J. D. Hooker, who remarked that a relatively small number of plants at Kew seeded well as compared with the great number grown. Dr. Hogg remarked that florists grow a great many whole coloured Tulips as "breeders," and wait, it may be, ten years before they "break," and that conversely if variegated Tulips are not taken up, they revert to self. Mr. Henslow remarked that the facility of raising seed from whole coloured flowers was co-related with the fact that such (as Mr. Darwin had them) are much better able to fertilise themselves. With reference to the varieties of colour, Dr. Masters observed that a plant of the common wood *Anemone* transplanted to a garden has now turned blue. Mr. Elwes remarked that at Bangor four colours occur in the same wood.

Lilium Thomsonianum.—Mr. G. F. Wilson brought a cut spray. The plant has ten spikes, the main one has thirty-five flowers on. It is very difficult to blossom unless the bulbils are all removed.

LECTURE.—The Rev. George Henslow took the *Narcissus* as the subject of his lecture, which was illustrated by many specimens from Mr. Barr's beautiful collection. With reference to the origin of the name, he explained how in Greek mythology the son of Cephissus and Liriope, slighting the Nymph Echo, fell so desperately in love with his own shadow in the stream instead, that death alone could release him from the anguish of unrequited love. The Naiads mourned for him, and on searching for his body discovered nothing but a beautiful flower instead, which henceforth bore his name. Coming to more prosaic matters, the genus, though abounding in "forms," is, according to Mr. G. Baker, a limited one. That botanist groups them under three heads, viz., those with long trumpet-shaped crowns or "coronas," as the Daffodils; those with crowns of a medium length, as in the imperialis group; and those with a mere rim, as the Poet's *Narcissus*.

Describing the structure of the flower, he pointed out the difference between the family *Amaryllidee*, to which the genus belongs, and that of Lilies, the former being known by all its members having the "ovary" below the perianth. The crown he explained as being a mere out-growth from the perianth, and would seem to correspond to the rim seen in the corollas of the Primrose and

Forget-me-not. It is not at all characteristic of the majority of the genera in the family, the *Amaryllis* and *Snowdrop* being entirely without it. Double flowers are frequent and are of different kinds: 1, the corona may be filled with a mass of petals; 2, the perianth and corona may be broken up and repeated many times, so as to form an irregular mass of petals; 3, the petals may be piled up in front of one another, as in a Rose; this occurs in the var. *cystettensis*. With reference to physiological properties, the *Narcissus* is more or less poisonous, the Daffodil and the Poet's being especially so, and have been used in medicine as emetics. Other members of the family are poisonous, as *Brunsvigia toxicaria*, which is used by the natives of South Africa to poison fish. It was this which accidentally poisoned Dr. Pattison, though he fortunately recovered. The *Narcissus* has been long cultivated in England. Gerard in his "Herbal," A.D. 1597, describes seventeen kinds, and Parkinson in his "Paradisus" (1629) figures a good many and describes ninety-two kinds.

Selecting a few for illustration, Mr. Henslow first alluded to the Hoop-petticoat, *N. Bulbocodium*, from the western Mediterranean regions, and which is remarkable for the shape of the crown and the delicate stamens. It is recorded that a bulb of this species having been in a herbarium for twenty years, subsequently revived, was planted and flowered.

The Daffodil or *N. Pseudo-Narcissus* is probably the only native species of Great Britain, though the Poet's *Narcissus* is naturalised. It is very variable, especially under cultivation. The size of the flowers quite justifies the terms *maximus*, *major*, *minor*, *minimus*, applied to as many varieties. The colour may be all yellow or the perianth white, while the crown alone is yellow (*eg. bicolor*) or all white (*eg. cernuus*), such as are the Spanish forms.

Double forms of the larger sorts are common, though that of the true wild Daffodil is not.

Of the second group, with shorter crowns, the most important is the form *incomparabilis*, with its many varieties. This is now considered to be a hybrid between the Poet's *Narcissus* and the Daffodil, although it occurs wild in France and Spain, for Dean Herbert and others have raised it from such a cross. Indeed, he thought that by using the pollen of *N. poeticus* successively for two or three generations the Daffodil could be converted into *N. poeticus*. It is remarkable that the purple of the cup of *N. poeticus* with the golden yellow of the Daffodil give rise to an orange tint in the cup of *incomparabilis*, just as a purple and chrome yellow mixed on a palette produce a similar orange. Another important species is *N. odoratus* (the "Campanelle"), of a pure yellow colour, with a six-lobed corona, and is very scented. This is intermediate between the Jonquil and *incomparabilis*. Its native home is Southern France, Italy, to Dalmatia.

Of the third or short-crowned section *N. Tazetta* is, perhaps, the most variable; the Dutch, even in 1800, cultivated as many as 300 forms. It has apparently the widest geographical range, for if not truly wild there, it is, at least, very largely cultivated in China. All other species appear to be limited between England and the Caucasus. It is the common *Polyanthus Narcissus*, as it bears many flowers on the scape. The typical form has a white perianth and a yellow cup, but varies in colour like the Daffodils, and may be double as well.

The true *Narcissus* of the ancient poets appears to be *N. poeticus* or *biflorus*, especially the former, as it is described by Virgil as "purpureus," doubtless in allusion to the purple rim to the crown, which colour is wanting in *N. biflorus*. Its double form, resembling *Gardenia florida*, is much cultivated for decorative purposes.

EVENING MEETING.—The first evening meeting in connection with the new scheme of this Society was held in the Linnean Society's rooms, Burlington House, on Tuesday last. In every sense this first meeting must be regarded as an unqualified success. There was a numerous and influential

attendance, and the promoters of the movement provided for it ample entertainment, there being an extensive and beautiful display of choice and interesting plants and flowers, and the papers read were of a highly interesting character.

Lord Aberdare presided. In his opening remarks he alluded to the vicissitudes the Society has experienced since the old days at Chiswick and since it had made South Kensington its headquarters. He regarded these evening meetings in the light of a "new departure" calculated to extend the sphere of usefulness of the Society both in a scientific and practical sense. The Society, now almost elbowed out of South Kensington, will, it is to be hoped, ere long be in a position to acquire a home of its own in some central situation in London, where it would be enabled to hold its meetings and small choice exhibitions. That established, we think its future could not fail to be both a bright and a useful one as regards the advancement of horticulture.

The papers read on this occasion were as follows:—

"*Iris susiana* and its Allies: their Habitats and Culture." By Dr. Michael Foster, F.R.S.

"Australian Apples." By Dr. Hogg.

"Hardy Cacti: their Habitats and Culture." By Mr. E. G. Loder.

"Novelties in the garden at Baden-Baden." By Herr Max Leichtlin.

A paper on "Cypripediums," by Mr. W. Goldring, was, for want of time, deferred until the 12th of June, the date of the next evening meeting.

IRIS SUSIANA AND ITS ALLIES formed the subject of the first paper by Dr. Michael Foster, than whom no one better qualified to speak on *Iris*es could be found, as he has made them a subject of special study. He explained in the first place the structure of the flowers of *Iris*es, generally and particularly of the group *Oncocyclus*, to which the *Susian Iris* belongs. He then dwelt at some length on the organs of the flower which had special relation to fertilisation by insect agency, and illustrated his remarks by numerous diagrams and sketches. He then referred to the early history of the *Susian Iris*, how it took its name from Susa, in Persia; how it had been the object of much interest to such early botanists as Clusius, and also to the manner in which it had found its way into cultivation in this country, through Holland, in the latter half of the sixteenth century. The allied species of *I. susiana* were then commented on. These, he said, were *I. iberica*, the commonest of the group in gardens at the present time, and of which he had about a score of fine flowers before him; *I. Heylandiana*, a very beautiful species recently discovered in Mesopotamia; *I. Saari* and its variety *lurida*, both in the way of *I. susiana*, and both in cultivation in this country; *I. acutiloba*, a beautiful Transcaucasian plant; *I. paradoxa*, one of the most beautiful of all *Iris*es, coming from Iberia, Armenia, and Persia; and a newly discovered species, *I. Krokowi*. These comprised the *Oncocyclus*, or *Susian Iris* group, and all bore large and very handsome flowers. The geographical distribution of this group was the next subject dealt with by the lecturer, who had charts of the geographical area over which the various species were dispersed. The headquarters of the group, he observed, were Palestine, Persia, Cilicia, and outlying members were found on hillsides in the surrounding districts. The native habitats of the plants and the conditions under which they grew formed an interesting subject, as it had a direct bearing upon the course of treatment which the plants required when under cultivation. Their culture, Dr. Foster observed, was somewhat difficult, as our climate is so unlike that of their native habitats. They require more sun than we have in this country; therefore in order to ensure success, recourse must be had to artificial treatment; the plants must be assisted in ripening their growths by placing them under glass in summer and by planting them in the open again in the autumn. The rains of autumn and winter do not injure them if the growths of the previous season were thoroughly ripened. An interesting

discussion followed Dr. Foster's discourse, in which Mr. Elwes and Mr. Baker took part. The former briefly alluded to the culture of Irises belonging to the Susian group just described, while Mr. Baker alluded to two other Irises of the group, namely, *I. Lorteti* and *I. Helene*, both of which have been rather recently discovered by Mr. Barbey in the Orient and described in Boissier's *Flora Orientalis*.

AUSTRALIAN APPLES.—Dr. Hogg gave a short account of some Apples which he had received from Australia. They had been sent from Melbourne in February last, and arrived in London in April. He remarked that American Apples now sent to our markets in such large quantities came to us when we had plenty of our own; but that here we had Apples which ripened at an entirely different time of the year, and which, it was evident from the sample produced, could be sent to us in good condition just when we most wanted them. Apple trees, he said, were being largely planted in Australia, hundreds of acres being occupied with them in Victoria alone, and he predicted that ere long their fruit would form a valuable part of Australian exports to this country.

HARDY CACTI was the subject of a paper by Mr. E. G. Loder, who makes this interesting class of plants a speciality in his garden at Weedon, in Northamptonshire, and who has recently collected them from their native habitats in Colorado and in other parts of North America. Many interesting facts were stated with regard to the native habitats of these plants, which are of so much value to cultivators. He illustrated his remarks by numerous diagrams, photographs, and pictures, but he was unable to exhibit any flowering specimens of hardy Cacti at this early season of the year. The subject matter of this paper was much the same as that on hardy Cacti communicated by Mr. Loder to *THE GARDEN*, Vol. XX., p. 601, Vol. XIX., p. 593, and Vol. XXI., p. 28.

Mr. Max Leichtlin showed flowers of a new *Bomarea*, collected in Peru by Lehmann. Flowers of a red *Aubrietia*, raised by repeated sowings in the garden at Baden-Baden. The colours, however, can only be properly judged when a mass is seen in the open. Flowers of a new *Saxifraga* named *speciosa*, a natural hybrid between the form of *S. Stracheyi* and *S. cordifolia purpurea*. It combines the size and fine shaped outlines of the flower of *Stracheyi* with the rose colour of those of *cordifolia*; besides it is hardy and very robust in constitution. A third of a leaf of *Trillium discolor* (Wray), dark olive-green, chequered by splashes of whitish green; the triple or rather whole leaf measures 9 inches across. A flower of *Veronica Lavandiana*, from New Zealand, dwarf and hardy.

The library of the Linnean Society on this occasion was gay with a bright display of plants and flowers contributed from numerous gardens. A glorious gathering of choice Orchid flowers from Sir Trevor Lawrence's garden at Burford Lodge, Dorking, was a great attraction, for rarely can such a display of Orchids be seen. It consisted of gorgeous *Cattleyas* (chiefly of *Mossiae*), *Lælia purpurata* and its variety *alba*, long, elegant wreaths of *Odontoglossums*, graceful sprays of brilliant-toned *Masdevallias*, while among the curious kinds we noted a fine spike of *Coryanthes eximia*, one of the rarest and most singular of all cultivated Orchids. Mr. Lee, of Downside, Leatherhead, also sent a rich display of Orchid blooms, chiefly of *Cattleyas*, *Odontoglossums*, *Vandas*, and quite a sheaf of *Masdevallia Harryana* and others. Another beautiful feature was an extensive display of *Rhododendrons*, from Mr. Mangles, of Valewood, Haslemere, who makes a speciality of *Rhododendrons*. These included huge trusses of *R. Nuttallianum*, one of the largest flowered of all the species, and with splendid white blossoms. In contrast with this was a flower spray of the tiny white *R. anthopogon*, one of the smallest of *Rhododendrons*. The group also comprised a large gathering of trusses of seedling and hybrid varieties, chiefly of the high coloured arboreum type. Mr. Major, of Croydon, and Mr. Boscawen also exhibited *Rho-*

dodendrons. Mr. Loder, of Floore, Weedon, contributed a most interesting collection of hardy plants, including rare and beautiful species, and a similarly interesting group was exhibited by Mr. Lynch from the Cambridge Botanic Garden, among which were *Cheiranthus mutabilis*, flowers of *Aloe plicatilis*, *Arctotis Aureola*, a handsome composite, *Siphocampylus bicolor*, *Vitis gongyloides*, *Nicotiana affinis*, the night-scented Tobacco plant, *Saxifraga peltata*, and *Pyrus spectabilis*. Messrs. Veitch contributed a choice group of plants, chiefly of *Nepenthes*, *Sarracenia*, the elegant *Asparagus plumosus*, and *Anthurium Scherzerianum*. Mr. B. S. Williams sent plants of various species of *Cypripedium*, and Messrs. Barr had an attractive group of their beautiful hybrid and other *Narcissi*. In the lecture room was an extensive collection of cut flowers of *Cypripedium*, to illustrate the paper on *Cypripediums*, kindly sent by Sir Trevor Lawrence, Messrs. Lee, Bowring, Peacock, and also flowers of hybrid varieties from Messrs. Veitch.

Lawn mowers.—I accept the challenge (p. 415) on the conditions named by Mr. May, Walton-on-Thames, if he will allow the further proviso named by me in *THE GARDEN* (p. 370), viz., that the lawn mower he uses at the proposed trial is to "satisfactorily cut" grass 5 inches above the level of the knife-plate; and by "satisfactorily" I mean that the machine must cut it close, smooth, and even the first time over. I am aware long grass can be cut by raising and lowering the knives, and going over the ground two or three times. But that is not what I mean or what is understood. The general level of the top of the grass to be cut must be 5 inches above the knife-plate, and Mr. May must work the machine himself. I will endeavour to meet his arrangements to his satisfaction, and I promise to report the result truthfully and accurately. I shall be pleased to discover a mower that will do what he says. I have found none yet that would do it, not even the invincible, which, I observe, beat the *Excelsior* at Manchester in cutting long grass by three points to one. I observe that Mr. May has raised his boy's age three years since April 21, when a twelve-year-old boy could easily use a 14-inch *Excelsior* on any ordinary lawn. Now he is to be fifteen years, and it is stipulated that he is only to work it for "a reasonable time without undue fatigue." I must protest against any further extension. When Mr. May has intimated in *THE GARDEN* his acceptance of these conditions, as stated here, I will write to him privately and arrange matters to our mutual satisfaction.—AN OLD LAWN MOWER.

—In reference to the discussion on lawn mowers, allow us to say that we have several in daily use and work them for profit; consequently we naturally try to procure the most durable, efficient, and lightest working machines in the market. After trying nearly all that have been brought to our notice, we have come to the conclusion that for our constant hard work, for long or short, wet or dry Grass, there is no lawn mower in this country equal to the "Archimedeum." Luke Mr. May, we are neither lawn mower makers nor agents; but, unlike him, we have yet to see a lawn mower that will satisfactorily cut Grass 6 inches long on a thick English lawn. We have strong objections to imported lawn mowers, on account of the difficulty there is in obtaining broken parts or getting repairs done; but the "Archimedeum," although an American invention, is made in London, and in its case we have always been able to get done promptly what we required.—W. NORTH & SON, *Manor Lane, Lee, Kent*.

The "Standard" on lawn mowers.—He (the villa gardener) is, however, not without labour. He has a green patch of Grass, and after having in a man to mow this once or twice, concludes to try a mowing machine. Of course he requires one of the smallest size, one described by the maker as of "child" power. From the first he wonders over the strength of children, and finds that the machine requires all the power and much more than the average patience of a man. It is always clogging up or getting out of order. It

either does not cut at all, or tears the Grass up by the roots. After using it for a time he suggests to his wife that it will provide her with healthy exercise, but his wife altogether ignores the proposal. He then puts it to the servants whether it would not be a pleasant amusement of an evening for them to mow the Grass, but the servants both reply that they are not fond of gardening. The enthusiast, therefore—if he is not an enthusiast he will have given up the garden in despair at the end of the first year—is driven to work it himself. In time he gets to know the capabilities of his garden and enjoys them. It is not what he had dreamed of, but it is nevertheless pleasant. For labour a gardener comes in and digs the garden up thoroughly, when he puts in the *Chrysanthemums* and the bulbs, and during the rest of the year he comes in once a week for two hours in the evening to mow the Grass and tidy up.

Loudon's Arboretum Britannicum.—This work, with its illustrations, has been acquired by Mr. W. Robinson. The pages are not stereotyped, as are those of the "Encyclopædia of Trees and Shrubs," which is an abridgment of the "Arboretum." Of the "Encyclopædia" a small edition will be published by Messrs. Warne, after which the plates will be broken up, leaving the ground then free for a really new and complete work on the trees and shrubs of northern and temperate climes, should the taste of the public seem to warrant its production.

Grubs (W. J. W.).—The grubs you have sent are commonly known by the name of leather jackets. They were hatched from eggs laid by the daddy-longlegs, or crane fly. They are exceedingly destructive to many plants, and are very difficult to destroy, as any insecticide which would influence them below the surface would kill the plants. Numbers may be killed by rolling the ground at night. Long trenches 6 inches wide and 6 inches deep with upright sides have been found very useful; the grubs fall in whilst roaming about at night, and cannot escape. They should be collected in the morning. Pieces of Potatoes, Turnips, &c., buried in the ground, with a skewer stuck into each, form good traps; they should be examined every morning. Dressing ground with nitrate of soda, gaslime, soot, and guano has been found useful. When a plant is attacked, open the ground round the roots and pick out the grubs; they prefer damp, undrained land; moles and many birds are very fond of them.—G. S. S.

APPOINTMENTS FOR THE WEEK.

Manchester.—Whitsun week exhibition of Royal Botanic Society.

May 16.—Regent's Park.—First Summer Show of Royal Botanic Society.

Vanda teres Andersoni.—We have here a mass of this beautiful *Vanda* bearing fifty flowers; it flowers regularly every year, each spike having six or seven flowers on it, a sight worth seeing.—J. GILLIES, *Grovesea, Middlesborough*.

Azolla pinnata.—It may be interesting to some to learn that this little aquatic plant has lived in the open garden frozen in 12° of frost in one of the tanks here provided for various kinds of aquatic plants quite exposed.—CHARLES GREEN, *Pendell Court, Eatchingley*.

BOOKS RECEIVED.

"This is an Art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

AN INTERESTING SMALL GARDEN.

THE garden I propose to describe is one where the owner (like many others), for uniformity's sake, is forced to conform to an unnatural style of gardening instead of to the seemingly careless, wild, informal style so much more to the taste of all who love Nature unadorned. It is on a terrace on which the previous occupants, with exemplary unanimity, committed themselves to Grass plots, Grass slopes, and Grass edgings; with flower beds in every variety of geometrical design—circular, star-shaped, oval, and so on; indeed the aim seems to have been not to have two alike. This style, however, had to be accepted, or the neighbours would have complained that the regularity of their lawns was spoilt by an adjoining wilderness. Still, much has been done to render this primness nugatory by ousting out all notions of annual bedding and planting perennials. Commencing with a selection of the most irregular stones to be found in an adjoining quarry, preference being given to such as were moss-grown, and half burying them, a natural appearance of outcropping boulders was obtained, and a few plants of the evergreen Iberis, Saxifrages, Sedums, and Mosses soon hid any faulty junctions between soil and stone. In a space of 50 yards by 20 yards much cannot be expected where the bulk is already appropriated by Grass, with its too great preponderance of bright green for colour harmony, but two borders at least are worth notice; one running the entire length of the garden is 50 yards long by 3 yards wide; the other at the end of the garden measured 20 yards by 4 yards, the latter unfortunately shaded by Balsam Poplars. Along this lesser border the path is irregularly edged with stones of all shapes, in the shelter of which Primroses, Polyanthes, and Auriculas are planted; and as these get the benefit of plenty of light in spring before the overshadowing trees have come into leaf, they luxuriate, teaching us that many spring flowers may be well grown in what turn out a few months hence to be moist, shady situations. Under the trees, Daffodils, Wood Anemones, Ferns, and Foxgloves from the adjacent woods fill up what is generally a hiatus, whilst in the three divisions formed by paths, still shaded from the south, are British Orchids, patches of Mimulus, Mosses, shade-loving alpine, and such plants as Cyclamens, Camassia esculenta, Anemone fulgens, A. Helena Maria, Winter Aconite, Dog's-tooth Violets, mixed Oxalis, Irises, and Arums, not forgetting the Christmas Rose; these are backed up by Lupines, Fumitories, Lavender, and Sage. The larger border of the two, running north and south and "sloping slowly to the west," is, however, that which affords the most pleasure, for here may be seen blooms of some kind all the year round. An ugly wall is hidden by Hollies, the red-flowered and white Ribes, and Laurels, these being so disposed that even in the depth of winter a comforting bit of colour is furnished for the artistic eye to rest on.

The ends of this belt of shrubs are left open, the side entrances being filled up with plants of the trailing Rosa arvensis of the woods and Sweet Brier. In front of the shrubs Lilies are grown—

L. tigrinum and *bulbiferum* alternating with clumps of *L. auratum*, a few Sunflowers and single Dahlias being interposed; then come *Chrysanthemums* (Pompone varieties), *Gladioli*, *Tigridias*, *Aquilegias*, perennial *Phloxes*, and *Sweet Williams*. Before these again comes (I am sorry to say it) a row of twenty-five budded Briers of last season, the maiden blooms of which are expected to create a sensation, and to hide the long, ugly legs of these half-standards dwarfs on the *Manetti* are planted, and the *Roses* in turn are fronted by *Narcissi*, *Daffodils*, *Tulips*, *Anemones*, *Monardas*, *Pulmonarias*, *Funkias*, *Chionodoxas*, and *Snowdrops*, whilst the very front rank is occupied the entire length of the border by fancy *Pansies*. These *Pansies*, which were shrouded for six months of the winter under a blanket of dead Bracken and tanned matting, were uncovered during the mild weather of early March, and looked like bunches of *Watercress*, so fresh and green were they; but the 9th of March sadly injured them, with the exception of old stagers, such as *John Currie*, *John Grainger*, *Buttercup*, and *Fred. Perkins*, and these with their progeny of rooted cuttings in a circle round them have sufficed to fill up the blanks made in the ranks. But for this one frost the *Pansy* border would have been 2 feet wide, all grown from single plants put in last spring. The best way in which to increase a border of this kind is to open or lay bare the centre of each plant and drop on it a handful of sand and leaf mould in equal parts; in this the young shoots always springing from the centre readily root, and in a few weeks may be easily, but gently torn out and transplanted. These young plants give the largest blooms and best markings, whereas the old plants deteriorate. We may thus maintain individuality and perpetual rejuvenescence without much trouble. For winter protection, as has been stated, fronds of dead Bracken are laid lightly over all on the first frost setting in, and these in turn are covered with a strip of old netting to keep them from being blown away. Under this covering *Pansies* are many degrees warmer than they would otherwise be and scarcely cease growth all winter. Indeed, the only thing to guard against is too early uncovering.

On the other side of this small garden a dividing fence of iron hurdles is utilised by having galvanised wire netting fastened to it, and on this such climbing *Roses* as the *Evergreen Félicité Perpétue* and *Dundee Rambler* are trained, each being budded in the case of a few shoots with *Hybrid Perpetuals*. *Sweet Peas*, major *Nasturtiums*, *Hop-bines*, major *Convolvulus*, and *Canary Creepers* are allowed to ramble as they please over this wire-work. Next come four beds—round, oval, star-shaped, and nondescript, the first being filled to overflowing with *Carnations*, *Picotees*, and *Pinks*, not forgetting the old crimson *Clove* and the white *Mrs. Sinkins*. Bed No. 2 contains *Roses* on the *Manetti*, but treated in an uncommon, though not a new way. A tall shoot near the centre of each plant is left erect, a few inches being cut off the extremity in pruning, and all buds but four or five of the uppermost are rubbed off as they appear; the rest of the branches are bent to the ground, slit with a knife for half an inch in length at the point where they touch the soil; there they are fastened to a slight stake, and a mixture of leaf mould and sand is put round the fracture, care being taken not to break the bark all round. This gives us from one plant (a standard) a bed of *Roses* close to the ground, and

on their own roots. The third bed is occupied by dwarf *Roses*, *Moss*, *Damask*, *China*, and *Hybrid Perpetuals*, with clumps of *Irises* in the intermediate spaces, whilst the last bed contains own-root *Roses*, interspersed with masses of *French Ranunculuses* and *Myosotis*. *Roses Madame Berard* and *Gloire de Dijon* ornament the house front.

Horsforth, near Leeds.

R. A. H. G.

NOTES.

THE CRESTED IRIS is not too common in the best of gardens, albeit very lovely when its delicate mauve blossoms peep up thickly among its short, broad spear-like leaves. A mat-like mass of this dainty crested *Iris* now lies in the sun before me bearing a hundred or more of its flowers and purple-tipped buds, the whole mass, fresh leaves and flowers, nestling quite close to the earth, being in this way more dwarf than the *S. pumila* varieties, and bearing flowers of different structure. In warm, moist, sandy soils this beautiful *Iris cristata* spreads so quickly, that one wonders the more at its rarity in most gardens.

THE GRAPE HYACINTHS are all very lovely. How rarely, however, is the true *Muscari pallens* to be seen. It is similar to the white form of *M. botryoides*, sometimes called by old authors "Pearls of Spain," but is dwarfer and of a delicate pearly grey or lilac hue. The varieties and shades of blue to be found among blue Grape Hyacinths are so marked and different, that I expect *M. botryoides* to be a species of extended distribution, and therefore climate and natural seedling have done good work in adding a variety of charm to its native beauty. These forms of Grape Hyacinth are, however, so commonly met with in all good old gardens, that we need say no more of them, but the yellow Musk-scented kinds are less frequently seen, and yet a few shrivelled flowers in a drop of water long remain a fountain of sweetness when brought indoors. This plant is *M. moschatum*, of which there are three or four kinds, the best of all and one of the rarest being *M. moschatum flavum*, which is just now in bloom. Its buds are purple when young, but turn soft, pure yellow as they attain their full size. The large waxy bells and their delicious fragrance are but too seldom to be appreciated; even in good nurseries it is a rare plant, but this rarity of itself will be to some a recommendation.

DIVERSITY OF COLOURS.—"About 15,000 varieties of colour are employed by the workers of mosaic in Rome, and there are fifty shades of each of these varieties, from the deepest to the palest, thus affording 750,000 tints, which the artist can distinguish with the greatest facility." So much for stone pictures, but who shall tell us of the myriad colours, and shades, and hues which lie ready to the hand of the gardener? Nature and art have given to him a palette and a canvas of the best, and it is his own fault if his work be not noble and enduring. It is his duty to make the earth "bring forth her increase" of blossom and nobler fruitage. He may paint the earth with loveliest colour, and drape rock, or wall, or tree trunk with the magic living tapestry of Nature herself. To no other artist has she given so much; none have been honoured as she hath delighted to honour him; all others may but copy or imitate her. At the best a "true likeness" is their reward, but he who would plant a modern Eden is alone permitted to enhance her own charms. "This is an art which does mend Nature: change it rather: but the art itself is Nature."

THE TIME OF WINDFLOWERS.—Some of the *Anemones* are just now very fine, all the *A. coronaria* and *A. stellata* varieties to wit, and a great blaze of colour, bright as Poppies, they make along with *Wallflowers* and *Tulips* in the balmy sunshine. But the gems of the tribe now in bloom are *A. alpina* and its still more lovely soft-yellow variety *A. sulphurea*, both now at their best, and

the last is as I take it perhaps the *Anemone* of spring-time, stately and refined in port and colour, while, its soft finely-cut foliage rivals that of *Thalictrum* or Fern. Tufted masses of *A. thalicroides* (some call it *Thalictrum anemonoides*) are now thickly beset with pure white stars, and the two double-flowered varieties of *A. nemorosa* are also in bloom, beside that most graceful of all the *Windflowers*, *A. sylvestris*, which is everywhere throwing up its pure white flowers towards the sun, while its downy buds hang *Snowdrop* fashion above the dark green tuft of leaves. Even the dwarf *A. decapetala* has a soft clear greenish yellow beauty of its own. Odd blooms of *A. apennina* still linger in moist, shady nooks, but the two loveliest of all early spring kinds, *A. blanda* and *A. nemorosa* var. *Robinsoniana* (*A. n. var. cœrulea*) are things of the past for this year. Some people have told me that *A. apennina* and *A. blanda* are merely forms of the same plant; but while the first has thick stringy roots, *A. blanda* has large corrugated tubers; indeed, when their underground growth is seen side by side no one could confound them.

*
THE BRONZE LEAF is a plant not often seen, allied to the *Saxifragas*, and a native of Japan. I saw it at Coombe Wood two years ago; it is one of Mr. Maries' introductions, and was considered valuable, for I could not get a bit of it either for love or money from Mr. Veitch, and yet when I narrated the fact to my friends the amateurs, two of them sent me nearly as much as would fill a wheelbarrow. The plant is a noble one, and is now very fine, spreading out its large five-lobed leaves in the sunshine, and in colour they are fine olive-green or bronze, quite different in port and formation from those of any other hardy foliaged plant I know. Planted in bold clumps near to golden *Plantain Lilies*, or nigh to the golden-leaved *Comfrey*, the bronzy hue is intensified and a very striking effect is produced. Those who admire noble foliage should make a note of this, one of the noblest of all the "Stone-breaker" family.

*
PLEASURE GROUNDS.—I sometimes wonder how far this name is truly and rightly applicable to the outlying portions of the lawn, since, as a matter of fact, every inch of a garden, however large or however small, ought to be a pleasure, or garden of pleasure to its proprietor. Whenever a garden or a portion thereof becomes a burden to dress and keep, there is something wrong, and the sooner the owner makes it pleasant to himself in some other way the better, for if a garden is worth the name it must yield either profit or pleasure or both in return for the work expended upon it. Would that our gardens were more often pleasure grounds than they are; and yet I know some few gardens that are well planned and so well planted that while yielding their owners much genuine enjoyment, they are not at all expensive to keep. I was in such a one yesterday. Sloping down to the sun a little lawn leaned towards a fruit and Cabbage garden, with a nook or two stolen here and there from the vegetable quarters for a few *Roses*, or for a few choice alpine collected by their owner in his own holiday tours. Here a *Rose* has wedded an *Arbor-vitæ*; there is a blaze of *Forget-me-nots* and *Tulips*; a few choice *Ferns* grow on the wet stones near a little water-tank, and just now the place is a picture of green turf and Apple blossom. Two or three little greenhouses nestle in the lower garden, where *Orchids*, *Ferns*, and other exotics thrive. They are mostly the willing gifts of friends of kindred tastes and fancies, and while in bloom they are brought to live in the dwelling-house, and so for the time become personal acquaintances rather than mere floral ornaments. In these greenhouses all space is utilised; floors, stages, walls, and roof are alike taxed to support as much floral beauty as may be, and some large flower-pots filled with water and used as tanks for aquatics of curious interest are fairly swaddled in a mat of the black hair-like roots, and bristling with fresh green fronds of the native *Maiden-hair Fern*. *Caladiums*, *Begonias*

Coleus, *Hoyas*, *Orchids*, *Ferns*, and *Selaginellas* all live together in happy company, and I am very much mistaken if there are not larger and more expensive gardens which yield far less enjoyment to their owners than does this small one to my friend. This and many other little gardens of similar kind are real pleasure grounds to those who have them, yielding something pleasant to the eye and also produce good for food.

VERONICA.

PLANTS IN FLOWER.

FRENCH ANEMONES from Colonel Stuart-Wortley's garden at Rosslyn House, Grove End Road, remind us that these brilliant spring flowers can be grown admirably even in a London garden. The rosette-like flowers are of various bright shades of scarlet, crimson, blue, purple, and are well developed. Colonel Wortley remarks that he finds them very useful in making the garden gay at this season.

ARBUTUS MILLERI.—I send you a spray of this *Arbutus* to show you the beauty of its clusters of almost pure white flowers. I find it quite as hardy, if not harder, than the common *Arbutus*, and you will notice that the flowers and foliage are more robust. I have not seen any fruit yet.—JOHN S. TREVOR, *Hampton House, Malvern*. [Evidently a handsome shrub, having vigorous foliage and large dense clusters of white Lily of the Valley-like flowers.]

THEROPOGON PALLIDUS is the name of a rather new and pretty greenhouse plant from the Himalayas. It may be best likened to an *Ophiopogon* in the foliage, which is long, narrow, and recurved, but the flowers are very similar to those of *Lily of the Valley*, and exactly the colour of what is known as the rosea variety. They are produced in spikes slightly overtopping the foliage, and their colour is a pale violet-purple. It is an easily grown plant treated in an ordinary greenhouse temperature, and when well grown has a pretty effect when in flower, as it now is at Mr. Bull's nursery at Chelsea.

THE ACACIAS in the temperate house at Kew are just now worth a journey to see, particularly the large planted out bushes of *A. armata*, verticillata, and others which are 8 feet or 10 feet high, and complete masses of yellow blossoms. Small pot plants on the stages represent a large number of species from which a selection of the best and most useful sorts for that kind of culture may be made. It is, however, when planted out in free soil and with plenty of room for development that *Acacias* are seen to best advantage, and where possible they should be so treated in private gardens.

MARECHAL NIEL ROSE.—Some glorious blooms of this popular favourite, figured in THE GARDEN last week, has reached us from Mr. Fyfe, gardener at Thames Ditton House, where it appears the *Maréchal* is grown to perfection. In the conservatory there a grand specimen has produced hundreds of blooms this season, and if of the same fine quality as those now sent us by Mr. Fyfe, it must indeed have been a beautiful sight. In some places the *Maréchal* is a capricious subject to cultivate, and on the other hand it seems to flourish to perfection in some gardens without any special attention. Mr. Fyfe could, perhaps, give our readers a few hints upon his course of treatment.

CALOCHORTUS LILACINUS.—A flower of this charming little Californian plant comes from Colonel Stuart-Wortley, who appears to be successful with its culture, as he says that "every bulb has thrown up three or four flowers which last a long time, and the one sent has been open seven days." *C. lilacinus* is one of the true *Calochorti*, that is those species having large, open, spreading flowers. It has rather broad leaves and conspicuous bracts, and bears its flowers on long, slender stalks, from four to eight from a bulb. The flowers measure nearly 3 inches across; the three broad petals are a pale lilac-mauve, blotched with purplish red at the base,

covered on the inner surface with short silky hairs. It is a native of California, about San Francisco, and was figured in the *Botanical Magazine*, t. 5804, under the name of *C. uniflorus*. It is, indeed, a pretty plant, and one well worth a little trouble in cultivating.

POLYANTHUSES.—Two correspondents, Mrs. Mansfield, Castle Wray, Ireland, and Mr. Horley, Toddington, Beds, send us some beautiful gatherings of *Polyanthuses*. Mrs. Mansfield contributes some extremely pretty sorts, good in flower and rich and varied in colouring. As she observes, they have great decorative value for the open garden, and the raising new seedlings of them affords much pleasure. Mr. Horley's are chiefly *Hose-in-hose* kinds, and are likewise very showy.

LATE CHRYSANTHEMUMS.—Having seen several accounts in THE GARDEN of late-flowering *Chrysanthemums* this season, I enclose blooms of a white Japanese variety, named Mrs. Charles Carey, cut from a plant that has been in bloom since November last. Last week thirty blooms were all open at once, and there are buds in all stages, so that this variety will be in bloom for a long time to come. Till last week I had another—an incurved variety—in bloom named *Exquisite*, but its beauty is now over.—E. PETERS, *Somerset Terrace, Guernsey*. [These unusually late blooms are really very fine, as large and as pure in colour as in November. Soon we shall be having *Chrysanthemums* all the year round.]

CRASSULA JASMINEA makes an extremely pretty pot plant for the conservatory at this season when grown as it is by some of the market growers around London who lately seem to have taken a particular fancy for it. It is very neat in growth, being only about 6 inches or 8 inches high; its dense tufts of flower-stems form a compact globular mass of white blossoms which at once remind one of *Jasmine*. It is a near relative of the well-known *Kalosanthes coccinea*, the flowers being about the same size and shape, and borne in similar umbelled clusters, but white instead of crimson. It is an old plant in gardens, but it is only recently that its merits as a market plant have been recognised. It is made free use of by Messrs. Veitch in furnishing their large conservatory in the Royal Exotic Nursery, Chelsea, at the present time.

Names of Poppies.—Last autumn, when looking over the Rev. Mr. Ewbank's garden at St. John's, Ryde, I was particularly struck with the gorgeous black-blotched crimson flowers of a dwarf *Poppy* which he informed me was *Papaver umbrosum*, and kindly gave me some seed, stating that the best way to treat it was not as an annual, but as a biennial. It should, he said, be sown in pans or boxes and wintered in a frame or cold house. Acting on this advice, I sowed the seed immediately on my return, and have now plants that promise to flower much earlier than spring-sown ones. As soon as I get expanded flowers I shall endeavour to verify the name. This *Poppy* is dwarf and compact with very pretty laciniated foliage.—JAMES GROOM, *Seafield, Gosport*.

Myosotis dissitiflora alba.—The prevailing idea respecting this lovely *Forget-me-not* at one time was that it was only the white variety of *Myosotis sylvestris*, but as I had an opportunity of seeing it in quantity frequently when living in Kent, I felt sure it would not be long before its true character and merits would be recognised. I am, therefore, pleased to see that Messrs. Veitch have taken it in hand. Good clumps of it in pots are strikingly beautiful, and can easily be had, as it is a plant which can be readily raised from seed. Seed-bearing plants must, however, be protected from linnets, or they will certainly take every seed as it ripens. I have frequently noted that even here, where birds are scarce, linnets find out the *Forget-me-not*, the seed of which they prefer to that of any other plant ripe at the same time. A small-meshed fish net is the best safeguard, and then any seed that falls on the soil will germinate; and this variety may even be readily increased by cuttings, or pieces of it merely pulled off and dibbled into any cool, shaded position will grow.—JAMES GROOM, *Seafield Nursery, Gosport*.

TREES AND SHRUBS.

EDWARDSIA GRANDIFLORA.

A WEEK or two ago some flowers of this valuable wall shrub were sent to us by Mr. Scrase-Dickins from his garden at Coolhurst, Horsham, and as the

species is one of the many plants discovered by Sir Joseph Banks in New Zealand, where it forms a tree of considerable size. A finer sight can scarcely be imagined than a tree of this sort extending to a great breadth on a wall with a western aspect in the apothecaries' garden at Chelsea, where it was planted by Mr. Forsyth about

otherwise, so as to induce it to form short-jointed shoots, which, if well ripened, will be sure to flower the succeeding season. There are several other species belonging to the genus *Edwardsia*, but we believe there is but one other in gardens besides *E. grandiflora*, viz., *E. microphylla*, which bears smaller and more slender foliage, and not such large and showy blossoms. This used to be grown against a wall at Kew, and though the plant rarely flowered, its elegant foliage had a pretty effect.

BERBERIS DARWINI AND JAPONICA

THESE are now in their glory, and when planted in suitable soils and positions, few of our early-flowering shrubs can surpass or even match them.

Both thrive best in good, rich loamy soil, thoroughly drained. They are very suitable for planting in the mixed shrubbery, as well as in plantations, where they afford excellent covert and food for pheasants. They also thrive remarkably well when planted on well-decomposed peat bog, especially *B. Darwini*, which often attains a large size, and produces great quantities of flowers and fruit. The latter, if protected from game with a piece of netting, falls to the ground when ripe, and produces a crop of seedling plants without any

trouble. Seedlings, however, whether self-sown or raised in a seed bed, should be planted into nursery lines when they attain a few inches in height, allowing plenty of room for development, and for weeding and keeping the ground in proper order. When one year in these lines, the stems should be cut over in spring a few inches above the surface of the ground; by this means they will produce three or four stems in the place of the one cut down, thus making fine bushy plants either for ornament or game covert. When intended for covert, they may either be mixed up with others, or planted in the form of groups of different shapes and sizes, each of which should be at distances of some 50 yards asunder. But, whether planted with others or in groups, care should be taken not to plant this *Berberis* in stiff clay soil, as it not only fails to grow, but often dies altogether in the course of a few years after planting. On patches of stiff clay, however, the *Berberis Aquifolium* grows freely, and, as it is a close bushy evergreen, it also makes excellent covert. I have likewise used *B. Darwini* in the formation of ornamental hedges, for which it is well suited; likewise for training on old walls and wooden fences where it is desirable to form a screen to shut out unsightly objects; and as it is a rapid grower and easily trained and kept in proper trim, it is admirably adapted for such purposes. The merits of *B. japonica*, either for covert or ornament, cannot be too highly appreciated. It is well adapted for planting as a single specimen on a well-kept lawn, and in such a situation it generally becomes well furnished and bushy; it may also be trained with a single stem in the form of a standard, which in spring produces pretty yellow flowers, surrounded by flat shining leaves, thus producing a striking contrast, which is in no way lessened when the flowers are shed, and their place filled up with pretty fruit, consisting of large berries of a bluish colour, covered with a bloom which cannot be surpassed, if even equalled, by that of the finest black Grapes. When it is desirable to propagate this species the berries should be protected by a piece of netting, in order to keep birds and game from eating them when they get ripe. My practice has been to sow the seed as soon as matured, choosing a piece of well pulverised ground in a sheltered place in the nursery for the purpose. It should be sown broadcast, and covered lightly with fine sandy soil, and in winter, should the weather be severe, the young plants will require a little protection, as they are liable to be cut down or thrown out of the ground altogether by hard frost. When

Flowering branch of Edwardsia grandiflora (flowers yellow). Sketched in April from a plant grown at Coolhurst, Horsham.

plant appears to be but little known, we thought that by giving an illustration of its flowers and leaves our readers would have a better idea of its appearance than words can convey. It is by no means new; it was indeed brought to this country from New Zealand upwards of a century ago, and formed the subject of a coloured illustration in the *Botanical Magazine* as far back as 1791. We therefore cannot do better than reproduce the note that appeared with this plate, which runs as follows: "This magnificent and highly curious

the year 1774, and which at this moment (April 28, 1791) is thickly covered with large pendulous branches of yellow, almost golden, flowers. They have a peculiar richness which it is impossible to represent in colour. In winter care is taken to cover it carefully with mats lest it should suffer from any extraordinary severe weather." A coloured representation of it appeared in *THE GARDEN* in 1877. Its chief requirements are a warm, sunny wall, protection from excessive cold in winter, and a good loamy soil, rather stiff than

they attain a height of 5 inches or 6 inches they should be planted out into nursery lines, allowing plenty of room for their development; and when they attain a height of 10 inches or 22 inches they may be planted out where they are to remain.

J. B. WEBSTER.

Cost of extinguishing forest rights in Epping Forest.—The extinction of the rights of fuel in the manor of Waltham Holy Cross and Sewardstone, which were utterly destructive to the appearance of the forest, cost £15,000, and £7000 were paid to the inhabitants of Loughton to extinguish their rights of lopping. The entire cost under the arbitration has been £109,505, besides £15,779 spent in improvements since October, 1882.

Deodar and Himalayan Silver Fir.—Most people will read with interest the following extract from a letter communicated to the *Indian Forester* by Mr. A. Smythies, from Messrs. James Backhouse & Son, York: "In reply to your inquiry, we believe that, in point of fact, there never was such a thing as what is usually called 'acclimatisation' anywhere. What has been done has been merely finding out what the constitution of each species, or variety, will bear in the way of climate. *Abies Webbiana* will not endure the casual (and especially late) frosts of low situations; but at an elevation of 500 feet or 600 feet, on well-drained hillsides, it grows very freely and forms a magnificent tree. Severe mid-winter frosts rarely injure it; perhaps we may venture to say never. The Deodar, so far as we have seen, always suffers severely, and often fatally, with a frost of great intensity, say thermometer at or below zero. In low ground therefore it is almost useless. At 500 feet it has a very good chance in many situations; 1000 feet is too high. Personally we should plant freely, and measurably fearlessly, both these conifers in the situations which we have just specialised. We think you will find as a rule that where natural hardiness is the result of high latitude there is nothing to fear, but that when supposed hardiness results from high altitude of native locality, the risk in all our low-lying ground is very considerable."

FLOWER GARDEN.

HARDY PLANTS IN YORKSHIRE.

NOTWITHSTANDING the severity of the weather and the lateness of the present spring, many plants are quite up to time as regards flowering, and never looked better, especially such as naturally push late. The *Gentians* have done well; *G. verna* has been in grand condition for a fortnight, and *G. acaulis* is fast coming on. The stout stems of the stronger growers are only a few inches high as yet, notably *G. affinis*, *G. Burseri*, and *G. lutea*; of the dwarf sorts, *G. ornata*, a free grower, *G. brachyphylla*, and *G. bavarica*, I may say that I find them, like *G. verna*, to do better in pots than elsewhere—at least they form more compact specimens. *Epigaea repens* is still in flower and has been so since early in March; it ploughs the loose surface leaf mould with its bloom spikes, which are half buried; it is very partial to shade. *Sanguinaria canadensis*, in a broad patch and well established in a moist part of a small rockery, has been exceedingly fine for a fortnight. *Viola biflora*, too, in large plantings, even if somewhat spare in foliage and small, has an effective appearance, its bright yellow flowers showing themselves off to advantage. It is a good rock plant, and increases moderately in leaf soil from self-sown seed. A score of bulbs of the *Belladonna Lily* planted exactly two years ago in the open at a depth of 9 inches are pushing satisfactorily; they were not of a first-class quality, the best having been taken for pot culture. Some of the finer varieties of tree *Carnation*, which I always winter in the open, are fresh and plump and just now making rapid growth. *Trilliums* never looked better with me, but what can have happened to the just opening flowers? They have a gnawed appearance, as if a strong-billed bird had been

picking them. We have had two distinct periods of *Hepatica* bloom; the first was checked by the March storm, and in mid-April the second came as a pleasant surprise. Now, the Apple-green foliage of the blue kinds, in bold patches, is truly effective; the leaves of *H. angulosa* are from 4 inches to 5 inches across. Tulips with heavy flowers are woeful objects just now, being broken off by the recent wind and rain. A neat belt-like tie slipped up the broad part of the leaves until all are slightly drawn together has not only saved a few in most exposed situations, but scarcely altered their natural appearance. *Hellebores*, nearly all of which were cut to the ground, leaves and flowers, in March, are again in fine condition, the leaves being well grown, some 15 inches or more high, and therefore very promising as regards next winter's flowers. The dwarf North American *Phloxes* have not got on so well; in fact many are killed; but I may add that where lime has been freely added to the soil they are all right. Irises do not seem to like my sunny situation and dry soil, and now that slugs are getting plentiful, they suffer a great deal from their ravages. It is only with much watching that small specimens of Irises can be established from one or both of these drawbacks. Just now *Narcissi* as a whole are at their best, all the sections being more or less represented. A patch of *Emperor* and *Empress* 3 feet across is a joy-giving sight, and tempts one to view it often; and how durable the flowers are! What a pleasant thing it is to find the roots of

CYPRIPIEDUM SPECTABILE as long and stout as those of plants gathered from their swampy habitats! This I found to be the case when taking up a few roots of *Primula rosea*, also grown successfully in the same compost. Many of the North American *Cypripeds* which had been nursed in pots and pans, and which had dwindled to the merest bits, were last summer turned out into the same quarters, where they have improved both in size and freshness. *C. acule* is now quite established in a sort of half boggy vegetable soil, rendered so by conducting the water to it from a walk. It has after three years passed its dwindling stage; the roots are now very active, and the crowns quite as plump as when imported. *C. Calceolus* has been established here in calcareous loam for several years, and I find it to be increasing, too, in some large pots plunged in very cool quarters during summer. When one recalls the pains taken to establish this interesting Orchid, and finds some roots simply buried in sand two years ago to have become the finest specimens about one's garden, all such efforts seem needless. The flowers from these were very fine last year, some being produced in pairs, and they seeded so well that I decided to leave them alone, though they were in a most inconvenient position. Baring the roots, new ones were found to be a foot long and very thick. They are also now showing finer foliage than before, and stouter than I ever saw plants from well-selected Swiss-grown roots. I consider that those wishing to establish this desirable *Lady's Slipper* may glean a hint here, and that it is not a mere chance hit in practice is proved by planting others in the same, or nearly the same, way from some potfuls which were not doing well, but which have freshened and grown well since.

EPIMEDIUMS.—About a dozen kinds were so badly cut in March, that there will be little or no bloom. *Viola pedata* and the bicolor variety seem to enjoy our climate. They are as free as the common *Pansy*. *Asarum caudatum* is an interesting plant. It is in all respects similar to the European species, except the flower, which reminds one of that of some of the tailed *Cypripediums*. Iris *Kämpferi*, strong seedlings of which were left out all winter for want of space under cover, have been badly damaged, many being killed. What a pretty plant is *Saxifraga virginensis*! It is dwarf, and has tufts of spoon-shaped, viscid leaves, richly bronzed; the short, stout flower-stems are numerous, from 3 inches to 6 inches high, forked, and densely bloomed. They are nearly ruddy, as also are the calices, which

show up the white flowers to advantage. The bright lemon-yellow anthers are also a distinct feature. Herbaceous *Pæonies* had their early growths split by the intense frosts of March, and I much fear their bloom will be unsatisfactory in consequence. The Tree kinds, too, were killed back to the old wood, and though the then dormant buds are now pushing well, flowers will be scarce. *Pulmonaria dahurica* is a gem; its pretty deep blue, clove-shaped flowers are simply exquisite, and the straggling habit of the stems seems to add to its winsome beauty. *Saxifraga Vandellii*, a rare bloomer with me, has flowered this spring in a pot. The flowers are in the way of those of *S. Rocheliana*, pure white, but much larger and almost an inch across when well expanded. It is one of the most stubborn growers I know. The leafy stems resemble those of some Club Moss, being furnished with the old leaves of years back, and only showing rosetted tufts in the green state at the points. J. WOOD.

Kirkstall, Yorks.

GOLD-LACED POLYANTHUSES.

IN Mr. R. Dean's kindly notice of my new seedling *Polyanthuses* (p. 425) he omits to mention the red ground which was shown in London under the name of *Red Exile*, and which was passed over by the judges under what was, I believe, a misapprehension. Its name was unfortunately chosen, as it at once challenged comparison with *Exile*, and Mr. Ben Simonite fetched a plant of that grand dark ground *Polyanthus* from the prize stands and placed them side by side before the judges. It was pointed out by Mr. Simonite that the young flowers of *Exile* came red and exactly resembled in colour my new seedling, and he argued that one was merely a sport from the other without sufficient difference; and so it was passed over. If my red seedling is thus worthy to stand before such competent judges and hold its own against *Crownshaw's Exile*, it is indeed a grand sort, and I am abundantly satisfied. However, to prove its mettle, we exhibited it at Manchester the week following without the name which had proved so fatal to the plant in London—simply as a seedling, and it won both in the threes and in the singles. Thus, then, it has doubly won its spurs, although nameless; and as Lord Derby is one of the subscribers to our northern section, I have taken the liberty of calling it by his name. Red ground *Polyanthuses* are mostly delicate, and especially those sorts which are descended from Sir Sidney Smith through *Lancer*, from which pedigree I think Mr. Barlow's beautiful *Sunrise* originates. If we can get a sturdier habit into red ground *Polyanthuses* it will be a step in advance, and with this object we have used *Exile* and *George IV.* with *Lancer* successfully.

It will have been noticed by florists that *Maund's Beauty of England* has frequently been in the winning lists this season. Mr. Simonite challenged the name of this plant in London, declaring it not to be the true *Beauty of England*, as he well remembered it. What, then, can it be if it thus wins whenever it is properly shown in perfect condition? There is no brighter *Polyanthus* grown; and as my plants were Tom Mellor's, they came from the collection of one of our best florists, who knew as much of *Polyanthuses* as any man. A very old florist was here yesterday, whose father and grandfather before him had grown *Auriculas*. On seeing our *Polyanthus* frame he at once singled out *Beauty of England* as being the true *Pearson's Alexander*, and I believe it will prove to be this, if it is not the *Beauty of England*, as the same remark has frequently been made at our flower shows. Perhaps Mr. Simonite will give you his views on this matter.

With reference to Mr. Dean's remarks about excessive losses in named *Polyanthuses*, I consider the cause is twofold. In the first place the plants suffer from over-division, and in the next from being grown in pots. The *Auricula*, which is naturally a rock plant, and which likes a dry soil, is easily managed in pots. But the *Polyanthus*, which is naturally a moisture-loving plant requiring a meadow-like treatment, can never be

successfully managed by continuous pot culture, and it is from this persistence in pot growth that it becomes weakly and falls a prey to red spider in summer and to damping off in winter.

Tom Mellor always grew his show Polyanthes planted out in sod frames, only using the glass coverings during excessive rains and during winter. In this way his plants were kept cool in the hot summer weather, and they grew amazingly strong and healthy. When show time approached the best plants were carefully selected and prepared for showing, and they suffered little if lifted from the frames and potted a day or two before the show. We have followed the same system here lately with marked success, and shall continue it in future. WM. BROCKBANK.

Brockhurst, Didsbury.

GARDEN POPPIES.

THE note of Mr. Knox (p. 425) contains a statement which obliges me to answer it, and therefore, though I have no special knowledge of the subject, I have put together a few remarks for the benefit of any of your readers who may wish to know the best varieties to cultivate. At the same time I shall take it as a favour if experienced gardeners will freely criticise and correct my statements. Poppies were amongst the earliest of garden flowers. The historian Livy informs us that they were the tallest and most conspicuous plants in the palace garden of Tarquinius Superbus at Rome, 2400 years ago. These were probably the Oriental Poppy, of which my recollection extends over upwards of forty years. When first I began gardening I knew two tall perennial red Poppies, then distinguished as *P. orientale* and *P. bracteatum*. The former was the more common in old gardens. It is about 3½ feet high, with large loose orange-red flowers, not opening quite upright, the bud when young being inverted, as in the common field Poppy. *P. bracteatum* is of a stiffer and bolder growth, often a foot taller, the colour rich dark scarlet, the flower larger and opening more evenly, the bud being quite upright from its birth. On the stalk and just beneath the flower are several large bracts. I first raised this plant about thirty-five years ago from seed purchased of Messrs. Carter, and have grown it ever since. Some of the plants were, when I left Eton five years ago, in the same spot in which they were originally planted. They transplant and divide badly, but ripen seed in abundance, being easily raised from seed, and flowering when two years old. Their habit is to rest all the summer and grow all the winter and spring, the leaves dying down in June and reappearing in November. Those to whom I gave seed generally threw the seedlings away on the first disappearance of the leaves, thinking they were dead. These two species are still common in gardens, but are partly superseded by garden varieties or hybrids of them. These are sold by nurserymen under various fanciful and unauthorised names, as *maximum*, *involutum*, *superbum*, *bracteatum*, *speciosum*, *grandiflorum* and so on, but some of the varieties are very good, and certainly improvements on the species. I was especially struck with several which I saw in May last year in the nurseries of Messrs. Smith, of Worcester, who have a fine collection of them raised by themselves. I must next speak about yellow Poppies, that I may disclaim any knowledge of a yellow *Papaver umbrosum*, a plant of which I will say more presently. First there is *Meconopsis*, which is Greek for having the look of a Poppy. The Welsh Poppy, *M. cambrica*, is common in the crevices of the steep dripping precipices on the higher Carnarvonshire mountains, and is a plant I found when I came to Edge fifteen years ago established as a weed in every waste corner of the garden. It is still a most persistent weed, but pretty, and easily kept down. It is a true perennial. Another yellow Poppy-like plant is *M. nepalensis*, easily raised from seed if it can once be got above ground, and uninjured by any amount of cold, but objecting to dry soils and drought. Its life is of uncertain duration, but it generally dies after flowering. Then there is *Cathcartia villosa*, in habit and appearance half-

way between the last two, a fast increasing perennial, easily divided, but not easy to raise from seed—a plant of no special merit.

The seaside yellow Horn Poppy (*Glaucium luteum*) is well known to all. It is worth cultivating for its peculiar foliage, which it retains all the year, and seems in a garden to forget its maritime habits, and to make itself happy in any soil or situation. It is not annual or biennial, as books on botany generally tell us, but a true perennial. Two more Poppies, *Papaver alpinum* and *P. nudicaule*, complete the list of yellows of which I intend to speak. They are neat and elegant garden plants either for a rockery or a dry sunny border. In their normal and typical state with yellow flowers they are pretty, but difficult to distinguish, and are made more so by the readiness with which they vary their colour and form in cultivation, probably forming hybrids. The best varieties are the white and the bright orange. None of the colours can be depended upon to come true from seed, but they may be stored on any spare bit of sunny ground and transplanted even when in flower. They flower late the first year from seed, and live two or three years. I have tried several other perennial Poppies, but those I have mentioned are the best. For annual Poppies my soil is too cold and damp. In the sunny south some of the garden varieties of the common field Poppy (*Papaver Rhæas*) are pretty enough if well grown; but I never could admire any form of the Opium Poppy (*P. somniferum*) sold as Carnation or Peony Poppy; there is such an untidy look about them, and the seed heads are so ugly.

But I must keep room to speak of *P. umbrosum*, the only Poppy which I make a speciality of in my garden. I hardly think I could have spoken to Mr. Knox of this as yellow, and should have been as much surprised to hear that I had spoken of Buttercups as blue. It is a plant to which justice can hardly be done by growing it as an annual, though its natural duration of life is less than a year. It is a native of the Caucasus, and was introduced by Mr. W. Thompson, of Ipswich, about four years ago. The seed of the year should be sown early in August, and care should be taken to prick out the plants in moist soil, and to keep them growing, and to give them plenty of room, for if they attempt to throw up a flower-stalk before winter they may as well be pulled up and thrown away. They should be planted in their flowering places early in November, and will grow all the winter except during hard frost. Every plant should have a clear space to itself, measured by a radius of 18 inches from its centre. By the beginning of May, if well treated, the tuft of root-leaves will be 2 feet across, and the flowering stems showing, and they will be full of flower from the middle of May to the end of June.

In my soil plenty of self-sown seedlings come up where the plants have been, and these make the best specimens, whether transplanted or left. They appear in August. Sowings, especially in spring, are apt to miss. In the first place, Poppy seed keeps badly. In the second place, slugs and other garden vermin seem to have a vicious taste for opium, and clear off the minute seedlings before they have been seen. How certain individual plants escape in the open border where slugs abound is a problem which often puzzles me. If gardeners who have tried *P. ambrosum* only as an annual will grow it as I have described, I think they will never regret their change of method.

Edge Hall, Malpas.

C. WOLLEY DOD.

Anemone coronaria Empress.—It is stated in THE GARDEN (p. 398) that we cannot grow such Anemones as those lately shown at South Kensington from Cannes, but their sizes are not given. I can hardly think that they were larger than the saucer-like blooms of the Empress strain which I have at present in my garden. They are of all colours—crimson, white, blue, and variegated, and many of them measure 4½ inches across. They are, however, not so bright in colour as some seedlings of my own, but the latter are not so large.—W. J. N., *Clonmel*.

SELF-COLOURED DAFFODILS.

ALLOW me a few final words upon the question of self-coloured Daffodils. When in London last week I asked Mr. Barr if the Tenby Daffodil I sent for his inspection, at the same time as that sent to Mr. Burbidge, was a self, and he admitted he considered it as such, although he thought it a faded bloom. I explained that it was cut freshly the evening before and he was satisfied. Mr. Douglas, than whom there is no better authority as a floral judge, was at Brockhurst last week, and I showed him flowers of two varieties which he said were undoubtedly true selfs, and that I might tell anybody that this was his deliberate opinion; and lastly, that renowned florist, the Rev. C. Wolley Dod, wrote me two days ago as follows: "As for self Daffodils, if I were umpire I think you would have won the kettle either with Tenby or *maximum*. Spurious, though it comes out perfectly self, does not retain its selfness to the last, but I think *maximum* is the most self." Our Daffodil campaign has been an interesting one this season, and we may consider the question of self Daffodils quite settled by the discussion. I think most florists consider that if a stakeholder had had the custody of Mr. Burbidge's kettle it would have now figured in my museum. WM. BROCKBANK.

Brockhurst, Didsbury.

PANSIES IN POTS AND PLANTED OUT.

EXIT Auricula, enter Pansy, and this without any disparagement to the Auricula. Not that Auriculas are quite out of bloom, for some of the later flowering varieties are at their best, and lovely they are, but their floral beauty will soon be gone to appear no more until next spring. The Pansy, in pots under cover and in the open air, is just getting into a state of lovely floral development. As I want them to succeed the Auricula in my north house, they are only just now being put into their flowering pots. It is late for this operation in a general way, but when space is limited one must wait until opportunities offer themselves and they can be utilised. I have about thirty plants in 3-inch pots which I am shifting into 5-inch ones. They are grandly rooted, and they show this by their vigorous growth and the freedom with which they are throwing up young growths from about the base of the main stem, and they are yielding me fine blossoms—yellow grounds, white grounds, selfs of various colours, and fancies. As soon as the plants are shifted the flowers will be kept picked off until the plants are established, and then they will be allowed to bloom freely. The plants came to me in the first instance by post, and as soon as received they were potted into small pots, using a compost made up of leaf-mould, well decomposed manure, yellow loam, and sand. This made a nice, light, rich compost, and the roots soon began to work in it. I am now shifting (as before stated) into the large pots, and am using the same compost. As soon as repotted the plants will go into the north house, where there is ample shade, and here they will bloom with Mimuli, tuberous-rooted Begonias, a select collection of Fuchsias, zonal Pelargoniums, &c. It may be said that these Pansies will not flower until the middle of June, when the sun is hot and the atmosphere dry, and that such conditions are unfavourable to the perfect development of the flowers. There is some truth in this. It is a fact that the most perfectly developed and marked flowers are those which can be had in April and May, but with care in cultivation, with attention to cleanliness, by giving the plants the benefit of cool shade, and stimulating them with a little liquid manure administered at intervals, wonderfully fine flowers can be had at midsummer. On

PLANTS IN THE OPEN AIR in summer without shading the flowers will be imperfectly marked. It is always so at that season of the year unless the summer is continuously wet, and then good blooms can be had. It is in spring and autumn that we get the finest blooms in the open air. In the case of beds in the open ground, they need to be well cared for just now. Finding that the blasting,

icy winds of March had destroyed some of my plants, I recently lifted and replanted the whole of them. The wet winter and the absence of the disintegrating influences of frost had operated to cause the soil, naturally heavy, to run together and become hard and unworkable. This was remedied by digging the beds over two or three times, breaking the lumps in doing so, and working in a good dressing of road grit, soil from the potting bench and Cocoa-fibre refuse mixed together. The plants, assisted by the recent rains, are working into it nicely, and they are growing and blooming freely. This is as it should be. The next thing to do is to keep the surface soil stirred, so that it does not bake, and adding some top-dressing at times, watering freely during dry weather, but taking care when doing so to give a thorough soaking, so that the roots may be well moistened. There is nothing like top-dressing for Pansy beds. During summer free-growing plants send up young growths from the roots, and it is of great advantage to provide a rich light surface dressing so that they can have something to root into. If this be not provided the plants will dwindle away and die. There is this further advantage in encouraging these young growths, that it supplies a number of young plants when the stock plants are divided at the end of the summer. And now the question arises, what

VARIETIES OF PANSIES out of the many to be found in catalogues are best worthy of cultivation. The following from Messrs. R. B. Laird & Son's (of Edinburgh) collection will be found to comprise varieties of the highest quality. Selves: yellow—George Murray, pure yellow, very fine; Zama, yellow, of fine form, and very smooth; George Rudd, deep golden yellow, very fine; white—Mrs. Dobbie, white, with dense blotch, smooth and fine; Mrs. Goodall, pure white, very fine; and Peerless, creamy white, large and fine; blue—L. T. Fleming, bluish black, large and fine; Sunny Park Rival, dark blue, very fine; and W. J. Rawlings, azure blue, extra fine; purple and black—A. Fox, very dark glossy purple, smooth, and extra fine; Beacon, dark maroon, extra fine; Captain Elder, light purple, extra fine; David Malcolm, really black, very striking; George Keith, dark, exquisite form and texture; and Rev. D. Taylor, dark purple-maroon, extra fine. Yellow grounds: Lianet, deep golden yellow, belted with bronzy crimson, extra fine; Lizzie, lemon-yellow, light bronze, purple belting, very good; Alexander Whammond, rich yellow, bronzy purple belting; Captain Cowan, deep golden yellow, belted with bronzy purple, very fine; Ebor, deep golden yellow, belted with dark bronze, a fine show flower; Ita Murray, yellow and deep bronze, very broad belting; Master Ord, yellow, dark bronzed belting, fine and striking; Mrs. Russell, light yellow, belted with bronzy purple, extra fine; Perfection, golden yellow, belted with dark purple, one of the finest Pansies ever offered; Pilrig King, rich golden ground, dark margin, very fine; and The Favourite, yellow, with a narrow purple belting, extra fine. White grounds: Alice Downie, light cream, belted with purple; Duchess, pure white, belted with dark purple; Ladyburn Rival, white, broad purple belting; Miss Bessy McAslan, white, light purple belting, a very fine show flower; Miss Fergie, pure white, belted with deep rosy purple, fine form and very smooth; Miss Jessie Foote, pure white, belted with light purple, fine blotch; Mrs. R. B. Matthews, large flower of exquisite form, pure ground and deep glossy purple belting; Princess of Wales, pure white, belted with rich maroon, extra fine; Sunnypark Beauty, white, with light purple margin; and Undine, white, with a very light purple belting, extra fine form.

THE FANCY VARIETIES I will leave for a succeeding paper. In concluding, I can but express my regret that the south of England generally is so unfavourable to the well-being of the Pansy in the open air during summer. It is too hot and dry, the plants get affected by thrips during a period of drought, and they suffer heavily from mildew from the same cause. Those who grow them do so under difficulty, but they were difficulties our

forfathers overcame to a great extent, and why should not we? Perhaps there is a tendency in the present day to give up the cultivation of flowers that require more than ordinary care to bring them to perfection. But there is something glorious in triumphing, and the true love for flowers is in the heart of that man who is determined to develop the best of any particular subject in spite of obstacles that may lie across his path. R. DEAN.

WATER LILIES.

MR. KINSMAN, of Warren, has written to me occasionally about Water Lilies and his manner of growing them. A letter I had from him the other day concerning them is so full of interesting information, the result of his experience, that I thought if published it would encourage and guide others in the cultivation of these beautiful flowers.

"I live," says Mr. Kinsman, "upon the bank of a mill-pond, on the Mahoning River. The rear end of my garden slopes down to the river, which sometimes rises more than 3 feet above the usual flow. The main current is on the side opposite to me, and every year deposits a rich bottom mud on my side. I set out all of the hardy Lilies, including the *Nelumbium speciosum*, leaving them to take care of themselves. I find that they are all fond of good rich earth, well mixed with rotted manure. I find my best *Nymphaea tuberosa* at the mouth of a drain from my house and barn. Two years ago the mill-dam making the pond was let down, leaving the ground bare where the Lilies were planted. I set some men in and built up a mud bank enclosing a pond at a bend in the river, next to my garden, 50 feet by 100 feet in extent. This mud bank or wall was raised up so as to make a walk around the pond at all ordinary stages of water. I built fences down to the walk strong enough to protect the pond from any floating ice, and guards at the ends of the fences to prevent intrusions on my garden and grounds, leaving the walk around next the river open. In this pond I put my choicest Lilies, leaving an abundance on the outside for the public to prey upon. I put three pipes into the embankment 15 inches in diameter, to let the water flow in and out with the rise and fall of the river. I have kept the roots of tender sorts in boxes through the winter, set in wash-tubs with a tap at the bottom to once a week draw off the water, then filled up my water tank in which they remain quietly until spring. I then take out the boxes and tubs in time to give them the heat from my hot-beds for a start for summer bloom. I have never arranged for winter bloom, but the blue Egyptian has given me some early winter bloom from the tub.

"Four years ago I procured from Chautauqua Lake a small white lily, more like *Nymphaea odorata* in size and colour more than anything else; also *N. tuberosa*, large, white, from Conneaut Lake, Pa. Of these I put out about a dozen of each kind, setting them as you would set an ordinary root on dry ground. The water was about 2 feet deep in ordinary height. Of my Chautauqua Lily, the pond is white with the blossoms in summer, and it has also spread outside of the pond. I received from Mr. Gray the Boston *N. odorata*, to compare with the Chautauqua form, but I was absent from home last year when they were in bloom, and did not see them." I do not see much said about *N. tuberosa*. It is the most luxuriant Lily I have, and I think more generally admired than any other. It luxuriates anywhere in the country, but is especially copious in the west and south. Its flowers are large, white, and showy, but they lack the delicious fragrance with which *N. odorata* of the Eastern States is so richly gifted; hence the fragrant Lily is the favourite. "*N. odorata delicata* has done well with me. It blossomed the first year I had it, when its flowers were of a pinkish shade, but it lost that in the second year's blooms. I got the Boston red (*N. odorata rosea*) last year, but it has not given me any blossoms yet. *N. alba* (the English waxen Lily) is a very desirable species; it did finely with me last year, and lasted in bloom till the frost came. *N. flava* (the Florida yellow Lily) I have had for two years, but it has

not blossomed. I put it out into the pond with the others, but it has not looked healthy. I have thought it possible that it might require the same culture as the *Sagittarias* (Arrowheads)—between land and water." As the plants advance in age they have a peculiar tendency to elevate their crowns into the water several inches above the soil in stilted-up fashion—different from most Lilies. Should these crowns rise above the water they would not have the protection of earth or water, consequently get sunburnt. This has led me to surmise that it may be a deep-water Lily; but the accounts of its growth in Florida which I have seen are too meagre to guide us in cultivation, therefore I believe that the best thing we can do is to experiment for ourselves. Its behaviour here proves that it will grow, thrive, and blossom in moderately deep water; that it is hardy if its roots are kept beyond the reach of ice; that its open-air blossoms are finer than those which it bears under glass, and that it spreads and multiplies itself exceedingly by means of runners. "*N. coerulea*, or the blue Egyptian Lily, wintered well and came out early, but was in August attacked by aphides and musk-rats. The rats ate the blossoms, so I took it up to finish blooming in the greenhouse. Of *N. devoniensis* I had two small plants, but I did not start them in time; one failed, and the other came out right and bloomed until killed by November frosts.

"I have had *Nelumbium luteum* for three years, but it has not blossomed. I account for this by its being crowded too much, and also by its being grown in too shallow water. Last year it got into deep water and showed more than a hundred sprouts, so that I feel sure of a good bloom from it next year. *N. speciosum* has proved thus far quite hardy with me. I got a root of it in 1881 and planted it in my pond. It did finely, and gave me ten full blossoms the first year. I did not take it up for winter, and last year it came out about the last of July or first of August, and continued in bloom till frost came in November, and spread out, say 30 feet, around the main stalk. It is a very vigorous and rapid grower; last year it pushed its way through the mud embankment and came up outside. I had in the river, before I began to cultivate these Lilies, the old yellow "Spatter Dock" and two or three varieties of Arrowheads. The latter I dug up too abundantly, as now I wish I had more of them."—W. FALCONER, in *Country Gentleman*.

FLORISTS AND THEIR FLOWERS.

No one, I should think, could have seen Mr. Waterer's collection of Primroses at South Kensington without admiring them, but it is to be hoped your correspondent "J. M." is alone in the bellicose feeling which these simple flowers seem to have aroused in him. Cannot he admire garden Primroses without disparaging florist's Auriculas? That the "pip men" at all events have no such feeling was shown by the beautiful collection of Primulas and Primroses from Mr. Llewellyn, Mr. Dean, and Mr. Brockbank. "J. M." may not like the florist's Auriculas, but to speak of the splendid show of April 24 as "the poor little exhibits of the pip men" displays indifference not only to the flower, but to fact. So far from the public not caring for the Auricula of the florist, it is known that there is a yearly increasing number of cultivators who, like myself, have had no opportunity of becoming intimately acquainted with the "points" of the flower, but who have been attracted simply by its beauty as seen at these shows. What "initiation" indeed can there be needed for the appreciation of such flowers, for instance, as Colonel Taylor, or Imperator, or Charles Perry, or Heroine? Nor are the "pip men" or the amateurs alone in their attachment to the Auricula. More than one old nurseryman have I heard express his intention on retiring from active work to settle himself down with a frame of these charming flowers as his pet hobby. A flower that has this great fascination for all classes alike has clearly much more in it than seems dreamt of in the philosophy of "J. M." The florist, be he "pip man" or not, may well

feel more than ordinary devotion to his flowers. He is more often than not a dweller in or near a great town, where he finds his Auriculas, his Carnations and Picotees remain his faithful companions and his friends when nearly every other flower has refused to live with him. "J. M." says that only delicate kinds can be expected to be developed by putting a hardy plant coming from the coldest mountains of Europe in a greenhouse or cold frame. But this is not done so much with the view of shielding it from cold as to protect it from the excessive wet of our autumns and springs, which not only spoils the blooms, but constantly rots the plant. Plants put out of doors under the superior climatic conditions that may be had in the country may thrive in spite of all the rain that falls, but near town it is certainly otherwise. For my own part, I have lost so many plants of alpine Auriculas, Carnations, and Picotees, and other subjects planted out during winter and spring, that I look upon the cold frame as the sheet anchor of town gardeners.

M. R.

NOTES AND READINGS.

PLANT NOMENCLATURE.—Nobody, we presume, contends for the use of English names, except for garden flowers. To extend them further or much beyond typical varieties would lead to confusion. In orderly and intelligible arrangement the botanist has the best of it, but popular English names would greatly help to familiarise lovers of flowers with garden plants. Latin names are not, as a rule, applicable or acceptable to such people who yet feel the want of a nomenclature every day in their intercourse with one another. Classes and orders, or even species and varieties, they have not the time nor the will to concern themselves about; nor do they need. All they require to know is the name of the flowers in their borders which are familiar enough to them by sight, but totally unknown to them in a botanical catalogue; hence many amusing blunders are the result, ladies and gentlemen buying and receiving in presents plants, on the strength of a name and a recommendation, of which they may have thousands in their own garden. Popular names that become permanent are usually given on the spur of the moment.

*

THE LABOURS OF THE FLORIST.—Mr. H. Bedwell, writing to the *Field*, desires to know what the florist has not done in producing marked and distinct features of difference in shade or colour in the Auricula, to which the editor replies that there are five varieties of colour. Most opportunely that king of Auricula growers, Mr. Ben Simonite, in a letter to a provincial newspaper last week, throws some light on the labours of the florist resulting in this achievement. "It has been the work of hundreds of years to bring it to its present high state of perfection," he writes. It would appear, therefore, that the progress of the florist has been as slow as his expectations have been high and his patience remarkable. According to the same competent authority, there has been a sad falling off of enthusiasm among cultivators. "Early in the present century the Auricula was a favourite everywhere, and exhibitions were held in all the principal towns in England." Mr. Simonite enumerates the necessities of Auricula culture. How to grow plants in the rockery or on the border we are not told, but the Auricula fancier must possess himself of glass frames, mats, loam, leaf soil, manure, sand, and pots; and he must drain carefully, pot carefully, air carefully, protect carefully, and smoke the plants carefully. The following compost, recommended by a once famous florist, is not considered needful nowadays: "One-half cow manure, one-sixth sound Heath, one-eighth rotten leaves, one-half coarse sand, one twenty-fourth soft decayed Willow wood, one twenty-fourth peat or moor Heath, and one twenty-fourth burnt ashes of vegetables; besides the above are recommended bullock's blood, goose manure, night soil, and sugar baker's scum in equal parts as a top dressing in the spring." The contents of the witches'

cauldron were poor compared to this, but Maddock, its author, who lived about the end of the third or beginning of the present century of the Auricula Improvement Association, could be no fool, and no doubt he recommended the twenty-fourth part of Willow wood and baker's scum, &c., for good and specific reasons. Seriously, I do not despise the labours of the Auricula man, and if he "wad only tak a thocht and mind" and give us plants for the garden instead of consumptive varieties to be from the beginning to the end of their lives in the nursery, he would be forgiven all his foibles. It is not the aid of glass and coddling that has enabled him to effect the changes he has effected in the Auricula's shape and colour.

*

MR. WRIGHT, in a contemporary, says, speaking of Belgian and English leaf-soil, that leaves for leaf-mould should never be heated. This, he says, is Mr. Barron's advice, and is borne out by recent observations of his own regarding Belgian Camellias and Azaleas, the luxuriant growth of which is attributed to the nature of the leaf soil they are potted in. "Persons who endeavour to imitate the compost in which the plants arrive" find that the plants "no longer flourish as they did before, however carefully they may be tended in other respects," the writer states. Is this so, may we ask? Our experience is that very few imitate the Belgian compost, not finding it needful, and it will be admitted, we think, that if we do not propagate Azaleas as extensively as the Belgians do, we at all events grow as good, if not better, specimens. Belgian Azaleas of the trade stamp are good, because, as English growers say, the Belgians make their culture a speciality, and now grow the plants, not in pots, but planted out, the imported plants sold in this country seldom being pot-bound. The difference between Belgian leaf-soil and ours, it appears, is that the former is allowed to decay naturally, while we ferment ours, causing the "formation of acids and gases in the absence of oxygen that are inimical to plant growth."

*

FINE VARIETIES OF ORCHIDS.—Abundant importations make it clear that we shall have to modify our ideas concerning the hitherto regarded splendiddissas. gloriosas, and incomparables among certain classes of Orchids. First acquaintance with new and better forms tempted growers to apply high qualifying names that left no room for the extolations of future importations, and the consequence is there is now a dearth of adjectives in the dead languages wherewith to describe the recent contributions in the shape of Cattleyas, Dendrobiums, Vandas, and the like. The cry is still they come, and nearly every batch furnishes the finest forms which improve themselves the stronger their bulbs grow. The white petalled and sepalled Cattleya Mendelli, for example, of the grandiflora type is no longer a stranger to growers—nay, it is even surpassed by others, and the same could be said of C. Mossiae, Vandas, Dendrobiums, Odontoglossums, Cœlogynes, and others. Every season the importations continue to increase in number and quality, and if Orchids increase as slowly as those who profess to know most about them would have us believe, those best localities which every collector professes to seek must soon be robbed of their treasures for some time to come; and from the way the trade and others are running after importations, this state of things seems to be realised—it is whoshall have the last hanl. We shall be having a duty on Orchids before long. There are now two prominent auctioneers in the field, and both appear to have plenty to do.

*

THE BANNER PLANT (Anthurium).—The large-spathed varieties of this plant are highest priced, but those who are wise prefer the smaller flowered, but freer flowering, varieties, these being far prettier, as well as more useful. The varieties vary considerably in colour, some being a vivid scarlet and others crimson of intense shade, but none of the Scherzerianum variety are poor; not so the new Anthurium Andreanum, with its greater glitter, but less artistic shape of flower—sometimes

amounting to deformity. There are also visibly good and bad kinds, some of them being of a not very attractive brick-red hue. At the late Manchester show hardly one perfectly formed flower could be seen.

*

DAFFODILS IN POTS.—Those pots of the Hoop-petticoat Daffodils at several shows lately attracted much attention, a circumstance not to be wondered at. It is a matter of surprise, indeed, that the Daffodils have not long ere this been added to our indoor bulbs. They have frequently been mentioned as suitable for forcing, but they have not hitherto been generally employed for that purpose. They are no novelty in April or May in pots, but we have seen the smaller varieties, including N. Bulbocodium, in flower in February and earlier in a small amateur's vinery years ago, at which season they are a treasure. The slight assistance they need in the way of heat can hardly be called forcing; and yet the Daffodils are but one of the many species of hardy plants that might be used for the winter and early spring decoration of our conservatories and rooms. Mostly all our spring and early summer flowers force freely—Primroses in variety, Arabis, Candytufts, Lithospermums, Wallflowers, Stocks, Iris, Scillas, Forget-me-nots, &c., and afford a rare reserve for those who like to have early flowers at the least cost.

*

AUSTRALIAN APPLES.—We notice that very little is said about the eating qualities of these Apples. Two or three years ago, as was mentioned in these notes, the writer was struck by the extraordinary beauty and perfect appearance of examples of Apples in a well-known fruiterer's window in Manchester about this season of the year, and found on inquiry they were from Australia, but as poorly flavoured as they were good-looking—being, in fact, quite insipid and almost tasteless. The fruiterer shook his head over them.

*

FLORISTS AND THEIR FOIBLES.—The Rev. Mr. Tymons should not complain of criticism, especially in reference to a writer like the one quoted in last notes, who praised a florist's flower because it looked as if it had been coloured by a painter's brush, and lectured the general public for not seeing beauty with his eyes; besides, have not florists in times past insisted that their "rules" and "standards" were perfect and all others wrong? and have they not written, and published, and lectured, and exhibited, and been generally aggressive and dogmatic whenever the merits of their favourites were discussed? Why, too, should they fear criticism? I daresay there are many amiable men amongst them; in fact they are not accused of anything but of narrow and rather contracted views that have hampered their progress from the beginning. We refuse to recognise the Auricula, Tulip, or Pansy "florist" in the Veitchs and Cannells who have given us those popular races of flowers that everybody grows and can appreciate, and Mr. Tymons knows as well as anybody that the "fraternity" have had little or no hand in such work. It was only when the work was taken out of their hands and conducted on broader lines that any great strides in improvement were made. The old florists' "points and properties" were unintelligible to the general observer, as the writer on the subject of "thrum centres" and "florists proper" tells us; whereas the modern florist tries to give us flowers the properties of which appeal to everybody at the first glance, and does not concern himself in the least about foibles.

PEREGRINE.

To protect iron and steel from rust.—Prof. F. Grace Calvert has discovered that the carbonates of potash and soda possess the same property of protecting iron and steel from rust as do these alkalis in a caustic state. If an iron blade is half immersed in a solution of either of the above carbonates, it exerts so protective an action, that that portion of the iron which is exposed to the influence of the damp atmospheric

air does not oxidise, even after a period of two years. Similar results have been obtained with sea water to which have been added the carbonates of potash or soda.

ROSE GARDEN.

ROSE PROSPECTS.

THESE can hardly be said to improve as the season advances. Neither, to be exact, can the season be said to advance, unless it be backwards, for March weather in May has hitherto been the order of the day. With the wind glued in the east or the cold north; showers of rain alternating with hail and snow-storms; the warm sunshine of the day succeeded by sharp stinging frosts at night, the resuscitation of sorely hit and crippled Roses can hardly be expected. Hardly, in fact, have they ventured to put forth a fresh green leaf till it is shrivelled and blasted by the cutting winds or stinging frosts. And this process of growth and arrestment or total destruction of growth is being repeated again and again. All this involves a serious loss of time as well as of vital force, and the danger is daily becoming more imminent that the latter may become exhausted in this zig-zag process of growth and destruction. No doubt a thorough change of the weather might do a good deal to brighten the prospects of rosarians. But of this there seems but little hope. Somehow or other May has mostly of late years proved almost the most ungenial month of the twelve to cultivators. And were it from this 7th day to prove as genial and warm, as could be desired, even such stimulating weather would fail to restore dead Roses to life again, and more and yet more plants are dying daily. It might, however, do very much indeed to strengthen and invigorate weather-beaten and frost-bitten Roses, and these are far more numerous than the absolutely dead. In fact, the majority of Roses are more or less injured, and as the season advances the injury becomes more apparent. Few things are more deceptive than the first attempts to grow of frost-stricken plants. The more deeply they are injured, often the more haste are they in to grow. This seems in accordance with a general law that haste is more frequently allied with weakness than with strength. Be that as it may, hardly had the frosts of March ceased to bind the Roses than they began to grow. But April, though less severe, was hardly more favourable than March. In some respects it was even less so, for in April 6° of frost is more potential to injure Roses than 20° in March. Hence the serious danger and augmented injury arising from frosts in May. It may, in fact, be almost accepted as an axiom that the later the frosts the more injurious. This principle has recently been illustrated with disastrous effects among our Roses. We are now engaged in what we trust may prove

THE LAST PRUNING of our Roses this spring. The majority of the Perpetuals were pruned early in March. The severe frosts pruned them a second time. Towards the end of the month they were looked over again. And now in May the dead and injured portions are being cut out. After all these prunings, mechanical and climatal, it will readily be seen that little flowering wood remains on many of our Roses. Where that little, however, is sound and healthy, there is a sure basis left for the renewal and re-invigoration of the future plants. This season severe cutting back has been rendered compulsory, with what ultimate results remains to be seen. Its immediate effects must of necessity be a later Rose season and fewer flowers than usual.

DWARF ROSES ON THEIR OWN ROOTS have had the best of it this season. These where unprotected and not earthed up may, in general terms, be said to be killed to the ground-line. But an inch or less from this magical dividing line between earth and sky the Rose collar and base of branches are absolutely safe, and from these there are springing forth such strong beginnings of giant-like shoots that promise a speedy rejuvenation of the bushes. Even most of the Teas

seem healthy from an inch to an inch and a half below the ground-line. These are, however, rendered safer by an earthing of 2 inches or 3 inches, or by a mulch of any kind ranging in depth from 2 inches to 6 inches. The only difficulty about mulches consists in knowing when to remove them. This season, for example, those that disearthed or unmulched their Roses in April have probably had their most promising breaks killed back. But in all cases where these base breaks have escaped, they appear among the most cheering prospects to the rosarian on this the first week of May. The next most gratifying prospect is the fresh and healthy state of

TEA ROSES ON WALLS. Where these were protected with Fern fronds or Spruce or Yew boughs, and the protection was kept on sufficiently long, they broke fresh, vigorous, and promising as could be desired. Teas on walls unprotected, including Gloire de Dijon, are terribly punished, nearly all of the first breaks and much of last year's wood being destroyed. As usual when Roses are severely injured by frost, the maggots are early at work among them. When food is scarce, there not only seems to be, but actually are, I believe, more maggots to devour it. Hence the special importance of vigilance and promptitude in their destruction. Aphides will also most probably follow sharp on the heels of recent frosts. There seems an abnormal sweetness in semi-frozen leaves that specially invites, increases the number, and develops the strength of these pests. Finger and thumb, an aphid brush, a dash of Tobacco juice, or a pinch of snuff are the most summary and efficient remedies. Crippled tops also develop root and stem suckers to an abnormal extent. Remove all the former and most of the latter, unless the tops are in such a bad way as to suggest the wisdom of a renewal by a fresh start, in which case one or two of the best placed stem suckers may be left for budding. Where this is done the old top should be bodily removed immediately after blooming or at once should the prospect of bloom not prove promising. Weakly Roses might often be strengthened considerably by the removal of all flower buds so soon as they show. This course obviously involves a great sacrifice of beauty. Still it is far better to lose one crop of bloom than to lose the Rose bush, or merely prolong its life in a state of weakness. Hard pruning and the removal of all flower buds from weakly plants are two of the most powerful recuperative measures at the command of the rosarian, and it is seldom that they have been more needed or would prove more useful than this season. D. T. F.

BRIERS WITH DEAD TOPS.

THE Roses are dead; up with them, root and branch, is too often the impetuous decision of the rosarian, soured with disappointment. Yet a moment's reflection would show that much root force and stem accommodation are lost by the destruction of Briers that may have lost their heads. In many cases nothing is injured but the Rose, which, in most cases, is more tender than the Brier. In many more, however, part of the upper portion of the Brier is also crippled, or has died back, partly probably in sympathy with the dead Rose, or from the biting severity of the frost. But wherever any portion of the stock is left safe and sound, the wisest plan is to cut back to this and await the result. In most cases growth is as sure and satisfactory as possible. One or many strong shoots burst forth from the stem. One, two, or at most three, of these, if placed pretty closely together, should be selected for budding. The best placed, as well as those highest on the stem, should be chosen.

In standards with frozen heads there seems an abnormal tendency to the production of rootsuckers. The sap suddenly arrested in the Rose crowns appears to rebound to the lower extremity of the plant. Not being needed there for any other purpose, it is at once expended in the production of suckers, and these need prompt and immediate suppression to secure strong and early shoots for budding. Occasionally, however, the whole Brier

stem is so withered up or blighted by the frost, that the better way is to cut it off by the ground line, and from thence a root sucker may be led up for future use. These casual suckers will at times be of such giant-like dimensions, that a Brier a yard high and of sufficient thickness for a standard may be thus provided fit for budding on in July or August. By either of these systems vital force is husbanded, and root force turned to the best account in filling up the cruel blanks made by the frost among our Roses. H. H.

TEA ROSE ADAM UNDER GLASS.

THIS is assuredly one of the most delicately beautiful and floriferous of all the Teas. It was raised by Mr. Adam, of Rheims, and sent out in 1838, and has therefore been more or less known to rosarians for 45 years. Singularly enough, however, it was rather less than more known, and in consequence was rechristened President many years after its introduction. As an old cultivator of Adam chiefly under glass, and a grower of President in the open air, I was one of the last of rosarians to admit their identity. Grown under such diverse conditions, the Roses are far more distinct than some others rejoicing in different names. But under identical conditions of soil, site, climate, culture, Adam and President coalesce into one. The final test submitted to me was a mixture of buds and expanded blooms, and inability to distinguish or separate them. Adam varies very much in size grown under different conditions. Some of the catalogues describe it as very large and full. When it reaches a state to warrant this description, this charming Rose is already spoilt. Like Devoniensis and so many other charming Tea Roses, Adam is far away most beautiful in bud. When fully opened it is globular and full. The colour in bud is a deep full rose; as it expands the colour is less deep, with a perceptible shade or touch of salmon. Though not one of the fullest scented Teas, such, for example, as Maréchal Niel or Devoniensis, it is nevertheless sweet, and altogether is an invaluable Rose.

IN THE OPEN AIR the tints are somewhat deeper and the fragrance fuller than under glass. But for bouquet and other purposes the greater delicacy by no means lessens its value. The form is also modified under glass, the buds especially becoming more pointed. The protection of glass also develops to the full the natural and extraordinary floriferousness of this useful Rose. In the truest sense of the word glass alone renders this Rose perpetual. Add sufficient heat to command a temperature of 45° to 50° throughout the season, and few weeks or days need pass without being enriched with the beauty of an Adam Rose or Roses. In an unheated passage we gather four crops a year with a good many straggling blooms between. It is our earliest and latest blooming Rose. Its first harvest of beauty appears in February or March; its last mostly amid the fogs of November. By cutting the flowers pretty closely back when almost half or three-quarters open the habit of perpetual blooming is hastened, strengthened, and more fully developed. No Rose with which I am acquainted, with the single exception of Gloire de Dijon, will

BREAK AND BLOOM so rapidly on the heels of the knife as the Adam Tea. The growth is moderate rather than vigorous, but it is prompt and perpetual, and with anything like careful culture this Rose seldom produces shoots too weakly to bloom. It so happens that our finest plant has a border about 6 inches wide and 18 inches deep to grow in. This is hemmed in on one side by a brick wall, and on the other by a stone path. True, the roots are fed with a good many sewage dressings throughout the season; but even with these the roots must have a straitened, hard time of it. No doubt the Rose would do still better under more favourable root conditions. But as it is, I should not like to give a statement of the number of blooms we cut from it during the season for fear of being accused of exaggeration. Those who have room for but one Rose under glass cannot do

better than choose Adam; while those who have space for several kinds should see that several of them are of this self-same variety. For many years I have found Adam the most useful of all Tea Roses for pot culture, running up rafters, or for the clothing of walls. D. T. FISH.

INDOOR GARDEN.

INTERMEDIATE HOUSE PLANTS.

For the information of "Ixion," who (p. 415) inquires respecting intermediate house plants, I may say that no absolute line separates them from stove plants such as there is in the non-ability of the latter to live and thrive in a greenhouse. In most cases intermediate house plants need more air, a somewhat drier atmosphere than stove plants and less shade, but not all, as there are some that will not do with less shading than the tenderest leaved of the stove occupants—for instance, the *Franciscas*, especially *F. confertiflora*, one of the most beautiful of all flowering plants, and which cannot bear the sun's rays to reach its foliage except in the two last and two first months of the year. As to the temperature that should be maintained in such a house, it will be best as near 50° in the night through the winter, as it can be kept without exceeding that figure, with a rise of 6° or 8° in the daytime. During night in summer it may run as near 60° as may be, but except in the hottest weather it will be better not to exceed this, giving air freely in the daytime when hot, but at the same time not subjecting the plants to direct cold draughts, especially in spring when the sun often raises the temperature when the air is yet very keen. In hot, sunny summer weather the heat will as a matter of course in the middle of the day get as high as in the stove, but the extra air given will cause the atmosphere to have a less exciting influence on the plants. It is this that makes the difference in the ability of some species to flower that under the influence of the more confined heat of the stove keep on growing too rapidly to ever get their wood solidified enough to set bloom. With intermediate plants, as with the occupants of the stove, I have found it best not to keep them so long dormant in winter as is often supposed to be requisite, as where this occurs it follows that it necessarily shortens the season of growth, and with it in a corresponding degree the season of flowering of all that have a continuous habit of blooming, or anything approaching to it. For this reason it is best to raise the temperature 5° or 6° during the day at the beginning of March, increasing it as the sun gets a little more power. Amongst

THE BEST FLOWERING PLANTS for growing in such a house may be included *Bougainvillea glabra*, in pots or planted out, and if the house is a large one, *B. spectabilis*, also planted out, but the latter species must not be pruned in before making its growth like the first named. *Anthurium Scherzerianum* does better in an intermediate heat than in the stove, always keeping the roots in fibrous peat, *Sphagnum*, and crocks, like *Orchids*. *Franciscas* *confertiflora*, *F. Hopeana*, *Gardenia intermedia*, *G. radicans*, and, in a roomy house, *G. Fortunei*, *Gloxinias*, *Griffinia hyacinthina*, *G. blumenavia*, *Imanophyllum*, *Lasiandra macrantha*, *Luculia gratisima*, *Mackaya bella* (one of the best of all flowering plants), *Rogiera gratisima*, *Rondeletia speciosa*, *Stephanotis floribunda* (kept dry at the roots in winter), *Strelitzia reginae*, *Tacsonia Van Volkemi* (climber), *Achimenes*, most of the varieties of *Amaryllis*, most of the *Begonias* (including the tuberous-rooted kinds), *Brunfelsia americana*, *Burchellia capensis*, *Hexacentris mysorensis* (climber; kept dryish in the winter), and *Ardisia crenulata* (both the red and white-berried varieties). The above are some of the most suitable flowering plants. The following

FINE-LEAVED KINDS will do well in an intermediate temperature, viz., *Dracena terminalis* and *D. Cooperi* (kept somewhat dry at the roots in winter), *Cyperus alternifolius*, *C. alternifolius* va-

riegatus, *Panicum variegatum*, *Isolepis gracilis*, *Dionaea muscipula*, almost all the Ferns in general cultivation, with the handsomest Palms of small or medium growth, such as *Chamaedorea graminifolia*, *C. elegantissima*, *C. glaucophylla*, *Areca Baueri*, *A. lutescens*, *Cocos Weddelliana*, *Thrinax elegans*, *Pritchardia pacifica*, *Livistona altissima*, *Geonoma Seemannii*, *G. gracilis*, *Kentia Balmoreana*, and *K. Fosteriana*. Although the last two fine Palms will thrive in a greenhouse, still they have a more refined appearance when grown in a little warmth. In a house kept at this temperature all the best

HARDY SHRUBS used for forcing can be brought into bloom during the winter and spring, such as *Deutzias*, *Prunus*, *Rhododendrons*, *Azalea mollis* and the Ghent varieties, *Laurustinus*, *Hydrangeas*, and *Lilacs*, with *Spiraeas*, *Lily of the Valley*, *Dielytras*, and bulbs of the usual sorts that are forced; for although none of these can be brought into bloom so quickly as where more heat is employed, still they will look better and last longer than when hurried. T. BAINES.

ILL EFFECTS OF PLANTING BULBS LATE.

COMPLAINTS are continually made that imported bulbs of *Lilium auratum* which arrive in England in such quantities seldom survive after flowering, their whole energies being apparently exhausted in the production and subsequent development of their blossoms. Their late arrival in this country has in my opinion a good deal to do with this. Great numbers are disposed of by auction in March and even as late as April, while if they had been potted or planted at the proper season, their roots would have been in active operation by that time. When bulbs are potted late they push flower-spikes and roots simultaneously, but neither attain the vigour exhibited in the case of early potted bulbs; indeed, the roots formed at the base of the stems seem to be the principal feeders. Having a large number of bulbs last season that were potted late, I examined them after flowering and found generally that even when the pot was full of roots they were nearly all stem roots; very few issued from the base of the bulb, while in the case of others which I had grown and flowered for several years the roots from the bulb were stout and vigorous, and when potted directly after flowering were soon actively at work in the new soil.

Another point worthy of note in my case was the readiness with which these late-potted bulbs fell into ill-health. I allude to that burnt-up appearance which they present more particularly in hot, showery weather, during which the leaves at the bottom of the stem first turn yellow and then brown, the affection gradually mounting upward till the buds are attacked and drop off, when the whole plant looks as if it had been scalded. After flowering I found that, though a good spike of flowers had been produced, there were but a few partially decayed scales to mark the site of the bulb, and in every case, even if the bulb was still entire, it was much smaller than when first potted. After throwing away all decaying bulbs, the rest were potted and placed in a cold frame, where they are now pushing up spikes, but in most cases so weakly that but a small percentage of bloom will be produced. However, from past experience I am convinced that when once established they will grow and flower every year without any trouble, provided they are potted as soon as the flowering season is over.

Some years ago I obtained a small collection of the different varieties of *Lilium auratum*, among which several have greatly increased in size, while others are neither larger nor smaller than they were half-a-dozen years ago, though they flower well each season. They are all in pots kept in a cold frame during winter and placed in the greenhouse in summer. If bulbs of this Lily could arrive in England about November, and be then potted or planted out, I think we should hear much less about their mortality than we now do, as they would then be well established before the summer set in. The same remark holds good regarding all kinds of Lilies. If kept dry till February or

March their energies are exhausted; while if placed in soil, several roots will certainly be sacrificed when removed. The common white Lily (*L. candidum*), which of late years has been largely imported early in autumn, commences to grow as soon as received, and therefore should be planted at once, otherwise, like others if removed after growth has been commenced, the bulbs will be sure to suffer.

Although these remarks apply more particularly to Lilies, they might be extended to all bulbs disposed of during the spring months in a dormant state. These we frequently see lying about when their roots should be in active operation. In the majority of cases the embryo flower being in a perfect state within the bulb, the difference the first season is not very great, but flowering seems to completely exhaust the bulb, which either dies outright or dwindles away to such an extent that it is too weak to flower. In forcing such things as Tulips, Hyacinths, &c., if put into heat before they are well rooted the flowers seldom expand properly. In short, the great secret belonging to successful bulb culture is having plenty of healthy roots before the flowering season commences.

II. P.

Culture of perpetual Carnations.—The propagation of perpetual or tree Carnations is an easy matter. Cuttings put in in a hothouse on bottom heat strike rapidly in winter. When rooted and hardened for a short time in a pit or greenhouse they may in April or May be planted out in the open ground. They can also at that time stand a long journey. They must be packed in damp Moss without earth at the roots. They require a very airy situation. When planted out they must, if the sun is hot, be shaded for a few days and kept moist, and when in a growing state they should be watered from time to time with liquid manure. When they have grown about 6 inches high they should be pruned back at least one-half in order to induce the growth of side shoots and flower-buds. To have them in bloom during the following winter until April and May, when all other flowers are scarce, they should be taken up about the middle of September, potted in 6-inch pots, and placed on a slight bottom heat in a pit or stove; they should be kept close for about a week and then given air gradually, i.e., if the temperature is about 40° Fahr., as they do not require much more heat than that. Of course plants destined for this purpose must have, when potted, a good quantity of flower-buds; indeed, some will have, if they have been well treated, as many as from sixty to eighty. When the flower-buds begin to expand the plants can be moved indoors. I have had some in my dining-room more than a month, and they are still in bloom, and much admired. They must be placed as near the light as possible. Plants which do not show a sufficient number of flower-buds the first year should not be lifted from the open ground unless the winter appears to be severe. If that is likely to happen they can be taken up with a ball of earth adhering to the roots and put close together in a pit, uncovered as long as possible, and when frost sets in just protected from it, and that is all, and whenever it is possible air should be given. These plants will produce flower-buds, and may be potted in March or April. If potted and put in a stove before they have a sufficient number of flower-buds they grow straggling, lose their leaves, and bloom badly. The largest and best cultivator of perpetual Carnations is Lant. Carle, Monplaisir, Lyons. He makes their culture a speciality, and since he succeeded M. Alégaire he has raised many good sorts. Many have failed in the culture of these Carnations; I hope, therefore, that these instructions may be productive of good results.—JEAN SISLEY, Monplaisir, Lyons.

The variegated *Negundo* forced looks well against the dark glossy green foliage of the *Camellia* and similar plants as a background. For forcing all that is necessary is to pot it early in autumn and plunge it out of doors in some sheltered spot till it is taken into the forcing house just after Christmas. This *Negundo* is generally

grown in the shape of standards, but for many purposes dwarf bushes are quite as good. Small plants of it are readily obtained by budding it on the green-leaved form, but of course they take some time afterwards to grow into plants large enough for forcing. As stocks for budding seedlings are preferred, and the operation should be performed in the same way and about the same time as in the case of Roses. The bark of the stock must be fresh and green, so that it will separate readily and heal quickly. In selecting the buds, do not take any in which the leaf immediately adjoining is nearly white, as the probability will be that in the leaves of the embryo bud the same pale hue will preponderate to such an extent that it will not have sufficient vigour to grow; choose rather buds near where there is a fair proportion of each colour in the leaf.—ALPHA.

GARDEN FLORA.

PLATE CCCLXXXVIII.

DOUBLE AND SINGLE BOUVARDIAS.*

WITHIN the last few years the popularity of the different kinds of Bouvardia has greatly increased; here and there at one time a solitary plant of this genus might have been met with, but now it is no uncommon occurrence to find a house devoted entirely to Bouvardias, and that, too, in private establishments, while some of the large trade growers produce them in enormous quantities, not only for decorative purposes in pots, but also for supplying flowers in a cut state. The latter possess a wide range of colour, and some of them are deliciously scented. They are produced freely on the small lateral shoots, especially after the removal of the terminal cluster, and last, but not least, the plants flower throughout the winter, although by judicious treatment they may be had at almost any season of the year. Bouvardias are natives of Mexico, whence a few species have been introduced at different times, but the sorts now generally grown have originated either in England or in the United States of America, from which have been obtained both of the double varieties represented in the annexed illustration. There are no very striking points of difference between the species except in the colour of their flowers and in the leaves being glabrous or pilose; they are all branching, free-flowering shrubs, and bear tubular flowers produced in terminal clusters.

The principal species are :—

B. TRIPHYLLA.—An old inhabitant of our gardens, and one still grown, but to a limited extent. Its leaves are arranged in a trifoliate manner around the stem, and are more or less hairy. The flowers are small, but borne in moderate-sized clusters, and bright vermilion in hue, a colour quite equalled, if not surpassed, by the next—

B. LEIANTHA.—This greatly resembles the preceding, but is more bushy in habit; the leaves are less hairy, and it is altogether a better grower.

B. HUMBOLDTI and *jasminoides* are two large white-flowered, sweet-scented kinds belonging to the glabrous-leaved section. The first is much surpassed by its variety—*corymbiflora*.

B. FLAVA.—This differs in no way from the ordinary type, except in the colour of the flowers, which are deep yellow, and though borne in rather small clusters, are so distinct that it is surprising it is not oftener seen than it is.

B. ROEZLI.—This is in some respects the most distinct of the whole, especially as regards its root

growth; it forms a large underground root-stock or tuber; the leaves, too, are of a firmer texture than those of any of the others. The flowers are borne in flattened corymbs, but in colour they vary somewhat from deep pink to carmine, and at times have a violet shade. Among the different hybrids or sports great variety exists, and from amongst them I would select the following as the best of the several sections that have come under my observation.

BRIGHT COLOURED KINDS.—*Hogarth*.—Individual flowers rather small, but brilliant; habit good, and one of the most vigorous in constitution. *Elegans*.—The flowers of this are larger than those of the preceding, which in general characters it greatly resembles. *Unique*.—Deep violet-carmine; the outside of the tube pure white; unlike any other variety; said to be a seedling from *B. Roezli*, but without the tuberous-like roots which that kind possesses. *Dazzler*.—Undoubtedly a very fine kind and one not yet known to the extent which its merits deserve, but from the quantities of it in the hands of some of the leading growers it will soon become more common. It is of good habit, very floriferous, the clusters of flowers being large, and in colour deep carmine-rose. It was raised by Mr. Balchin, Hassocks Gate, Brighton, and certificated at South Kensington.

WHITE FLOWERS.—*Humboldtii corymbiflora* differs from the type in the size of its clusters of flowers, which measure over 2 inches long. This kind is brought into Covent Garden Market in great quantities during winter both in the form of plants and in that of cut flowers, the latter being great favourites with bouquetists, and from their size frequently used singly. The club-shaped buds are also striking, and, moreover, the flowers are sweet scented. *B. jasminoides longipetala* is distinguished from the species by the greater length of its petals, but both are alike first class kinds. The leaves of these white-flowered varieties are dark green and glabrous, but in the following they are hairy; the flowers are smaller, nearly scentless, and borne in more compact clusters. They comprise *Bridal Wreath*, *Vreelandi*, and *Davidsoni*, the last specially interesting, as being the variety from which the double-flowered *Alfred Neuner* was obtained. The different

SHADES OF PINK are represented by *Queen of Roses*, *Maiden's Blush*, and *Rosea oculata*, a remarkably floriferous kind; indeed it will frequently continue to flower till quite exhausted. It is of a deep flesh colour with a darker eye. The latest addition to this class is *Priory Beauty*, sent out by Messrs. Veitch last year, and likely when better known to become one of the most popular of the pale tinted flowered sorts. It is of free, yet compact growth, an abundant bloomer, and both the individual flowers and clusters are large compared with those of many others. Colour a soft pink.

THE PALE SULPHUR coloured *flavescens* stands out distinct from all the others; it is said to be a hybrid between the deeper tinted *flava* and one of the white varieties, and the colour would certainly suggest such an origin.

DOUBLE-FLOWED VARIETIES are at present confined to the two here figured. Apart from the consideration as to whether a single or a double flower is the more beautiful, the doubles certainly have one great point in their favour, and that is the blossoms remain longer in perfection than those of single kinds, and where employed in ar-

rangements of cut flowers they do not drop as the single sorts are somewhat liable to do. The double white (*Alfred Neuner*, the uppermost flower on the plate) was sent out by Messrs. Nanz & Neuner, of Louisville, Kentucky, in the spring of 1881, and was first shown in flower in this country at a meeting of the Royal Horticultural Society held at South Kensington in the following summer, and since then it has steadily advanced in popular favour. Concerning the propagation of this variety a good deal has been written, it being contended by some that only cuttings made of the leading shoots retained their double-flowered character, and that the small side branches if struck reverted to the single form. My experience, however, is that there is no hard and fast rule to be laid down in this respect; as it originated from a sport, its character is not thoroughly fixed, and therefore cuttings will occasionally bear single flowers, let them be taken from whatever part of the plant one likes, although the stronger shoots are less liable to become single than the weak ones. Plants propagated from root cuttings I find to be very untrustworthy in this respect, but in cuttings of young shoots taken from healthy plants cases of reversion are so few in number as to be of little moment. In the winter of 1881, having a large number of this *Bouvardia* in flower, I selected two or three, the blossoms of which were more or less tinged with pink and propagated from them, the result being that they maintained that character, but in depth of hue they were before long surpassed by another importation from the States. *B. President Garfield* is, strictly speaking, a pink counterpart of *A. Neuner*, and one liable to sport at times, as among those I have flowered some are of a much brighter hue than others. Both these *Bouvardias* are undoubtedly destined to become very popular.

PROPAGATION.—*Bouvardias* are all readily propagated by means of cuttings if skillfully chosen. The most satisfactory way to set about the work is as follows: After flowering keep them somewhat dryer than before; then early in February place them in a gentle heat where they can be occasionally syringed, and where a moist growing atmosphere can be maintained. The result of this will be that young shoots will be produced from all parts of the plant, and if these are taken off as soon as large enough and while they are still succulent, they will root as easily as *Verbena* cuttings. Care must, however, be taken during the operation that they do not flag to any great extent, to prevent which a propagating case must be used to keep them close till rooted. As a rule, if they have a thorough watering when first put in, and if the case is moist, they will require but little more until they have struck root. It is, necessary, however, to guard against too much moisture, otherwise they may damp off. Root cuttings are not much employed. In order to strike them all that is necessary is to cut the stouter roots into pieces about an inch long, and insert them perpendicularly in pots or pans of sandy soil, keeping them close till young shoots are produced from the top portion of the roots after the manner of seedlings. In cutting up the roots, lay the upper parts all in one direction; otherwise if the pieces become mixed, it is nearly impossible to distinguish the upper from the lower portions, and in that case the chances are that some will be put in in a reverse position. The roots should be inserted deeply enough to be just covered with soil.

* Drawn from plants in Mr. Turner's nursery, Slough, in February last.

DOUBLE FLOWERED RHODODENDRON
EFFLUENT GIFFELL. BY ALFRED NEUNER.

CULTURE.—Where cut flowers alone are required a common and successful mode of culture is to plant out in a prepared bed of soil either in a low house or frame, which can be heated at pleasure. In this way Bouvardias grow more quickly than in pots and yield a proportionately large amount of bloom. Young plants to be grown thus are potted off as soon as struck, given one shift, and then planted out. The soil should be moderately light—say one-third leaf mould to two-thirds of loam, or one-half of each according to the consistency of the loam. After this is done maintain a close growing atmosphere until they have started away freely, and when in full growth they will be benefited by a little manure water. They should be gradually hardened, so that by the middle of summer the lights may be removed altogether, and only put on in case of heavy and long continued rains. Thus by the end of August they will have well ripened their wood, and will be ready under an increased temperature to burst into bloom, when if kept at from 55° to 65° during winter they will maintain a continual supply of cut flowers. The planting-out system is also followed by many for the production of bushy plants, to be potted up in autumn in the same way in which Solanums, Chrysanthemums, and similar subjects are done. For this purpose they should be planted out about the beginning of June, and though they will grow in the open in summer without any protection, yet it is desirable to have them in a frame, as in that case the lights can be put over them when required. The middle of September is a good time in which to lift and pot them, operations which should be done carefully. When potted they must be kept close and warm for a few days till they recover from the check received; after that all that is necessary is to keep up a temperature of from 55° to 65°, or even a few degrees higher, in order to maintain a supply of flower throughout the winter. The method followed by growers for Covent Garden Market, and certainly the most satisfactory for the production of small plants, is to confine them always to pots, treating them much in the same way as regards potting, stopping, &c., as Fuchsias, except as respects the increased heat during autumn and winter.

SUMMER FLOWERING.—There is no difficulty in obtaining a supply of Bouvardia flowers throughout the summer months if the plants have not been allowed to exhaust themselves previously. My attention was first directed to this by a number of the scarlet Hogarth that did not flower much in the winter, but on being planted in the open ground when the season was sufficiently advanced produced a great quantity of blossoms throughout the summer months, when, though flowers are plentiful, such chaste subjects are always valuable. The white Humboldt corymbiflora also flowers well in this way; and last spring, having some small plants of Alfred Neuner, I potted them on, and placed them in an intermediate house, with the result that they grew away freely, and by June were in full flower. It will thus be seen that the Bouvardia readily adapts itself to the different circumstances under which it may be placed.

H. P.

Fireballs.—To make these take two parts small anthracite coal, one part clay, one part sand or chalk; thoroughly mix these together with sufficient water to make the mixture of the consistency of mortar; then make it into balls and stack them in a dry place. The fire should first be fairly started and the balls placed on the top. They will yield a strong and lasting heat.—W. C. T.

SEASONABLE WORK.

FLOWER GARDEN.

EUONYMUSES.—The variegated Japanese varieties of Euonymus are among the best of the many introductions of late years that can be effectively used for flower garden purposes, not their least recommendation being that they are all but quite hardy. The two recent severe winters somewhat injured plants of them in this district, but none were killed outright, and after such a trial it may safely be inferred that they will withstand our ordinary winters. The small-leaved kind, *radicans variegatus*, is, in habit of growth, half bushy and half climbing, and can, therefore, either be used as a covering for low walls and trellises, or with a little attention to trimming be grown as a hedge. As a permanent edging plant to large beds cut and trimmed, as is usual with Box edgings, few plants are more suitable. The varieties *aureus marginatus* and *argenteus marginatus* are stronger growers, and have large and richly variegated foliage; the growth of both kinds is somewhat loose or straggling, a defect that is easily remedied by occasionally pinching out the points of the longest or unevenly developed shoots. Plants grown in bush or standard form make excellent and permanent centres for beds of high-coloured Pelargoniums or dark-foliaged plants, and for intermixing with bright green foliaged plants in the outer lines of shrubberies they are invaluable. They strike best from cuttings made of the well-ripened wood of the current year's growth; hence autumn is the time to propagate them. Light sandy loam or peat, the cuttings well firmed in it, and the pots plunged in ashes in a cold pit protected from frost, are all that is needed to ensure a successful strike.

BEDDING OUT.—With the exception of the most tender, such as Coleus and Alternantheras, all other kinds of summer bedding plants may now be planted, and in arranging them the less elaborate the designs and the quieter the colouring the greater and more lasting will be the enjoyment of the garden. Another thing to avoid in the arrangements is excessive formality or flatness; this is easily prevented by using at regular intervals over the beds such kinds of standard plants as will best harmonise with the other plants in the beds, such as, for instance, standard variegated Abutilons in a bed of scarlet Pelargoniums or the Fish-bone Thistle as a centre to a small circle of Lobelias, or standard Fuchsias in beds of dwarf foliaged plants. These examples will suggest others, the only point to be borne in mind in selecting these standards being, as we have said, that they contrast in both colour and habit with the plants forming the groundwork of the bed. Yuccas, Australian Dracenas, Grevilleas, tree Sempervivums, and Acacia Iophantha are all suitable for this purpose. Taking into account the shortness of our summer season and the consequent transitory character of flower gardening when tender plants are used, every effort should be made to do without this section, or at all events to use them as sparingly as possible. Unfortunately, the rich chocolate colour which we get in Coleus, and the bright purple and orange in Alternantheras, are not to be had in hardy plants; hence, if we must have these colours, and they are all but indispensable, we have no choice in the matter. Another consideration to be taken into account when making these arrangements is the appropriation or association of various classes of plants together. There is to our mind such an inexpressible degree of incongruity in mixing, for instance, succulents with any of the ordinary kinds of bedding plants, that one marvels that such an error should ever be perpetrated. Used in moderate proportion to other kinds of bedding plants succulents form an interesting feature in summer flower gardens, but under no circumstances should they be mixed with Pelargoniums, Petunias, &c., but only with nearly allied plants, such as Mesembryanthemums, Kleinias, Echeverias, and Sedums.

GENERAL WORK.—The tying up of plants in mixed herbaceous borders, weeding, and filling

up vacancies in the same, thinning out and planting out annuals and biennials, such as Stocks, Asters, Phloxes, Wallflowers, Pentstemons, Antirrhinums, and Aquilegias, and the planting out of spring bedding plants and those that have been forced for cut flowers are operations all of which must now receive attention. Indoors the principal work is giving abundant space to sub-tropicals, and moving out to sheltered spots all those that can safely be risked out, giving Alternantheras and Coleus full exposure to the atmosphere whenever the weather is favourable, and potting up the last batch of cuttings of Coleus and Iresine.

FRUIT.

PINES.—Now days are getting a nice length and the resting period is comparatively short, early-started Queens may be subjected to a higher temperature than has hitherto been advised, that is, assuming that very early fruit is wanted, and necessity leaves no choice, but it must be understood that express speed is not recommended or approved. To secure the greatest amount of good without doing much harm when plants are kept at 70° on cold nights, 75° when mild, and 95° after closing, they should be plunged with their heads close to the glass; some kind of covering, if only a shading blind, should be placed over the roof at night, and ventilation at this treacherous season should be confined to the apex of the house. If the fermenting beds are in good condition and the plants well plunged, root watering will not be a heavy item, but they must be regularly examined and supplied with a sufficient quantity of good liquid or guano water, and air moisture, so essential to the swelling of the fruit, must be secured by damping the walls, floors, and surface of the bed with the same, pure water being used for dewing the plants with after the house is closed for the day.

SUCCESSIONS that were shifted in March will now be growing freely, and will require careful watering and ventilation to keep them in good condition. A great number of Pine plants are much injured and often ruined by having too much water, by heavy syringing when the slightest dewing over would suffice, and by the barbarous practice of opening the front ventilators on a bright May morning, and so exposing the tender young growths to a cutting draught, when a moist, genial atmosphere would be better secured by keeping them closed and giving more air at the apex of the house. The temperature in this compartment may now range from 60° on cold nights to 68° when mild, and early ventilation, when the pipes are heated, will require attention; when the morning rise reaches 75°, gradually increase the day heat to 85°, and close in time for a temporary rise above these figures, with solar heat and moisture. If plants intended for starting in June have been kept dry and cool, the opposite extreme of heat and moisture will cause the greater part of them to throw up. Bring the soil into a nice growing condition by the use of warm generous liquid and feed the stem roots by forcing a little into the axils of the leaves with the syringe, but guard against excess, and defer overhead syringing until the plants are out of flower. Where hot-water pits are getting crowded and young plants require more room, a good fermenting bed, made of one-third manure and two-thirds Oak leaves with a deep Cucumber frame placed over it, will be found all that can be wished for the rapid propagation and growth of new stock.

FIGS.—The fruit on early forced pot trees now ripening fast will be greatly improved in colour and flavour by full exposure to sun and light, as well as by a more liberal admission of air. The latter condition will naturally tend to a general lowering of the night temperature, which will do no harm provided it does not fall below 60°, and the maximum heat is secured once in twenty-four hours. Keep the trees clear of all useless spray, and pinch the points of strong shoots where there is no room for extension. Never allow the roots to feel the want of water, as, unlike all other fruit trees, the Fig when growing is furnished

with an advancing crop in various stages of growth, which must be kept progressing. Syringe the stems and lower parts of the trees, and damp the floors every day, and after gathering all the fruit that is ripe, as we have previously directed, give the trees a thorough washing and shut up with sun-heat at a temperature of 85° to 90°. Thin the fruit in succession houses, stop or cut outside shoots and lay in leaders. Mulch with good manure, water and syringe copiously, and while ventilating freely through the early part of the day, see that the house is closed in time for solar heat to raise it to 85° on fine afternoons.

VINES.—Where late houses have been brought on in accordance with former directions, all the best winter and early spring kinds may now receive Muscat treatment until after the fruit is set, when 65° to 68° by night, and 80° to 85° by day, with a flush of sun-heat after closing, will keep them well in advance of the season, and allow time for cooler night treatment, by the admission of more air when the Grapes begin to colour. If Hamburgs are not likely to be in flower when shy setters require artificial fertilisation, a good supply of pollen may now be shaken into a box, which must be kept in a dry, warm place until it is wanted for use. Endeavour to keep the work well in hand in midseason house in which the Vines are now making rapid progress. Remove all surplus bunches from free setting kinds, discontinue stopping during the time they are in flower, and take advantage of early morning and dull days for thinning out the berries as soon as those which are properly set show signs of taking the lead. When all the bunches are thinned, give the inside borders a thorough watering with tepid liquid, mulch well with good manure, and encourage robust growth by giving plenty of air through the early part of the day, and by closing with sun-heat and moisture every afternoon. Early Grapes now ripe, or approaching that stage, may have less fire heat than they have hitherto received, but they must have sufficient to keep up a circulation of dry, warm air, and to prevent the temperature from falling much below 60° at night. Gradually reduce moisture, particularly towards night, but damp the walls and floors on fine mornings, and syringe the foliage copiously as the crop is cleared for the twofold purpose of cleansing it from dust and insects, and to induce a fresh break of laterals.

PEACHES AND NECTARINES.—As the fruit in the early house approaches ripening be very particular in the selection of pure soft water for syringing with. Turn aside any leaves which interfere with the free passage of sun and light, and give more air on fine mornings when the roof-lights can be let down without exposing the fruit to drops of rain, which bruise and spoil the delicate skin. Give inside borders the final watering, mulch with some dry non-conducting material, and litter the floors with sweet soft hay. Many people at one time used to suspend nets or canvas under the trees to catch the falling fruit, but, independently of the fact that they spoil every Peach which falls into them, they are always in the way, and unless the fruit is wanted for home use, every Peach and Nectarine should be gathered before they are dead ripe and in danger of rolling off the supports which have been placed under them. When the Peaches begin to soften, maintain a dry, warm atmosphere with a constant circulation of air; retard if necessary by shutting off all fire-heat at night. Never wrench the fruit off the trees with the naked hand, as the slightest pressure produces a bruise, but with a pad of wadding in the left hand gently grasp it near the base, sever the stalk with a pair of Grape scissors, and place it on squares of silver paper spread out in shallow-padded baskets. Remove it to a dry, warm room to ripen, or pack it at once in soft, well-beaten Moss if intended to travel.

In succession houses the growth of wood and fruit is unusually rapid, and as the numerous operations will closely follow each other, let good syringing and copious watering have the first care. If the roots are entirely under glass and the bor-

ders are well drained no one need be afraid of overwatering a healthy-growing tree, provided the water used is clear and its warmth is equal to the mean temperature of the house; neither need they allow it to carry more than a very small percentage of surplus fruit to compensate for dropping. Where the roots are outside the drenching rains we have recently had will have penetrated to the drainage, and all that is now needed is good mulching to keep in moisture and to draw the surface feeders up to the influence of solar heat. Follow up dis-budding, tying down, and thinning in late houses. Syringe well about 6.30 every morning, ventilate abundantly, and ply the syringe again after closing for the day.

MELONS.—As good Melons cannot be expected where the foliage ripens before the fruit, see that the roots are well fed, and the house carefully syringed every afternoon until the most forward show signs of changing for ripening. Plants growing in pots may receive more water as soon as the Melons begin to swell, but if planted on hills, watering should be deferred until they have attained the size of large Walnuts. Carefully preserve all the old leaves, thin out all spray, and support the fruit on small pieces of board before the weight becomes a strain upon the Vines.

Melons in pits and frames cannot have too much sun and light. Ventilate with caution, and close about three o'clock with moisture when the fruit begins to swell. Attend to linings and coverings, as nights will be cold until after midsummer. Earth up successions with strong loam, and prepare fresh beds for successions by the time frames now full of Potatoes or bedding plants can be dispensed with.

STRAWBERRIES.—If good pits are available, get all the best kinds arranged near the glass, with plenty of room between the pots. Ventilate freely, and shut up with strong sun-heat and moisture when the fruit is set. Where extra large fruit of exhibition kinds is desired, thin off all side and inferior blossoms before they open, support with sticks, and give diluted liquid at every watering. Early forced plants that have been hardened off and rooted may be planted out for autumn fruiting. Soak the balls, ram the soil very hard, mulch with rotten manure, and water with the hose in dry weather.

INDOOR PLANTS.

AZALEAS.—These are amongst the most accommodating plants we possess, for with sufficient stock and a suitable selection of kinds that have a natural disposition to bloom early, with others to follow and some that will bear being kept back, there is no difficulty in keeping up a succession from the latter end of the year until the middle of summer, but to do this it is necessary to vary the season of growth, encouraging the plants that bloomed earliest to make and complete their growth correspondingly early. Although this section of Azaleas will make growth and set their buds in an ordinary greenhouse temperature, still when so treated they make slow progress in gaining size, the wood being weak compared with that which is obtainable with a little warmth and a moist atmosphere; moreover, where considerable quantities of these flowers are wanted for cutting there is much gained by keeping them warm, as so managed the season's shoots attain double the length they otherwise would do, and can be used so much longer when cut—an advantage which those who have floral decorations to arrange cannot fail to appreciate. An intermediate temperature, with a moist, moderately confined atmosphere, secured by not giving too much air, and this only for some six or eight hours in the day, is what they like. All hybrids of Indian and Chinese origin take more water at the root, especially whilst they are making growth, than most other hard-wooded plants would bear, and at the same time they ought to be freely syringed daily to keep down thrips and red spider. When those which flowered first have set their buds and got the current season's shoots well matured, they should be removed to a house or pit, where they

can be given a plentiful supply of air, so as to be quite cool. Those that have recently bloomed should at once have the seed vessels picked off, and be treated in every way like those already described.

EPACRISES.—Such of these as after blooming had their shoots cut well back, and have now made some growth, should be moved into pots a size larger, but it is well to bear in mind that none of the varieties can bear so much root room as many things; they are very impatient of the soil getting too wet, a condition that is much more likely to happen in the case of large than in that of small pots; a 2-inch shift is quite enough for any that are already in from 6-inch to 10-inch pots. Epacris will do with peat a little closer in texture than some things; but it must have a liberal addition of sand in it, for if at all of a spongy character, so as to have a tendency to hold water, the roots are sure to perish. Pot hard and do not give water sooner after potting than is absolutely necessary, to avoid which see that the roots are sufficiently moistened before potting. The liability which these plants have to die suddenly when they appear in the best of health and there is no apparent cause is in most cases attributable to too much water at the roots; they need to be allowed to get drier before water is given than Heaths. If the young soft shoots droop slightly previous to its being applied it rarely follows that much harm is done. A slight sprinkling with the syringe on the afternoons of bright days will be an advantage.

CYCLAMENS.—Young stock of these raised from seed sown last summer will now require especial attention. To bloom them well in fifteen or eighteen months after the seed is sown there must be no time lost. The old method of managing these plants with cool greenhouse treatment was slow and unsatisfactory. The best results are obtained by keeping them growing from the time the seed germinates without rest in an intermediate temperature. Now, when the sun has got much power, they must not be fully exposed to it, or they will not grow kindly, the leaves never attaining their full size and being much more susceptible than they otherwise would be to attacks from red spider. See that the soil is kept pretty moist; any that were sown late and not yet removed from the pots or pans in which they were pricked out should at once be put into small pots. Plants that have done flowering should be got together and placed in a pit or house where they can be properly attended to with water; the system of drying them off is altogether opposed to their well-being. Means ought to be taken to keep them free from insects, so as to preserve the old leaves in healthy condition. By this means when the time comes for their pushing up a fresh crop of foliage they will be much more vigorous and bloom again proportionately better.

LAPAGERIAS.—These finest of greenhouse climbing plants are to some extent exceptional in their requirements. If grown in houses where any warmth is used further than is sufficient to keep out frost, they are excited to earlier growth, and under such circumstances I have found the young shoots and leaves very impatient of exposure to the full force of the sun, which not unusually has the effect of stopping the shoots from attaining their full growth, and causing the leaves to be deformed. Any aspect seems to suit these plants better than the south, yet if in too dark a position they rarely flower, however strong they may be, so freely as when more favourably placed in this respect. Now, whilst the young growth is in its tenderest condition, a thin shade of some kind should be applied and the soil should be kept well moistened, especially if the plants are grown in pots or tubs and the roots fully occupy the soil; but where small or medium-sized examples have been recently turned out in beds of considerable extent the earth must not be made too wet, otherwise it will get into a soddened condition, under which the plants do not thrive. Syringe every afternoon, getting the water if pos-

sible well to the undersides of the leaves; if this is attended to regularly, thrips, to which these plants are so subject, will be kept down, an essential point, for though the hard texture of the leaves prevents their being killed outright, still the insects feeding on them shortens their duration—a sad mishap when used for covering back walls and similar places in conservatories, for which purpose *Lapagerias* are well adapted.

HELIOTROPES.—The small examples of these, such as are used for ordinary greenhouse decoration, are well enough in their way, but where quantities of these fragrant flowers are required for cutting late in autumn and during the early months of the year, and the houses are calculated to accommodate them, some large plants should be grown either planted out on a back wall, if such is available, or trained to a pillar, for covering either of which few subjects can be more profitably used, as grown thus they will yield a plentiful supply of flowers. Should the new large white variety, *White Lady*, prove equal in freedom of blooming to the old kind, which has hitherto not been surpassed for general usefulness, it will be an acquisition. Its large size and decided colour commend it for a trial.

HABROTHAMNUS ELEGANS AND CESTRUM AURANTIACUM.—These nearly allied plants do well on the back wall of a conservatory. The *Habrothamnus* is scarcely ever out of bloom, and the *Cestrum* flowers freely for a considerable time in the late summer and autumn. To do them justice they should be planted out, but if there is not room for this, they must have good-sized pots and be regularly supplied with manure water when their roots get full hold of the soil, otherwise the quantity of flowers forthcoming will be proportionately reduced.

PLUMBAGO CAPENSIS.—Few plants are more effective for greenhouse walls or pillars than this; and where it can be planted out so as to allow of its getting strong, it produces abundance of its lovely pale blue flowers for several months at a time. It should be grown in pots until it has attained some strength, or else the soil gets out of condition before sufficient roots exist to take possession of it. For decoration in 6-inch or 7-inch pots this *Plumbago* is an excellent plant. The present is a good time to strike cuttings of it for this purpose as they will get nicely established before autumn.

LARGE-FLOWERED AND FANCY PELARGONIUMS.—It is well to see that plants of these coming into flower are free from aphides; if not, they should be fumigated twice within six or eight days, so as to free them from these pests; for if affected with them when the flowers are expanded and fumigation has to be resorted to then, it will cause the blooms to drop in quantity. These, as well as *Calceolarias* now in flower, should be shaded from the sun, or their flowers will fall quickly. If a few cuttings of *Pelargoniums* are at the present time put in to strike, they will be good plants by the autumn, and will make large bushy specimens before the time of flowering next spring. Such cuttings can generally be obtained from the plants that are about to flower without waiting until the usual time of cutting down after they have done blooming.

ARUM LILIES.—Plants of these that have been forced, especially if large, may now with advantage be split up into single crowns, putting some into pots to be grown on in them and planting the weaker portion out-of-doors. They will do well in ordinary soil in an open situation, and if a shallow trench is prepared for them it will be found to suit them. In this way they are easily kept supplied with water, of which in dry weather they can scarcely have too much; and so treated, they make more compact growth than in pots. In autumn they must be taken up and potted singly. They will flower in succession after the pot-grown examples are over, which latter are best for forcing early.

FUCHSIAS.—If the stock consists of early flowering varieties and others that naturally bloom later, there will be no difficulty in having plants of these in bloom from the present time up

to late in autumn. Those not wanted to come in until considerably later should be no more exposed to the sun than is necessary to keep their growth stout, otherwise it is difficult to get them to grow much, so inclined are they to bloom after this time. Pinching the points once more of the shoots of the later portion of the stock helps to retard the flowering, but the plants so treated must have pots large enough to give them an increase of root room, or they will not bloom strongly. Let the whole stock be frequently well syringed. This is necessary to keep down both aphides and red spider, either of which will much interfere with their growth, as well as with the healthy appearance of the foliage.

DOUVARDIAS.—In whatever way the young plants, struck from cuttings in the winter, are to be grown through the summer, in pots, or planted out in frames, they should be attended to in the way of stopping the shoots to prevent their getting long and straggling, studying the natural habit of the sorts grown; the close-habited *B. Vreelandi* grows bushy naturally. Do not let any small stock of these suffer through confinement of the roots in little pots, as if this happens they get into a stunted state. Where there is a large conservatory to furnish, some of the old plants that have been cut back may with advantage be grown on to a considerable size, as if given plenty of root space, say 12-inch or 13-inch pots, and the points of the shoots pinched in once or twice between this and the end of June, they will make large bushes that will bear a profusion of bloom through the latter part of the summer, at which time independent of their always acceptable flowers, they will help to give variety at a season when blooming greenhouse plants are not plentiful.

KITCHEN GARDEN.

EARLY Potatoes should now be carefully hoed and earthed up at once. It is said by many that when not earthed they are earlier. Should that, however, be so, which we doubt, the large quantity of green-ended tubers occasioned through not being earthed diminishes their value; therefore, we always earth up our Potatoes, and get them early too. Fill up all vacancies in *Seakale* beds. What we use for this purpose are the roots of those taken up for forcing; cut them into 6-inch lengths and place them upright in pans or pots, and fill in with light soil; place them in a cold frame, and every piece will become a plant. Be careful to rub all the eyes away but two. These root cuttings make fine strong plants during the summer. The first fine day go through Onions, Carrots, Parsnips, &c. Our system is to use draw hoes instead of Dutch hoes, walking in one row and hoeing the other. In this way no footmarks are left, and all the weeds lie on the top of the ground; in fact, all hoeing should be done in this manner. Asparagus beds will be greatly benefited by a small sowing of salt on the surface. We never saw salt injure Asparagus after the tops appear. It, however, kills all seedling weeds, and keeps the beds clean for the summer. Scarlet Runners sow now in shallow drills 6 feet apart, and cover with burnt refuse. Early Broccoli may be planted between each row when ready. Dwarf Beans (*Osborn's* and *Canadian Wonder*) may also be sown at once.

THE LATE MR. LEEDS' GARDEN AT LONGFORD BRIDGE.

ABOUT three years ago I first became aware of the existence of an old garden rich in floral treasures within a few miles of my house. A friend told me of a very beautiful *Crocus* he called *C. Leedsi* which he had obtained from an old garden. I was aware of the *Leedsi* Daffodils, but had never heard the story of their origin, and when I now learnt that Mr. Leeds, of Longford, had been the great florist who had raised these new varieties of *Crocuses* and Daffodils, it was not long before I sought out the place. It was on the turnpike road from Manchester to Chester, near the bridge which crosses the Mersey. The event is firmly impressed on my memory. I found a

plain, roomy cottage with extensive outbuildings, quite hidden from the road by huge overgrown and neglected *Rhododendrons*, *Box* and *Laurels*, 15 feet or 20 feet high, with rounded tops and bare hollow centres, between which the pathway to the house threaded, as if through a leafy arbour. It was early spring, and the whole garden was ablaze with Daffodils, growing by thousands almost wild; but still one could trace the old beds, and the gardener had a portion of the ground fairly well kept with long Daffodil beds, where he grew the sorts, as separate as practicable, for sale. There were huge groups of *Pæonies*, and several lovely varieties of *Scilla campanulata*, white, blue, lilac, rose colour, and intermediate shades of each—evidently showing that this beautiful plant had been hybridised, and here it was in clumps a foot through of each sort, quite neglected and growing wild under the orchard trees. To the rear of the house were some old tumble-down greenhouses, and brickwork pits, with unglazed lights, filled with small pots of alpine which had overgrown the place, forming large mats of *Saxifrages* and *Sedums*. The chief treasures in the greenhouses were a lot of seedling *Amaryllises*, which had been grown from seed carefully hybridised by Mr. Leeds, and these are now blooming here, some of the varieties being very beautiful. Beyond the greenhouses were

THE **ROCKERIES**, or rather **brickeries**, where Mr. Leeds had his alpine. There were four of them, each about 100 feet long and 10 feet across, built up of bricks tier upon tier, with spaces between the bricks, each sufficient for a plant. The centres were raised about 3 feet, forming long, narrow mounds, now completely covered over with dense masses of vegetation. In some places the *Veronicas* had gained the ascendancy and covered over everything; at another *Saxifrages* had it. There were large clumps of the most beautiful form of *Orobanchus vernus* I ever saw; several of the hardy *Geraniums* had grown into large masses, and beautiful *Fumarias* formed lovely purple bases. Of the smaller *Irises* there were huge clumps. Creeping plants had strayed over the walks, and on the borders beyond were thickets of large growing sorts—*Telekias*, *Asters*, *Campanulas*, *Delphiniums*, *Heracleums*, *Veratums*, and other giants in rankest growth, the fittest having survived. On closer inspection these rockeries were found to abound with choice treasures, which appeared from season to season, and had to be marked out when in bloom for future removal. The whole was a vast overgrown wilderness, left to grow as Nature willed it, and in a few more years there would probably have been but a few plants left, and these only the rankest growers. Such was the old garden of Mr. Leeds when first I saw it.

On Friday last I went over, as usual, at the close of Daffodil time, to see if any *Narcissi* of value were to be had, and, lo, the place had gone! All the old *Rhododendrons* and *Laurels* had been cut down; the cottage was newly painted up, and had fresh tenants, and it stood boldly out to view from the road as I drove up to the gate. There were three or four spade labourers at work trenching the ground for Potatoes, and a surveyor was laying it out for building plots. All the rockeries were cleared away, the old fruit trees felled, and every trace of this famous garden had departed. During the three years I had never lost sight of this garden and its treasures, and many cartloads of plants had been transferred to Brockhurst. Mr. Wolley Dod had a consignment of the big plants sent to his collection, at Edge Hall; Mr. Barr had purchased all the selected Daffodils at Mr. Leeds' death; but many treasures remained, and amongst these were the bulbs in the two seedling beds where the hybrid *Narcissi* had been raised. All these were carefully removed to Brockhurst, and as I write there are some 1000 blooms of *Narcissi*, unnamed, but many of them as beautiful as some of the best now in Mr. Barr's list. To those who have seen this bank of Daffodils lately, it has been a sight to dwell upon for the whole year. The plants of *Scilla campanulata* have also been removed

here, and form a grand sight in June. It is pleasant thus to have been able to recover this interesting lot of salvage from so grand a wreck.

EDWARD LEEDS was a sharebroker, and died April 4, 1877. For the last six years of his life he was an invalid, and had lost the use of his legs, so that he could only be wheeled about his garden in a bath chair. When a lad at school he had a fancy for flowers, and spent his pocket money in plants, which he bought in Smithydoor Market, in Old Manchester. His father lived in Cheetham Hill, but removed to Longford, where he and his son lived for 42 years, during the whole of which time the garden was kept up with the most loving and careful attention. It was then the meeting ground for our old Lancashire florists. Tulips, Auriculas, Carnations, and Pinks were grown there as hobbies, and the wider cultivation of alpine and herbaceous plants was also pursued with ardour. The late Sir William Hooker, of Kew, corresponded with Mr. Leeds, and the herbarium formed by him was sent to Kew just before he died, and is said to have filled four cases. Mr. Leeds was one of the first to solve the mystery of hybridisation, and was especially successful with the Narcissi. By growing the later blooming sorts in pots under glass he was able to cross them with the earlier ones, and in this way he used *N. poeticus* with *N. incomparabilis*, and the result was the beautiful series of Leedsi Narcissi, the corone of which were thus tintured with scarlet and orange. No more remarkable series have ever been raised, and in Mr. Barr's hand they have met with full development. Two of Mr. Leeds' hybrids have almost been lost, but are now growing here, saved from the wreck of the old garden. *N. major superbus* is a fine yellow trumpet Daffodil, and *N. bicolor maximus*, a late blooming bicolor, with a longer tube than Horsfieldi and Empress, and otherwise nearly equal to those fine Daffodils, with the valuable distinction of coming a fortnight later, evidently showing that they were obtained from the *N. bicolor* of Linnaeus. These were both figured in the *Magazine of Botany*, as were also the two Crocuses above referred to.

WILLIAM BROCKBANK.

Brockhurst, Didsbury.

BOOKS.

INDIAN FERNS.*

THIS excellent book, which is intended to meet a want that has long and acutely been felt by all lovers of Ferns, will be all the more welcome coming, as it does, from an author whose thorough knowledge of the subject is already well known through his former works: "The Ferns of British India" and "The Ferns of Southern India," published in three volumes of large dimensions, and of which this present book is a condensed form with numerous additions, and the rectifications necessitated by the time which has elapsed between the two publications. The whole contents of the above named three volumes, besides the additions, are here offered to the public, which cannot fail to appreciate the single book—an octavo volume of ordinary dimensions. The great amount of care observed in its compilation makes it a most valuable work of reference, especially to non-scientific readers, for in preparing it as many of the technicalities as could be safely dispensed with have been left aside. The most striking feature in it is the careful division of the genera, which are set forth in a most clear and comprehensive manner according not only to the position of the sori, but also in regard to the venation, the habit, and the venation of every separate genus. With a laudable object in view, that of avoiding the inconvenience of double generic names, the sub-genera have been raised to the rank of genera, which are represented by nearly a hundred in a

work comprising within its geographical limits the whole of British India, Ceylon, and the Malay Peninsula. The entire order of Filices is thus divided into six sub-orders. Sub-order 1, Gleicheniaceae comprises only the Gleichenias, its distinctive characters being that the capsules open vertically and are surrounded by a transverse complete ring. Sub-order 2, that of the Polypodiaceae, which is the most extensive, is distinguishable by the capsules being surrounded

Marattia, and Kaulfussia. Sub-order 6, Ophioglossaceae, which closes the nomenclature of Indian Ferns and only comprises the three genera Ophioglossum, Helminthostachys, and Botrychium, has capsules also without a ring, but they are deeply bivalved and open down the side, nearly to the base. The distinctions between the genera are equally evident, and the definitions of them are so exceedingly clear, that through them anyone with a very moderate amount of know-

Actiniopter dichotoma (Forsk.).

by a jointed vertical and elastic ring. It includes twelve tribes and eighty-seven genera, the complete list of which is of too great a length to find place in this notice, but their distinctive characters are plainly shown. In sub-order 3, Osmundaceae, which comprises only the genus *Osmunda*, the capsules are bivalved, opening across the apex, and furnished with a short horizontal ring. Sub-order 4, Schizaceae, has also bivalved capsules, but these open down the sides, and are crowned by a complete operculiform ring, as is noticeable in the genera *Anemia*, *Schizaea*, and *Lygodium*. Sub-order 5, Marattiaceae, is distinguished by the capsules being completely devoid of a ring and opening by a slit down one side or a spore at the apex, as is very perceptible in the genera *Angiopteris*,

ledge of Ferns in general will be able in a remarkably short time to thoroughly understand their classification. The subject is treated very extensively and forms a magnificent volume of nearly 500 pages, illustrated with 300 admirable woodcuts, the value of which may be gleaned from the three specimens which, through the kindness of the publishers, we have been enabled to reproduce.

The first is a remarkably pretty Fern of dwarf habit, which for nearly a quarter of a century has been known by almost every Indian traveller, as well as by all Fern growers at home, under the name of *Actiniopteris radiata*, but which the author, for reasons best known to himself, has here named *Actiniopteris dichotoma*, and described it

* "Handbook to the Ferns of British India, Ceylon, and the Malay Peninsula." By Col. R. H. Beddome, F.L.S. London: W. Thacker & Co.

as follows: "Stipes densely tufted, 2 inches to 6 inches long; fronds like fans, 1 inch to 1½ inches deep, composed of numerous dichotomous segments, which are Rush-like in texture, not more than one-half line broad, the veins few and sub-parallel, with the indistinct mid-rib, the segments of the fertile frond longer than those of the barren one. Found throughout India, especially the peninsula, in dry rocky places, below 3000 feet of elevation." As this plant has often made its ap-

sometimes hair-pointed; stipes about 2 lines long in the sterile, often about 1 inch long in the fertile fronds; fronds dimorphous, the barren ones roundish or obovate, one-half inch to 2 inches long, three-quarters of an inch broad, very thick and fleshy, and when young more or less covered with stellate hairs, the fertile ones 2 inches to 4 inches long, one-eighth inch to one-fourth inch broad; veins immersed, areoles with copious free veinlets; sori in broad continuous marginal lines, often at

appear alive on their arrival, they have up to the present time been a source of torment to those who gathered them, and a source of disappointment as well as a pecuniary loss to whoever speculated on their successful importation. If they could only be imported in a sound and healthy condition, there is very little doubt as to their doing well here, as from accounts gathered from many different travellers they grow very freely and plentifully in their native habitats. Of *S. dichotoma* Colonel Beddome gives a clear, short, and succinct description at page 452, where it is described thus: "Stipes 6 inches to 18 inches long, firm, erect, glossy, channelled on the face above; fronds, fan-like in general outline, 6 inches to 9 inches each way, many times dichotomously forked, the ultimate divisions half an inch to 1 inch broad, with one fertile segment to each, quarter of an inch to half an inch long, the rachis often curved with four to ten close spreading spikes on each side. This plant is found principally in South India, on the western mountains, and in the Malay Peninsula, although not confined only to these two habitats, as it also comes from Tropical America and the West Indies, Australia, New Zealand, Polynesia, Philippines, and Mascareen Islands." These three illustrations, with their accompanying descriptions, which may be taken as a fair sample of the way in which the subject has been treated, will, we think, suffice to show the nature of the work, and cannot fail to convey a pretty correct idea of the amount of exertion gone through by its painstaking author.

Species already in cultivation and those not yet introduced receive at the hands of Colonel Beddome the same careful attention; and although we might make a tolerably long list of the former, we find that there would still be room left for a good selection of Ferns well deserving introduction. Among those of Indian origin already in cultivation we may note: *Acrostichum aureum*, a semi-aquatic Fern of great beauty; *Actinopteris radiata* or *dichotoma*, above referred to; *Adiantum caudatum* and *lunulatum*, both exceedingly useful species adapted for baskets; the very rare *A. venustum* (true), as the one generally found in commerce is nothing more than a dwarf form of *æthiopicum*, differing essentially from the typical *A. venustum*; *Angiopteris evecta*, a semi-aquatic of large dimensions and bold habit; *Asplenium Belangeri*, *caudatum*, *heterocarpum*, *longissimum*, and *formosum*, all species of great merit, and unequalled in their genus for their decorative qualities; *Brainea insignis*, a thoroughly distinct habited Fern, making with age a short thick stem; *Ceratopteris thalictroides*, a very interesting Fern, enjoying thoroughly aquatic treatment; the delightfully pretty *Cheilanthes argentea* and *fragrans*, *Davallia bullata*, *elegans*, *Griffithiana*, the charming little *D. parvula*, the very decorative *polyantha* and *solida* are also among the cultivated species; also the noble *Didymochlena lunulata*, the curious *Drynaria coronans* and *quercifolia*, the very handsome *Goniophlebium lachnopus*, *subauriculatum*, and *verrucosum*, all three very decorative as basket Ferns; the charming *Hymenophyllum Polyanthos*, the rare *Lindsaya cultrata*, and the equally scarce *Lygodium dichotomum*, *Microlepia platyphylla* and *strigosa*, the rare and beautiful *Onychium auratum*, which often makes its appearance in the gardens, but is never plentiful; the equally rare *Osmunda javanica*, the most distinct species of its genus; the highly interesting *Platynerium biforme* and *grande*, *Stenochlæna scandens*, the very remarkable *Trichomanes anceps*, *javanicum*, and the extremely pretty and very rare *T. parvulum*. Many more species from India are to be found in good collections, but the above named are by far the most interesting, and in many cases also the rarest, in cultivation. From the woodcuts of the book, as well as from the dry specimens with which we are acquainted, it is very apparent that many thoroughly good plants may be introduced yet with great advantage, foremost among them being *Adiantum Parishi*, *Schizæa dichotoma*, and *Matonia pectinata*, *Prosaptia contigua*, *Stenoloma chinensis*, *Schizoloma lobata* var. *malabarica*, *Cheilanthes myso-*

Drymoglossum piloselloides (Presl).

pearance in gardens, and as it has in several cases been cultivated with great success, many readers will be able to judge for themselves of the correctness of both the illustration and the description, which in our opinion are most exact.

The subject of our second illustration, *Drymoglossum piloselloides*, is one of those plants which are found in many habitats, in some cases very distant from one another. This, for instance, is a native alike of the Bengal plains, Burmah, Ceylon, South India, in the plains of Malabar, in Java, the Philippines, and Japan, in which places it covers the trunks of trees. The following is Colonel Beddome's description of it: "Rhizome, long, filiform, wiry, clothed with adpressed, diamond-shaped, peltate lacinated scales, which are

length confluent and covering the whole under surface, capsules mixed with a few stellate paraphyses." We are not aware that this species has at any time either been sent or brought home in a living state, as we have never seen it or heard of it being in any collection, but have often seen it among dry specimens.

Schizæa dichotoma, which is here beautifully and accurately illustrated, belongs to sub-order 4, which is distinguished by its bivalve capsules opening down the side, crowned by a complete operculiform ring. The three or four species which form the genus *Schizæa* are all particularly interesting from their peculiar habit, and although it is often sent or brought to this country by collectors, and although in most cases they

rensis, Pteris Griffithi, Asplenium tenuifolium, Dipteris Horsfieldi, Lobbiania, and Wallichii, Lygodium polystachyum, and many others too numerous to be mentioned here. The facilities for the introduction of these plants will be greatly increased by the present work, as it gives the habitats of all of them. We have only to add that the book is printed on good paper and otherwise well got up, and further to express a hope that it may attain the popularity which it well deserves.

S.

KITCHEN GARDEN.

SUMMER LETTUCES.

EVERYONE who has had anything to do with raising and growing of Lettuces knows how difficult it is to get them good during the summer, especially when treated in the ordinary way, that is by sowing them in seed beds and transplanting, a method of treating them that is far from the best. The system I have always pursued, and it is one I can strongly recommend, is sowing the seed in drill rows where the plants are to stand, by doing which much time and labour are saved, and the young Lettuces are left with their tap roots intact. These drive straight down into the earth, and as the plants receive no check they grow very fast, and attain a large size with fine solid hearts that become well blanched, and, as a natural result, are tender, crisp, and juicy when cut up for use in the salad. Transplanted Lettuces are generally the reverse of this, the reason of which is, that they flag through transplanting; and having lost their mainstay (the tap root), they suffer during dry weather, as instead of being able to penetrate deeply into the soil and search for food and moisture below, they are entirely dependent on what they find within their reach above, where the supply often fails. Distressed and checked by sun and drought, the tissues become hardened, and the Lettuces are in consequence tough and indigestible and unfit to eat. The best place to get good Lettuces at this season of the year is on ridges between rows of Celery, as there they have great depth of soil, owing to the addition of that thrown out from the trenches, and as it is principally surface material they have to root in, and as their elevated position affords them plenty of room, light, and air, they are able to reach the fullest stage of development. If the land appears to be at all poor, it is a good plan before digging the trenches for the Celery to scatter a thin layer of rotten manure between, which manure the Lettuces will have to make use of when they begin to turn in. Stimulated by its richness, growth is expedited, and the plants have not that

TENDENCY TO "BOLT" or run to seed which they have when their supply of food fails or runs short. Another reason why Lettuces should be grown between Celery is that by having them there it economises space that could not be utilised for anything else, as other vegetables would be a longer time on the ground; whereas Lettuces reach their full size in a short time, and are off and used before the soil is required for earthing up and bleaching the Celery. To get the land in proper order for sowing, the surface must be finely raked and made level and smooth, when all will be in readiness for drawing the drills. These should be made about an inch deep, and in them the seed should be scattered regularly and thinly, or, better still, dotted in small patches a foot apart, which is the proper distance for the plants to stand when thinned out singly, which they should be as soon as they are large enough for anyone to pick out or distinguish the strongest, and they are the plants to be left. In the event of slugs assailing them, or as a preventive measure, if there are any of these troublesome insects in the garden, it is a good plan to slightly dust the leaves with soot, to get which to stick it is necessary to apply it during early morning while the dew is on the plants; but as soot is of a hot nature, the sowing it must be done with a light hand, or the tender plants will be injured. The best kind of Lettuce to grow for summer use is the old Paris White Cos, which,

cultivated after the manner referred to, is always succulent and good, and hearts in of itself without any tying.

FOR WINTER WORK there are none equal to Hick's Hardy Green Cos and the White-seeded Bath Cos, both of which will stand hard frosts and come in fit for use very early in spring, or by sowing now or soon after this, they will be large enough to cut by the end of October. As there is never any fear of late Lettuces running to flower, or suffering greatly from transplanting, they may be sown in seed beds and dibbled out from these into the ground where they are to stand for the winter. The most suitable situation for them is a warm south border under a wall, as there they get sun and shelter, and what is of equal importance they can have drier soil, which saves them from spot or other disease. Before planting, the border should be well manured and deeply dug, and if at all heavy, have leaf mould worked into it, which will help to keep it open and assist the drainage by allowing the water to pass freely through. To give proper room, the rows should not be nearer each other than 15 inches, and the plants that distance apart in the rows, which will give them room to spread and let the air through. Lettuces that are fully grown by the end of October, if needed for winter, should be lifted and stored in cold frames, where if covered during sharp frosty weather with mats, they may be drawn from when wanted.

S. D.

NOTES ON BROCCOLI.

OF all winter vegetable crops this is the most important, and during the next two months sowing and planting must have special attention. As a rule the seed for our main Broccoli crops is sown the last week in April or the first week in May, but should anything prevent us from sowing them, then we would sow up to the end of May; so if any have not yet put in their Broccoli seed, there is still time to do so. Judging from the many letters I receive containing enquiries about vegetables, I find the idea very general amongst amateurs that in order to secure a long and constant succession of Broccoli, the seeds should be put in at different times, sowing the early ones in spring and the late ones in autumn. It is not, however, through practice of this kind that a constant supply of Broccoli can be kept up from November until May. If some of the early Broccoli seed was sown in February or March, many of the plants would be liable to produce heads prematurely when four or five months old, and if the spring varieties were not sown until August or thereabouts they would fail altogether to give good returns. It is by the selection of varieties that a succession can alone be secured, and if six, eight, or ten sorts are cultivated to give a supply say from the beginning of November until the end of May or middle of June, the whole of the seeds may be sown on the same day. It may be stated, too, that great numbers of varieties are not required for a long and good supply. If it is known that one kind will produce heads satisfactorily during November and December, there is no use in growing other three or four kinds which will come in at the same time. Altogether in recent years we have grown and tested over five dozen kinds of home and Continental origin, and now our sorts are few, but really good. For convenience I will classify them thus: November and December, Veitch's Self-protecting Autumn Broccoli, an excellent sort; January, Snow's Winter White and Backhouse's winter variety; February, Cooling's Matchless; March, Carter's Mammoth Spring White; April, Cattell's Eclipse; May and June, Sutton's Late Queen; the latter, like the first-named, is indeed a queen amongst Broccoli, and should be universally cultivated, as it never disappoints, and it comes in at a time when anything in the way of Broccoli is much valued. In

SOWING THE SEED OF Broccoli any odd corner or strip of border where the soil is fairly good will answer the purpose, as the young plants will only remain in their germinating position until they become large enough for planting in their

permanent places. In forking over the seed ground before sowing we generally add a dressing of leaf soil or old Mushroom bed manure, as we find the young plants make more roots in this than in cow, horse, or rough lumpy manure. For convenience in hoeing between and also to admit plenty of light to the young plants, we prefer sowing the seeds in rows to broadcast, and to carry out this plan drills 2 inches deep and 6 inches or 8 inches apart are opened for its reception. It is sown thinly, the covering over is done carefully, and when finished the soil over the seed is left very smooth. At this season the seed germinates fast; sometimes in humid weather the plants can indeed be seen in the rows a week after sowing, and when in this stage and until they have gained strength, a sharp out-look has to be kept for snails and slugs, which are very fond of the tender young plants and devour them greedily. In damp weather it is therefore necessary to look out for them night and morning, and at the same time dust slightly every other day with soot or powdered lime. In dry weather some may be inclined to water their young Broccoli, but we never do this; artificial watering is not, indeed, wanted when the soil has been properly prepared. As soon as the plants become anything like crowded in the rows, the largest of them are drawn out and dibbled into another piece of ground 3 inches or so apart. Here they soon catch hold of the soil, and make nice bushy plants to be transferred, with a good ball of soil adhering to the roots, to their permanent quarters. Those left in the seed rows have sometimes space enough to remain and be planted out with those dibbled in elsewhere, and in any case those growing in the seed rows are always handy for making up blanks or for forming later plantations on ground which may not be vacant at the general planting time. In reference to this, I may say

THE TIME TO PLANT is not fixed by a hard and fast rule, but may extend from the beginning of June until the end of July. When the ground is empty and plants early, they may be put out at any time, but in our case the ground is hardly ever empty or waiting for them, as we have often to keep the Broccoli plants growing in the nursery beds until they are upwards of 1 foot high before the ground for their reception is cleared from other crops, such as Peas, Potatoes, &c. In dealing with large, or what may be termed overgrown, plants, a little more care is needed in transplanting than in the case of small, young material, and in July, when the weather and soil are generally excessively dry, newly-planted Broccoli is much benefited by a thorough watering. Besides, the ground which will become vacant for Broccoli two months hence we have a good deal of space ready for them now; but this is not idle, empty ground, as Potatoes have been planted on it with a distance of 3 feet from row to row, and immediately these are earthed up the Broccoli will be planted between each row. As the Potatoes develop the stems will be kept from smothering up the Broccoli, and when the tubers are lifted the soil will be spread out and levelled down around the Broccoli stems, and by September our quarters will contain as promising a crop of Broccoli as they do at the present time that of Potatoes. In planting autumn Broccoli, a distance of 2 feet from plant to plant each way will give good results, but winter kinds will be benefited by being planted wider apart, as they cannot be grown too hardy or well exposed, and 2½ feet or 3 feet should be given them. Deeply-cultivated ground will always produce the finest crops, but excessive manuring should be avoided, as this forces the plants to make soft, succulent growth in autumn, which is very liable to be injured in winter.

Margam, Glamorganshire.

J. MUIR.

Potato sets.—Will "A. D." be so good as tell me where I can lay my hands on any records that "fully demonstrate that crops are great or less just as the sets are large or small" where the sets in each case have been disbudbed to an equal number of their strongest buds? I am quite well aware that the largest sets produce the

heaviest crops, because, as I have already explained, they have most eyes. But, if Robert Thompson is right, big Potatoes should produce heavier crops than small Potatoes, bud for bud, for the reason, according to him, that the buds are stronger on the former than on the latter. But do they? I say they do not, because as a rule the buds—within certain limits as regards size of tuber—are just as strong on the small Potato as on the large one. This is the point; the rest follows as a matter of course either way.—J. S. W.

LATE PEAS.

"J. C. F." (p. 363) and Mr. Sheppard (p. 408) do not believe in early Peas for late sowing; neither do I. They are too tender and do not fill their pods satisfactorily in September and October, and they are not worth growing for a supply at that season when placed against some of our real good late sorts. I do not regard *Ne Plus Ultra* in the light in which it is looked upon by some. In my opinion it is neither the best, the second best, nor the third best of the many fine Peas in cultivation. As an early Pea it is nowhere; as a second early or main crop variety, it has no unequalled points; but as a late variety, I would term it one of the sorts worth growing. It is a prolific Pea at the points of the shoots, but I have never yet seen it clothed with pods from the ground upwards like some kinds that could be named. It is a very straggling grower, and in a wet autumn or in very rich ground the straw often becomes 8 feet high; large stakes, seldom obtainable by the majority of growers, are therefore required to support it, and unless these can be used, the growths double over, and this hinders the pods from forming and filling freely. Of all late Peas, I know of none equal to *Laxton's Omega* as regards general usefulness. As a rule it grows 3 feet high; it is very robust and hardy, bears most prolifically from the ground upwards; the pods fill up well late in the season, and the flavour is all that could be desired. It is altogether a Pea better adapted and more worthy of general culture as a late sort than any other kind I could name. With us it is almost useless to sow late Peas after the first week in June, as later ones do not yield remunerative returns, and we are very particular in giving the late crops a rich soil and a sunny position.—J. MUIR, *Margam, Glamorganshire*.

I have not one word to say against *Ne Plus Ultra* and the *British Queen*, recommended by "J. S." for a late crop, but I should like to suggest that he should also grow *Bruce Findlay*, a new variety sent out for the first time this season. It was sent to me for trial two years ago, and I shall be surprised if it does not take a high position as a late Pea.—J. C. CLARKE.

GARDEN DESTROYERS.

BIRDS V. SLUGS AND SNAILS.

We all know that blackbirds and thrushes destroy many shell-snails in times of frost, or of dry, parching weather when worms are scarce, but I scarcely thank them when they tear to pieces a choice *Saxifrage* in pursuit of their prey. As to slugs, I never knew any small bird to touch them; and with regard to ducks, which are generally credited with a special appetite for such food, I do not know that my ducks are more dainty than others; they certainly pretend to be very eager in ferreting slugs out in the long grass, but when I have thrown a few in the midst of them, the onslaught seems rather one of rivalry than of preference; a few are eaten and the rest left in disgust. Even a glow-worm, I believe, distinguishes between the snail and the slug, rejecting the latter. I was not until recently aware that tame pigeons gave us any aid in our gardens. I knew that they did some mischief, not as a rule picking off the leaves and flowers so much as the seeds. Though they find the flower of the *Aponogeton* and the leaves of the *Eschscholtzia* too tempting to resist, they do not, however, injure in the same manner as ducks, whose wide, heavy feet and inquisitive bills disfigure all they touch. Then the

aid of which I speak is very great. It is true they will not touch the slugs, but in a single morning a pigeon will pick up from 50 to 100 shell-snails varying in size from a pea to a small marble. The benefit is really incalculable.—T. H. ARCHER-HIND, *South Devon*.

— Allow me to add my experience in reference to birds eating slugs. Last spring my attention was directed to a female thrush or mavis whose beak was filled to overflowing with small black slugs, evidently destined for her nestlings. Since then I have closely observed these birds, and though I have never seen them eat slugs, yet during their breeding season, in spring, I have repeatedly watched them gathering mouthfuls of small slugs. I am, therefore, inclined to think that slugs form no part of the regular food of the parent thrush, but that they feed their young with them. Like all old gardens, this is infested with slugs, and though surrounded by woods, and visited by scores of blackbirds and thrushes, they do not appreciably diminish the number of slugs, constant warfare with lime and soot alone enabling us to get seedling vegetables through their infancy. Our best friends as slug destroyers are a few pairs of domestic pigeons, which, I am told, are Jacobins. Until quite recently I was incredulous as to pigeons eating slugs, but actual observation has convinced me of the fact. Observing that these birds made it a morning practice to alight in the garden, and feeling curious to know what food they sought, I paid particular attention to them. They are very tame, and time after time I have stood within a couple of yards of them and seen them busily clearing a Strawberry quarter of slugs. In that part of the garden, too, which they frequent there is a marked diminution in the number of slugs. So useful are these pretty birds and so welcome, that we are careful to avoid frightening them in any way. I cannot say that I have seen blackbirds either eat or gather slugs, though I have watched them as closely as their shy nature will allow. I am, however, so convinced that the friendly services of these birds and thrushes so much outweigh any loss which we sustain in the way of their eating fruit, that I should be sorry now to repeat the youthful practices in which I was encouraged and rewarded, viz., searching out and ruthlessly destroying every nest found within the pleasure grounds.—A. MOORE, *Cranmore*.

— I can corroborate Professor Owen's assertion that thrushes eat slugs, though the proof that they do so may be more difficult to bring forward than that they eat snails—a fact of which every observer is aware. I think, however, that the following is pretty strong evidence of their slug-eating powers. In 1881 a thrush built its nest in a Juniper close to my house. She had young ones, and at the moment I chanced to pass was engaged in feeding them. At the same instant I perceived that my cat had climbed up the tree, and was preparing to spring upon the old bird. I succeeded in catching her and rescuing the thrush, after which I examined the brood, and found one apparently dying. Much interested, I endeavoured to discover the cause of its trouble, and after a little time saw it proceeded from some large substance in its throat, which by great efforts it at last succeeded in dislodging, and which proved to be a large brown slug—not a snail. Up to this time I had never had positive proof that any living creature—not even the much-praised duck—could eat slugs, but this was certainly incontrovertible.—CHARLES NOBLE, *Bagshot*.

— Notwithstanding the opinion of Canon Elcombe of Bitton and the Rev. Wolley Dod, I could not help thinking that some direct evidence might be forthcoming to show that blackbirds and thrushes do feed upon slugs; at any rate let us credit them with this great service till we are sure of the reverse. As Mr. Dod says, the stomachs of three or four blackbirds where no slugs have been found is only negative evidence after all; but what will he make of the following note which I have just now had from the Rev. F. O. Morris, rector of Nunburnholme (the author of "British Birds") about this point? His words are these: "I have never dissected any birds myself, but I feel

sure Mr. Macgillivray, who dissected, as a surgeon, every bird that he could for his most accurate 'British Birds,' states that the blackbird and the thrush both make slugs part of their food. They are for the most part hidden from sight in the daytime, but I feel confident that they would devour all slugs they meet with, and be glad to get them."—X. Y. Z.

PRESERVING TIMBER.

THE processes of creosoting and kyanising—the two operations, according to the *British Architect*, largely carried on by the firm of Armstrong, Addison & Co., of Sunderland—are founded on the possibility of filling the pores of timber with a preserving liquid which, by a very complete saturation of the timber, affords sound protection against decay. Some have attempted to preserve timber by steeping it in creosote oil, but they have found that, whilst the outside was preserved, the heart decayed. Others have merely brushed the surface over with the preservative, but of course the result has been a failure. The course adopted in creosoting by the firm in question is as follows: The timber is placed in iron cylinders of great strength; little trams are specially built to run into these cylinders ready loaded, rails being fixed along the inside of them; swing doors are swung to and securely fastened by strong iron cramps, and the cylinders are ready for the commencement of the process. This consists in extracting the air from the cylinders, and also from the pores of the wood, which is done by means of a vacuum pump. Then it is only necessary to admit the creosoting liquid, which is forced into the wood by a force pump under a maximum pressure of about 150 lbs. to a square inch. This work must be conscientiously and carefully executed. First of all, the timber must be thoroughly dry, or the moisture will simply be driven into it, and, being unable to escape, will inevitably cause decay. Then the creosote oil must be of good quality, and there must be no meanness in supplying a sufficient quantity of it. There should never be less than two-thirds to one gallon of oil forced into each cubic foot of the wood, and in cases where the scantling is small, and has consequently a larger amount of exposed surface, even more than this is requisite to due preservation.

KYANISING wood which has to be subsequently painted over, and also for situations where there is especial danger from fire, is also a process to which much attention is paid. It consists in forcing into the wood a solution of corrosive sublimate, and is a more costly matter than creosoting. The kind of timber to be used is of course a matter of importance in giving full effect to the preservative processes employed. Telegraph poles suggest a large destruction in Swedish and Norwegian forests. The sleepers used by English railway companies come chiefly from Russia and Prussia. Some engineers give a preference to Scotch Fir sleepers, which, when thoroughly creosoted, become as durable as any wood that has been fairly tested. American white Fir sleepers were laid on the line from Manchester to Crewe in 1838, and a few years since were as sound as ever, and Scotch Fir sleepers, laid on the North-Eastern line in 1851, were taken up in twenty-seven years (1878) in a perfectly sound state.

The claims of creosote as a preservative are, that it prevents the growth of any vegetation, *i.e.*, the propagation of fungus, and completely hinders the absorption of moisture into the wood. Not only does creosote prevent decay, but it repels the attacks of marine worms. For estate purposes the importance of creosoting is being felt more and more every year; owners find they can have at a small cost a fence that will not decay. Creosoted wood pavement was first laid down in Sunderland in 1867. The Corporation permitted a strip of creosoted Redwood and one of creosoted Beech to be laid across the roadway of the Wear Bridge; although a heavy traffic has passed over these for fifteen years they are still sound. The surface of the Redwood is rather uneven, but the Beech is practically as good as ever. When

measured by the Corporation in 1879, the average wear of the Redwood during twelve years was found to have been 15-16ths of an inch, and of the Beech only 3-8ths of an inch—less, in fact, than some granite setts laid down four years later. The wood paving, as laid down by Messrs. Armstrong, is as follows: A concrete bed is laid over the road formation, properly graded; the wood blocks are laid in a thin bed of sand at the top of this, and they measure 6 inches deep, are 3 inches to 3½ inches wide, and 6 inches to 12 inches long; the joints are run with asphalt and small gravel in proper proportions. By means of a machine specially designed for pavement work four blocks are cut at once. Redwood blocks from Memel, Dantzic, or Stettin timber are said to be more durable than those from Swedish wood.

SOCIETIES.

MANCHESTER ROYAL BOTANICAL AND HORTICULTURAL SOCIETY.

MAY 11 TO 18.

THE annual Whitsuntide show held by this society was opened on the 11th. On this occasion an important feature was the handsome roomy exhibition building recently completed to take the place of the old structure which has so long done duty for the accommodation of the more tender productions at these annual gatherings, and which has unmistakably had no small influence in creating the wide-spread taste for displays of this kind that exists in Manchester and the surrounding districts, as proved by the vast crowds that each year attend these exhibitions. The new building is considerably larger than the old one, being some 25 feet long by 54 feet wide, and it is well adapted for the purpose intended, having ample heating accommodation. The greater portion of the plants, in fact all except those at the back furthest from the eye, are arranged on the floor level, a way in which it is needless to say they are seen to better advantage than they otherwise could be. There was a slight falling off this year in one or two of the leading classes for Orchids and large flowering hard-wooded plants, consequent on the absence of several exhibitors who have before been contributors. And no doubt to some extent the severe weather experienced during the whole of the spring has also had an influence in retarding the blooming of many things ordinarily in flower at this time; the effect of this was to be seen in several departments, notably in that of hardy herbaceous plants, many of which gave signs of having been kept warmer than is desirable in order to bring them into bloom. Orchids, as usual here, were well shown both as to size and condition. In the amateurs' class for fifteen, Mr. Holmes, gardener to O. Schneider, Esq., was first, and Mr. G. Swan, gardener to W. Leech, Esq., second. In the class of nine Orchids Mr. Mitchell, gardener to Dr. Ainsworth, was first, with large well-grown, and finely-bloomed plants; and in the class of six Orchids, Mr. Goodall, gardener to Mrs. Leech, was first, his best examples being *Dendrobium nobile*, *Cattleya Mossiae*, and the old, but effective, *Oncidium sphacelatum*. A class exists here for Orchids not made up; any collection shown with a plant put together to increase its size, in the way so often practised, would be disqualified. In this class Mr. Holmes was first, and Dr. Hodgkinson second. In the nurserymen's class for sixteen Mr. James, Castle Nursery, Lower Norwood, took the lead with a medium-sized, nicely bloomed collection, Mr. Cypher, Cheltenham, being second. Other nurserymen's classes were also well sustained. Stove and greenhouse flowering plants were not quite equal to what they usually are here, most of the collections containing some very good and others inferior ones. Mr. Cypher took the lead in the nurserymen's class. Mr. Paul, gardener to S. Schloss, Esq., Bowdon, was first among amateurs. Fine foliaged plants were contributed in large quantities and in good condition by Mr. Cypher and others. Dra-

cænas were contributed by Messrs. F. Ker & Sons, of Liverpool, who had twelve plants alike remarkable for their size and the magnificent colour of their foliage. Of Roses, Messrs. Paul & Son, Cheshunt, had a fine group of medium-sized plants, well flowered, and in their way more beautiful than larger specimens. Mr. J. Hooley, of Stockport, also showed some well bloomed plants, showing that even in the smoky neighbourhood of this manufacturing town Roses

Mr. Cypher was likewise first with eight Azaleas, medium sized plants well clothed with large flowers. With Pelargoniums, Mr. C. Ryland, Ormskirk, was first.

New plants were shown by Mr. B. S. Williams, Holloway, who staged, amongst others, *Selaginella grandis*, the finest of all the Lycopodiums; *Nepenthes Mastersiana*, *Aralia Kerchoveana*, *Davallia fœniculacea*, a grand new Fern not yet in commerce; *Aralia Chabrieri*, *A. undulata*, Dra-

Nº 278.

Schizra dichotoma (see page 453).

can be fairly well grown. Nothing in the exhibition was more attractive than the large groups of plants staged for effect. In the amateurs' division Mr. Smith had a beautiful collection, noteworthy alike for cultivation and the effective way in which the plants were arranged. Mr. Paul, who was second, also had a very pretty group, in which were a couple of dense, bushy plants of a fine form of the white *Marguerite* about 4 feet in diameter, and so profusely flowered as to almost hide the foliage. In the nurserymen's class for groups of a like description Messrs. Ker were first with plants well chosen and skilfully arranged. Cape Heaths were nicely shown by Mr. Cypher and the Liverpool Horticultural Company, the latter having an evenly flowered half-dozen.

cæna Lindeni, *Croton Excelsior*, and *Dalebachia rupestris*. Messrs. Ker furnished *Anthurium splendidum*, *Selaginella grandis*, *Croton Nieumani*, *Ficus elastica albo-variegata*, a fine and distinctly variegated plant, likely to become a popular favourite; and a hardy double white Azalea named *alba plena odorata*, a variety of great promise, a decided advance over everything in its way we have seen. Mr. James had *Panax Veitchii*, *Selaginella involvens variegata* and *Cymbidium Devonianum*. Amaryllises were shown in fine condition by Mr. B. S. Williams, who also had some good Pitcher plants, and so had Mr. Entwistle, gardener to J. Broome, Esq., and Mr. Paul, the latter having several large pans of *Sarracenia purpurea* bearing the largest pitchers that have

come under our notice, and a beautiful example of *Cephalotus follicularis*.

HARDY HERBACEOUS PLANTS were well represented, Mr. Entwistle being first with a group in which were *Trillium grandiflorum*, *Lychnis Viscaria*, *Antirrhinum Liliastrium*, *Funkia ovata*, *F. Sieboldiana*, and *Thalictrum purpurascens*. Mr. Entwistle was also awarded a first prize for thirty alpine, well grown and nicely shown. In the nurserymen's class for sixty herbaceous and bulbous plants the first prize went to Messrs. Dickson and Sons, Chester, whose plants were beautifully grown and nicely grouped; second, Mr. Brownhill, who also had a good collection, in it being a remarkably handsome form of *Primula intermedia* named *purpurata*. Forty alpine came from Messrs. Dickson and Sons, who showed among others *Saxifraga muscoides atropurpurea*, *S. lantoscana*, *S. pyramidalis*, *S. Wallacei*, *Corydalis nobilis*, *Primula intermedia*, *Delphinium nudicaule*, *Viola pedata alba*, and others of equal merit; second, Mr. Brownhill, who likewise had an even group.

CUT FLOWERS.—These came from Mr. Cypher, the only exhibitor. Bouquets were beautifully shown, artistically arranged, and not too large. Three equal first prizes were awarded to Mr. Cypher and Mr. J. Mason, Manchester. Both colour and materials in Mr. Cypher's examples were alike faultless, the charming *Pancreatium fragrans* being conspicuous in each. Mr. Mason's three were mostly composed of yellow, red, and pink Roses, with a little *Stephanotis* and *Gardenia intermedia*. Second, Mr. G. Foster, Stretford, and third, Mr. C. Wilson, Kendal, both staging handsome arrangements. The prizes in the amateurs' class for two bouquets went to Mr. Elphinstone, gardener to Mr. J. Heywood, Mr. R. P. Gill, Ashton-on-Mersey, and Miss Johnson, Ascot, in the order in which their names stand. A fine group of Orchid flowers was staged by Messrs. Thomson & Ireland, Craigleith Nursery, Edinburgh, comprising some fifty species, in which were beautiful spikes of *Vanda suavis*, *V. insignis*, *V. tricolor*; *Odontoglossum crispum*, *O. Pescatorei*, *O. vexillarium*, *O. Andersonianum*, *O. Roezli*, *Laelia purpurata*, *Cymbidium Lowianum*, *Cypripedium caudatum*, *C. laevigatum*, *C. Lowi*, *C. villosum*, *Dendrobium thyrsiflorum*, several varieties of *Masdevallia*, and others; with these were some flowers of *Anthurium Scherzerianum*, the largest we have met with. It should be added that a large miscellaneous collection of flowering and other plants was shown by the Liverpool Horticultural Company, including most of the popular species and varieties of hard and soft-wooded stove and greenhouse plants.

FRUIT.—Mr. McIndoe, gardener to Sir J. W. Pease, Hutton Hall, Guisborough, was the only competitor in the class of eight dishes. They consisted of Black Hamburg and early Frontignan Grapes; Lord Napier Nectarines, very fine; Bellegarde, Barrington, and Royal George Peaches; President Strawberries; and McIndoe's Scarlet Premier Melon, all in nice condition. Two bunches black Grapes—for these Mr. McIndoe was easily first with well finished examples of Black Hamburg; and Mr. Bruce, gardener to Mrs. Ackers, Congleton, second. Two bunches of white Grapes—First, Mr. McIndoe, who showed early summer Frontignan; second, Mr. J. Fildes. Two Pines—First, Mr. Bailie, gardener to the Earl of Wilton; second, Mr. Bruce. Single Pine—First, Mr. Goodacre, gardener to the Earl of Harrington; second, Mr. Bailie.

Messrs. J. Waterer & Son, Bagshot, received the Society's gold medal for a very fine collection of Rhododendrons and hardy shrubs, comprising a large and varied group of the best evergreen species and varieties. Messrs. Rodeer, McClelland, & Co., of Newry, had an extra prize for a group of hardy plants in flower consisting of about a hundred species and varieties in beautiful condition.

Extensive collections of miscellaneous plants not for competition were contributed by Mr. B. S. Williams, whose exhibit contained Orchids, Palms, Amaryllis, Ferns, Crotons, Dracenas, &c.; Messrs. F. and A. Dickson, Chester; Messrs. Ker, and Mr.

Cypher, all of whom had varied and interesting groups. From Messrs. Cutbush & Sons, of Highgate and Barnet, came a very complete collection of hard-wooded plants, including most of the best spring-flowering Heaths and New Holland and Cape species, a large proportion of which were in bloom; these were intermixed with Palms, Dracenas, and others of like description, collectively having a nice effect.

ROYAL BOTANIC.

MAY 16.

THE first summer show of the season held in the Regent's Park Garden on Wednesday last, was considered to be decidedly below the average of corresponding shows of recent years as regards the quality of the exhibits. Taken collectively, too, it was singularly destitute of interest, there being comparatively few real novelties and no new departure in any direction. The same old plants were arranged in the same stereotyped manner, though there was no lack of brightness; in fact, we thought the *tout ensemble* of the tent too glaring, a matter which might have been improved by bringing into view the groups of foliage plants hidden in the recesses, and setting back some of the garish Azaleas always masses of unrelieved colour. Every projecting bank was a mass of blossom. We should like to see the practice discontinued of placing a long straight row of pyramid Azaleas on the crest of the Orchid bank, thus utterly destroying the effect of the quieter colours of the Orchids, which, instead of brilliantly toned Azaleas or other showy plants, should have a background of elegant foliage, with which the delicate hues of the Orchids would harmonise. With the exception of these little drawbacks, the show was attractive as regards effect, and the subdued light of the tent lent an additional charm to the gay colours. The classes in which there was a conspicuous falling off in quality were those for Orchids, Ferns, fine-foliaged plants, and hardy plants; but, on the other hand, stove and greenhouse plants were well represented. Azaleas have rarely been better, and the same may be said of Pelargoniums, Roses, and Clematises.

NEW PLANTS were rather numerous, and, as usual, there were large numbers considered worthy of certificates.

BOTANICAL CERTIFICATES were awarded to

DAVALIA BRACHYCARPA.—An extremely elegant Fern, with long recurved finely divided fronds reminding one of *Asplenium Fabianum*. It is one of the choicest of the cultivated Hare's-foot Ferns. Shown by Messrs. Veitch, Chelsea, who introduced it from the New Hebrides.

WORMIA BURBIDGEI.—A Bornean shrub of erect growth, with noble foliage and bearing large, clear yellow flowers on short racemes from the upper part of the stem. Introduced by the exhibitors, Messrs. Veitch, from Borneo.

BEGONIA GOGOENSIS.—Remarkable for the rich velvety tones of the shield-shaped leaves, which measure about 6 inches across. They are vinous purple on their under surfaces, and of various shades of green on the upper sides. Messrs. Veitch.

ACANTHOPHIPPIUM CURTISI.—An Orchid more curious than beautiful. It has large plicate leaves like those of a *Phaius*. The flowers, borne in loose clusters on short stems, are a reddish purple and curiously shaped. Messrs. Veitch.

CATTLEYA IRICOLOR.—A very distinct species, having flowers about the size of those of *C. Skinneri*. The sepals and petals are creamy white, as is also the labellum, which has a yellow throat and a band of carmine near the margin. It is a pretty Orchid, though not so showy as some of its congeners now in bloom. Messrs. Veitch.

CYPRIPEDIUM RECURVIPETALUM.—A new species in the way of *C. Veitchi*, but differing in having a larger pouched lip, deflexed petals more profusely and minutely spotted, and by the dorsal sepal being rather larger than in *C. Veitchi*, and edged with creamy white, as in *C. Mastersianum*. In foliage it is not much different from *C. Veitchi*. Messrs. Veitch.

OCHNA MULTIFLORA.—A curious and elegant ornamental stove shrub of neat growth, and remarkable for its bright red and green fruits and yellow flowers borne on the plant at the same time. Mr. B. S. Williams.

EPIDENDRUM FREDERICI GUILIELMI.—A rare species belonging to that section of the genus, having tall leafy stems terminated by a loose cluster of blossoms. In this species the flowers are larger than usual and of a dark rose-pink. Mr. Williams.

MAXILLARIA LUTEO-ALBA.—A handsome Orchid having large flowers, the sepals of which are arranged in a triangular outline. Their colour is a brownish yellow tipped with white, rendering it distinct from other species. Mr. Williams.

CALADIUM LUDEMANNI, with large leaves, having a rich pea-green ground, copiously blotched with pure white and reddish crimson, making the plant extremely ornamental; **CARDINALE**, ground colour reddish pink, traversed by veins of a deeper hue, and, moreover, semi-transparent; **ORNATUM**, a kind with deep green leaves, veined and streaked with rich crimson-red; and **VERDI**, with leaves wholly of a deep rich red except a broad margin of emerald-green. All these were exhibited by Messrs. Laing & Co, Stanstead Park Nurseries, Forest Hill, and comprise the choicest new varieties.

IMPATIENS SULTANI.—A new Balsam from Zanzibar, bearing a profusion of rich carmine flowers on neat habited plants. It will doubtless become a popular plant for affording winter and spring bloom. Messrs. Veitch.

PRUNUS PISSARDI.—A new variety of Plum, remarkable for the coppery purple tinge of its foliage, which resembles that of the ordinary Plum in size and form. It is a very ornamental deciduous tree, and will, no doubt, become popular. It was exhibited by Messrs. Laing under the name of *P. Pichardi*.

DENDROBIUM LEUCOLOPHOTUM.—A very pretty species and distinct from most others. From its tall pseudo-bulbs it bears long racemes of blossoms on slender stalks springing at right angles from the bulb. The flowers are pure white, much resembling those of *D. barbatulum*. Messrs. Veitch.

FLORICULTURAL CERTIFICATES were awarded to

AZALEA MADAME VAN HOUTTE, a variety of *A. indica*, having large single flowers of a salmon-pink colour, edged with white. Exhibited by Mr. Turner, Slough.

AMARYLLIS STAR OF INDIA.—A splendid variety with flowers of large size and perfect form, and of a brilliant carmine-crimson. One of the finest of the twenty-two that have been certificated from Messrs. Veitch's nursery this season.

COLEUS CANARY BIRD.—A neat growing sort with small leaves of a pale yellow prettily edged with green. It is quite out of the ordinary run of Coleuses. Shown by Messrs. Laing.

AZALEA BARON N. DE ROTHSCCHILD.—A variety of *A. indica* with large double flowers of a bright reddish purple, abundantly produced, and *A. Souvenir de Prince Napoleon*, a single variety with flowers of a rich salmon tint edged with white, distinct from and superior to others of a similar colour. Shown by Messrs. Veitch.

AURICULAS WILLIAM COOMBER, RESPLENDENS, RICHARD GORTON, OUIDA, ROB ROY.—All alpine varieties, having yellow centres and richly shaded grounds mostly of a maroon-crimson, and perfection as regards size of flower, symmetry of outline, constitution, and other points that constitute a perfect alpine Auricula. Shown by the raiser, Mr. Turner, Slough.

ROSE MERVEILLE DE LYON.—A Hybrid Perpetual with large and full flowers, almost a pure white, there being but the faintest suggestion of a blush tint in the petals. It is undoubtedly one that will have a bright future. From Messrs. Paul & Son, Cheshunt.

BEGONIAS (double tuberous) LITTLE GEM, large flowers, pure white; **CANARY BIRD**, flowers perfectly rosette-like, of a sulphur-yellow; **PRINCE OF**

WALES, SIR GARNET, CLARINDA, all with large flowers, perfectly double, and of various brilliant shades of vermilion; and DR DUKE, with enormous large double flowers of a bright scarlet-vermilion. These represent the finest double Begonias that have yet been raised. Exhibited by Messrs. Laing & Co., Forest Hill.

ORCHIDS.—We were sorry to see such a perceptible falling off in the numbers of these beautiful plants, which usually form such an attractive feature at these summer shows, the "Orchid bank" being almost bare. This was particularly noticeable in the amateurs' class, which as a rule is well represented, and by such celebrated connoisseurs as Sir Trevor Lawrence. There was but one collection of a dozen plants. This came from Mr. Southgate's garden at Streatham, and was admirably shown by his gardener, Mr. Salter. This group was a very creditable one, and among the most prominent were *Dendrobium nobile*, a fine specimen, 3 feet or more through, and densely flowered, particularly having regard to the late date; *D. Wardianum*, also a large well-flowered plant; *D. thyrsiflorum*, with six large drooping spikes; *D. Jamesianum*, a huge potful; *Masdevallia Harryana*, with some scores of flowers; *Oncidium concolor*, with seven fine spikes; the rare *Cœlogyne elata*; a splendid variety of *Cattleya Mendeli*, with four blossoms; another of *C. Warneri*, *Odontoglossum Ruckerianum*, *O. citrosmum*, and *Vanda suavis*. The two collections of twelve from nurserymen were from Mr. James, Lower Norwood, and Messrs. Jackson, Kingston. Mr. James' first collection included some choice things, such as *Lælia Schilleriana* and well grown specimens of *Cypripedium Stonei*, with five spikes; *Burlingtonia fragrans*, well flowered; *Dendrobium Jamesianum*, *Cattleya Mossiae*, and *C. Mendeli*. These with small, full, well-flowered specimens of *Dendrobium fimbriatum*, *D. nobile*, *Lælia purpurata*, and *Odontoglossum vexillarium* were among the other prominent plants in this group. In Messrs. Jackson's collection was a plant of the rarely seen *Schomburgkia tibicinis*, the Cow's-horn Orchid of Honduras. The flowers, borne on a cluster terminating a long slender stem, are something like those of *Vanda teres* in colour, but are smaller, and the sepals are wavy. Other conspicuous plants in this group was a *bona-fide* specimen of *Masdevallia Harryana*, with several dozen flowers rising from a fine healthy tuft of foliage; *M. ignea coccinea* was also good, likewise *Oncidium ampliatum majus*, *Odontoglossum triumphans*, and *Saccolabium guttatum*.

STOVE AND GREENHOUSE PLANTS were shown as usual in perfection both by nurseryman and amateurs, but there was but little novelty among them, and habitual visitors could probably recognise the majority of the huge specimens shown. Among nurserymen Messrs. Jackson were invincible, as they generally are. Their collection of a dozen plants was a grand one. The most noteworthy plants were *Rhododendron Countess of Haddington*, profusely flowered; *Hedera fuchsoides* and *H. Tulipifera*, both the pink of perfection in every respect; *Erica Webbiana*, *Lindleyana*, *Cavendishi* were likewise grand examples, and also *Aphelexis macrantha*, *rosea*, and *purpurea*. These, with *Dracophyllum gracile*, a monster *Azalea* or two, and a superb specimen of *Anthurium Scherzerianum*, made up a fine dozen. The second best dozen came from Mr. Tudgey, who hitherto has shown among amateurs, but is now a nurseryman at Waltham Cross. His group was excellent also, and contained marvellous examples of *Anthurium Scherzerianum*, a huge specimen profusely flowered and in perfect health, and representing a good variety; *Erica ventricosa magnifica*, 5 feet through, *E. Cavendishi*, and smaller, but excellent plants of such varieties as *Aphelexis macrantha*, *Hedera rosea*, *Azaleas*, and *Clerodendron Balfourii*. In Messrs. Peed's group was a plant of the pretty *Boronia pinnata*.

The amateurs' stove and greenhouse plants were scarcely inferior to the nurserymen's. The best ten were from Mr. Spode's garden near Rugeley. It contained a grand specimen of *Tremandra ericæfolia*, the best we have ever seen, being some

5 feet through, and completely smothered with its small purple flowers. Other notable plants were the difficultly-managed *Acrophyllum venosum*, *Dracophyllum gracile*, *Erica depressa major*, and *E. affinis*, both monster plants, dense masses of yellow flowers, *Statice profusa*, *Hedera Tulipifera*, *Ixora Williamsi* and *coccinea*, and a plant of *Anthurium Scherzerianum*. Mr. Spode's gardener (Mr. Chapman) also showed the finest half-a-dozen plants which were as noteworthy for excellent culture as his larger collection. He had in it another superb plant of the pretty *Tremandra* and a huge *Anthurium Scherzerianum*, with a profusion of spathes; *Ixora Dixiana* and *coccinea*, and a large dense bush of *Erica Cavendishi*. The second best group of six, from Mr. Rann, Handcross Park, contained a wonderfully fine specimen of *Dendrobium nobile*, a dense mass of bloom; *Erica Lindleyana*, and *Aphelexis macrantha rosea*, both well grown. Heaths were admirably shown by Messrs. Jackson, who make such a speciality of hard-wooded plants and always show so finely. The six plants shown were *Erica ventricosa coccinea minor*, as perfect as could be; *E. ventricosa magnifica*, *E. depressa*, *E. Cavendishi*, *E. Lindleyana*, and a seedling of the gummy-flowered section of a bright red colour.

THE CLEMATISES from Messrs. Jackman, the only exhibitors, were perhaps the most beautiful feature in the show, and one that attracted more attention than any other. Every plant was a grand specimen, 4 feet or 5 feet high, and profusely flowered. The selection of varieties were, among white and light-tinted sorts, *Mad. Van Houtte*, *Gloire de St. Julien*, *Languinosa candida*, *Henryi*, *Fairy Queen*, *Duchess of Edinburgh*, with lovely white rosettes. The purples and blue included *Mrs. Hope*, *Lawsoniana*, *Blue Gem*, *Duke of Norfolk*, *Lady C. Nevill*, *Sensation*, and *Purpurea elegans*. This was as fine a dozen as could possibly be chosen. The plants occupied a sloping bank in an isolated group, and in such a position produced a fine effect, and one uncommon at flower shows.

THE ROSES from the Cheshunt Nursery were magnificent, and, of course, were a centre of attraction. In the class for nine Messrs. Paul showed some gigantic specimens, all in superb condition. A plant of the pale yellow *Céline Forestier* could not have been far short of 9 feet in diameter and 6 feet high, and thickly studded with bloom. The other plants were *Edouard Morren*, *Anna Alexieff*, *Madame Victor Verdier*, *Charles Lawson*, *Madame de St. Joseph*, *Camille Bernardin*, *Comtesse de Serenye*, *Marquise de Castellane*, and *Beauty of Waltham*. This fine group occupied one of the projecting mounds, where it could be seen to advantage. A collection of twenty plants from Mr. Turner, Slough, were models of what small plants in 8-inch pots should be; they were in rude health and superbly flowered. The most conspicuous sorts were *La France*, *Marie Baumann*, *Mons. E. Y. Teas*, *Marie Van Houtte*, *Star of Waltham*, *Mad. Margottin*, *Charles Darwin*, *Miss Hassard*, and *Innocente Pirola*. Amateurs do not seem to care for growing pot Roses for exhibition, for the class provided for them was not represented, and there was only one other collection of nine plants from nurserymen, but these were poor. A grand display of cut blooms was contributed by Messrs. Wm. Paul & Son, Waltham Cross, and proved a source of attraction. Every bloom was of good quality, and the selection was excellent. *Baroness Rothschild* was as fine as outdoors in July; likewise *La France*, *Dr. André*, *Charles Lefebvre*, *François Michelin*, the new Queen of Queens, *Solfaterra*, *Captain Christy*, *Rêve d'Or*, and *Mad. Levet*. This collection comprised some twenty boxfuls; each contained some two dozen trusses, and a silver medal was appropriately awarded to the exhibitors.

FINE FOLIAGED PLANTS were on the whole not so well represented as is usual at these shows, though a grand group of six was shown by Mr. Rann for the first prize in the amateurs' class. The plants were quite up to the usual standard of excellence, Mr. Rann's plants being of gigantic proportions and in vigorous health. They were *Areca sapida*, *Latania borbonica*, *Cycas revoluta*, *Croton Hendersoni* 6 feet through and well coloured, *C.*

interruptus similarly fine, and a grand plant of *Gleichenia Mendeli*. Some uncommonly well grown Palms were the next best group, from Lady Goldsmid's garden, and in the third group were also some fair specimens of Palms and Crotons. Among nurserymen there was not a brisk competition, there being but three collections. The best came from Mr. Tudgey, and contained a well specimen of *Pritchardia pacifica*, one of the noblest of Palms; *Thrinax elegantissima*, *Cocos Weddelliana*, and *Cycas circinalis*. The Ferns were not nearly so fine as usual, and a third-rate group of six was first on this occasion. It included two *Alsophilas* and a fair plant of *Davallia Mooreana*. A large plant of the pretty *Davallia bullata* and a good plant of the elegant *Adiantum Williamsi*, one of the best of the Maiden-hair Ferns, were among the others.

PELARGONIUMS were shown well by the two great cultivators of these flowers, Mr. Turner and Mr. Little's gardener (Mr. Wiggins). Those from Slough were very fine. In the collection of six were such superb sorts as *Viscount*, *Digby Grand*, *Illuminator*, *Modesty*, *Venus*, and *Sappho*; and the equally fine six from Mr. Little included *Isabel*, *Prince Leopold*, *Jeannette*, *Miss Bradshaw*, *Duchess of Bedford*, and *Digby Grand*. The fancy varieties were likewise shown admirably by these two exhibitors. The best six, from Mr. Turner, included *Miss Porter*, *Mrs. Hart*, *Helen Beck*, *Thomas King*, *Fanny Gair*, and *Princess Teck*, an excellent half a dozen for exhibition. Mr. Little's plants included, amongst others, good specimens of *Roi des Fantaisies*, *Duchess of Edinburgh*, *Lucy*, and *Mrs. Hart*.

AZALEAS were numerous and gave colour to the exhibition, and on the whole were well represented. The chief prize-winner was Mr. Turner, who in the class for six plants had a grand group, all huge specimens, profusely flowered. The sorts were *Chelsoni*, *Duc de Nassau*, *Reine des Fleurs*, *Madame Cannart d'Hamale*, and *Etendard de Flandre*, all superb varieties. The best collection of twelve plants, in 12-inch pots, was also from Mr. Turner, and the plants he showed were perfection, and the selection of sorts was good. It included *Apollon*, perhaps the best of all the single whites; *Roi de Holland*, *Duchesse de Nassau*, *Ferdinand Kegeljan*, *Cordon Bleu*, *Jean Vervaene*, *Mons. Thibaut*, and *Mrs. Turner*, most all single sorts and representative as regards colour. Mr. Child, of Garbrand Hall, was the chief prize-taker among amateurs, and he certainly had a marvellously fine half-a-dozen huge pyramids smothered with bloom. The sorts were *Iveryana*, *Criterion*, *Concinnia*, *Duchesse de Nassau*, and *Model*, the pretty and distinct colours of which combined to make an attractive group.

HARDY PLANTS were only represented by one collection—that from Messrs. Carter. These were chiefly mossy Saxifrages, *Aubrietias*, *Phloxes*, and *Iberises*. Exhibitors seem to overlook such lovely things as the *Gentians*—*G. acaulis*, *G. verna*, for example, the alpine *Dianthus*es, the alpine *Silenes*, alpine *Lynchnis*es, alpine *Forget-me-nots*, alpine *Primroses*, *Anemones*, alpine *Cheiranthus*, alpine *Poppies*, and many others all in flower now, and which, if grown and presented in perfection at these shows, would create quite a sensation. But it seems as if we shall never see the beauties of the alpine flora at a flower show—we see weedy plants instead.

THE MISCELLANEOUS CLASS was a numerous one. A large silver medal was awarded to Mr. B. S. Williams for an extensive group of plants which occupied one of the central banks in the tent. It consisted mainly of fine foliaged plants interspersed with flowering Orchids, chiefly *Cattleyas*, *Vandas*, *Dendrobiums*, *Odontoglossums*, and *Masdevallias*, and other bright flowering plants, such as *Amaryllises*, *Azaleas*, all tastefully arranged. A silver medal was also taken by Messrs. Cutbush and Son, Highgate, for a large group of plants, consisting for the most part of New Holland plants, the speciality of the firm, and which are grown to perfection. *Boronia elatior*, *Tetarrhena verticillata*, *Azalea mollis*, and various Heaths were prominent features in the group.

Another central group consisted of a large and bright array of *Azalea mollis* and *Rhododendrons* from Messrs. Lane, Berkhamstead, who were awarded a silver medal. The fourth central group was one from Messrs. Laing, Forest Hill, which was comprised of Palms, Ferns, Crotons, *Dracænas*, *Caladiums*, enlivened by numerous double and single *Begonias*, *Azaleas*, *Heaths*, the whole admirably arranged in a bold effective group, one that was much admired. A large silver medal was awarded to the exhibitors. Mr. Turner took a large bronze medal for a fine collection of alpine *Auriculas*, chiefly seedlings; and Messrs. Carter & Co., High Holborn, were awarded a silver medal for a very numerous collection of seedling *Dracænas*, among which were some of exceptional merit, but hardly in condition to show their true character. *Calceolarias* were numerous shown. A splendid collection was shown by Messrs. Carter, and smaller ones by Messrs. Cannell, Swanley; Messrs. Dobson, Isleworth, to each of whom a bronze medal was awarded. An effectively arranged group of plants from Captain Patton's garden was a much admired feature, it being distinct from anything else in the show, and Mr. Young, the gardener, was deservedly awarded a large silver medal. We could wish that such groups were encouraged at these shows, for they are effective and interesting. Messrs. Paul, Cheshunt, showed a large basketful of Bromeliaceous plants, which also formed a distinct feature in the show, and, moreover, quite an uncommon exhibit. The formal growth of the Bromeliads was in a measure relieved by a few plants of the feathery *Asparagus plumosus*.

A list of awards is given in our advertising columns.

ORCHIDS.

A flaked *Cattleya Mossiæ* flower has been sent to us by Messrs. Thomson, of Clovenfords, distinct from any we have hitherto seen. The flower is of the largest size, with broad sepals and a wide, shallow and frilled edged labellum. The ground colour is a deep rosy purple, conspicuously streaked and flaked with white, giving the flower a singular appearance.

Special prize for Orchids.—At the summer show at South Kensington, next Tuesday, the prize of £10, offered by Sir Trevor Lawrence for twelve plants of distinct species, will be competed for. The plants must be all *bona-fide* specimens, and any made-up plants will disqualify the collection in which it is shown.

Highly coloured *Odontoglossum Pescatorei*.—At Messrs. Veitch's nursery, Chelsea, we saw the other day a spike of an exceptionally fine variety of *Odontoglossum Pescatorei*, from Mr. H. Powell, Drinkstone Park, Bury St. Edmunds. With the exception of the unique variety *Veitchianum*, in the possession of Baron Schroder, we have never seen such a richly marked form of *O. Pescatorei* as this. The flowers were of fair size and well formed as regards breadth of substance of the petals and sepals, which were pure white heavily marked with large irregular blotches of purplish crimson, while their exterior surfaces were deeply flushed with the same hue. There seems no limit to the variation or these *Odontoglossums*, for we constantly meet with new forms, but rarely such handsome ones as this.

***Masdevallia bella*.**—An uncommonly fine bloom of this strangely beautiful Orchid has been sent to us by Messrs. Thomson, Tweed Vineyard, Clovenfords. It measures 12 inches across the long outspread tails. The high colouring of the flower, moreover, marks it as no ordinary variety, and the open, pure white labellum serves as a contrast to the intensely deep crimson blotches of the triangular formed perianth.

***Masdevallia cucullata*.**—This extremely rare species may now be seen in flower in Messrs. Shuttleworth & Carder's nursery, Park Road, Clapham, by whom it has recently been introduced from South America. Its habit of growth and foliage much resembles that of *M. macrura*, but the flowers are quite different. They are solitary, borne on

stalks overtopping the foliage, and have narrow attenuated sepals 2 inches or 3 inches in length, and of a shining blackish purple. Owing to its sombre tint, Mr. Shuttleworth tells us that it has received the name of "Widow flower" from the natives of New Granada.

Varieties of *Odontoglossum vexillarium*.—Among some forms of this lovely Orchid sent us by Mr. Fowler, Ashgrove, Pontypool, are two which represent the extremes of variation as regards colour in the flowers of this species. One is identical with that shown last week by Sir Trevor Lawrence under the name of *albicans*, and which received a first-class certificate. The flowers are large and almost pure white. In contrast with this Mr. Fowler sends an exceptionally dark variety with flowers of a deep rosy violet tint, the deepest we have seen. Every intermediate shade between these extremes exists in this *Odontoglossum*, but it would not be wise to attach names to each.

Sale of Orchids.—Last week the collection of Orchids formed by the late Lord Egerton, of Tatton, was disposed of at Stevens's Rooms, King Street, Covent Garden. There were some 350 lots, and the total amount realised amounted to above £650. The following were among the highest-priced plants: Three plants of the true autumn-flowering *Cattleya labiata* fetched respectively 15 guineas, 13½ guineas, and 12½ guineas; a fine specimen of the rare *Vanda Lowi*, with three breaks and twenty leaves, fetched 50 guineas. Six plants of the lovely *Lælia anceps Dawsoni* realised good prices; one with five strong bulbs fetched 25 guineas, two others with six bulbs each 13½ guineas and 14 guineas, two more with five bulbs each 15 guineas and 12 guineas, and two good plants 16 guineas. A grand plant of *Masdevallia Harryana* with 200 leaves fetched 15 guineas; *Odontoglossum nævium majus*, 15 guineas; *Cattleya Dominii*, 10½ guineas; *Odontoglossum Edwardi*, 10½ guineas.

The Orchid collection at Selborne, near Streatham Hill Station, belonging to Mr. Southgate, always contains some plants of an interesting character in bloom; but just now the flowering season is at its height, and the various houses are quite gay, particularly those in which the *Odontoglossums*, *Masdevallias*, *Cattleyas*, and *Cypripediums* are placed. Among the *Masdevallias* we noted small plants of the charming *M. Shuttleworthi* fairly bristling with flowers, and the same may be said of the gayly-tinted *M. Harryana*, *Lindeni*, and *Veitchi*, which contrast strikingly with the quieter tones of the *Odontoglossums*, likewise crowded with flower-spikes, particularly *crispum*. Never before have we seen *Masdevallia Chimara* so well bloomed as here; on a comparatively small plant, growing in a suspended boat-shaped trellis basket, there are no fewer than sixteen flowers, most of them fully expanded, weird-looking, and strange in appearance. Others of the same section are also remarkable for their vigorous health. In all cases they are grown in an intermediate house in boat-shaped trellis baskets suspended close beneath the roof. Along with these *Masdevallias* is the rare *Cœlogyne elata* in flower, a plant with tall evergreen foliage, amidst which are produced slender stems carrying crowded spikes of pure white blossoms about 1½ inches across. *Warcewiczella discolor*, with violet-purple flowers, and *Maxillaria nigrescens*, with flowers of a blackish crimson colour, were also noteworthy. In a warmer house we observed an exceptionally strong plant of the uncommon *Cœlogyne Massangeana*, a species bearing a dense drooping raceme of blossoms upwards of a foot in length. The flowers individually have white sepals and petals and a bronzy tinted labellum. It makes an admirable basket plant and companion to the *Phalenopsis*, of which several were in bloom, one of the most noteworthy being the ever-flowering *Luddemanniana*. Among *Cypripediums* (evidently favourites with Mr. Southgate) the somewhat rare *C. Druryi* was in bloom. It is a species in the way of *C. insigne*, and a native of Further India. The foliage has much the same character as that of *C. insigne*, but the colour and markings of the

flower partake more of the character of *C. villosum*, and, as in that species, the petals have the dark medial line running through each, and the flowers, too, shine as if varnished.

***Sobralia macrantha*.**—A magnificent flower of this Orchid has been sent to us by Mr. Peacock, Sudbury House, Hammersmith. It is remarkable for its unusual size and brilliancy of colour—a rich rosy purple. The lip measured between 3 inches and 4 inches in width, and the entire flower upwards of 6 inches in length. Mr. Peacock certainly possesses a wonderfully fine variety of this *Sobralia*.

***Vanda teres*.**—One of the most interesting exhibits at the Regent's Park Show on Wednesday last was a boxful of plants of this lovely Indian Orchid from Sir Nathaniel Rothschild's garden at Tring Park. The plants, numbering some ten or a dozen, were planted in a long box about 9 inches in depth filled with light Orchid compost and surfaced with green Moss. The plants were about a yard in height, and each bore from the upper part of the stem a raceme of large flowers of a beautiful deep rose colour. A cultural certificate was awarded to Mr. Hill, the gardener, who seems to be particularly successful with this class of Orchids, for not long since he first flowered the rare *V. Hookeriana*, another of the cylindrical leaved *Vandas*. From the Tring Park collection there was also shown a flowering specimen of the pure white variety of *Cattleya Skinneri*, one of the loveliest of all Orchids, and as yet extremely rare in cultivation. It bore two fine spikes, and the plant had the appearance of being in vigorous health.

FRUIT GARDEN.

Coverings for Vine borders.—Theoretically "J. S. W." (p. 403) may be right in reference to flagstones on Vine borders not generating heat, but from a practical point of view the result is the same as if they did, as I could show him were he here. Even a wooden plank placed on a Vine border will attract roots to the surface. I do not, however, advocate covering Vine borders with any kind of material—whether it be a generator of heat or not—except in the case of narrow borders, and where the subsoil is of a cold, unkindly character.—J. C. C.

Black Prince Strawberry.—This variety is of much longer standing than even Mr. Sheppard (see p. 403) claims for it. It was raised over fifty years ago by a market gardener at Strawberry Bank, in Aberdeenshire, and sent out under the name of Black Seedling; afterwards it appeared in Edinburgh as Malcolm's Seedling. Through Mr. Kay, of Norwood Hill, it reached the neighbourhood of London, and got into the hands of the late Mr. Outhill, who again sent it out as the Black Prince. Being interested in Strawberry culture, when up at the great exhibition of 1851 I visited Chiswick and paid special attention to the Strawberry marked Black Prince which I had known as Black Seedling about fifteen years before, and I found both to be the same. This Strawberry I still grow, and find it to be my best and only kind.—R. FARQUHAR, *Fyvie Castle*.

Origin of the Blenheim Orange Apple.—We find the following note, by Prof. Westwood, on the origin of the Blenheim Orange Apple, in the *Gardeners' Chronicle* (xviii., 142): "Mr. George Kempster, tailor, who resided at Old Woodstock, and died there September 15, 1773, was the first grower of the Blenheim Orange Apple. When a young man, he observed a plant growing close to the wall of a house, and, liking its appearance, he removed it into a flower-pot, where it became so large that he transplanted it into the garden. In due time it produced two Apples, which proved remarkably fine. The tree continued to thrive and bore fruit regularly, one year its produce amounting to 21 bushels. Every one was desirous of possessing a Kempster's 'Ippin', as it was at first called; and such was the eagerness to obtain grafts, that large branches were repeatedly torn

off in the night time. In 1811, Mr. Whitman, the Duke of Marlborough's gardener, prevailed on his Grace to allow them a place on his table, and the Duke highly approving of them, they have since obtained the name of the Blenheim Orange. In 1820, Mr. Cook, fruiterer in Covent Garden Market, sold a bushel of them for 14s., they being before this period unknown in the market. The original tree was standing in 1826. On September 21, 1822, five of these Apples gathered in the garden of Mr. Farrow, of Woodstock, weighed as follows:—No. 1, 1 pound $\frac{1}{2}$ ounce; No. 2, 1 pound $\frac{5}{8}$ ounces; No. 3, 15 ounces; No. 4, 1 pound; No. 5, 1 pound; total, 5 pounds $4\frac{3}{8}$ ounces; when first gathered their total was 88 $\frac{1}{2}$ ounces. They were exhibited at the October meeting of the horticultural Society, where the Banksian silver medal was awarded for them. In the same year Mr. Griffin, surgeon, of Deddington, gathered one of these Apples weighing 24 ounces. Of the largest of these a model in wax was made, which is now (1882) in my possession."

NOTES OF THE WEEK.

APPOINTMENTS FOR THE WEEK.

May 19.—Crystal Palace: Great Summer Show.

22 and 23.—South Kensington: Great Summer Show of the Royal Horticultural Society; Meeting of Fruit and Floral Committees.

25.—Exeter: Show of Devon and Exeter Horticultural Society.

PRIZES FOR MELONS.—The competition for the prizes offered by Messrs. Carter, High Holborn, for the best fruits of their Blenheim Orange and Emerald Melons will take place at the meeting of the Royal Horticultural Society at South Kensington on May 22.

LIBRARY OF THE LATE M. DECAISNE.—We learn that the sale of the library of the late M. Decaisne, the celebrated French botanist, will take place in Paris at 28, Rue des Bons-Enfants, from Monday, the 4th, to Saturday, 23rd of June next. The catalogue enumerates 3264 lots of books on botany, horticulture, floriculture, agriculture, natural and physical sciences, and miscellaneous works in nearly all the European languages. Copies of the catalogue can be obtained of M. Labitte, 4, Rue de Lille, Paris.

AMONGST THE FLORAL DECORATORS at the opening ceremony of the International Fisheries Exhibition on Saturday last we may mention the following as having taken part, viz.: Mr. B. S. Williams and the General Horticultural Company (J. Wills), who each exhibited fine groups of tall Palms and foliaged plants to the right and left of the dais, the dais itself being furnished with magnificent groups of Roses, Rhododendrons, and Azaleas, from the nurseries of Messrs. H. Lane & Son, Berkhamstead, who, we understand, will maintain a continuous supply throughout the season. At the other end of the long gallery, Mr. James Aldous, Gloucester Road, exhibited two fine groups of plants put up in his usual tasteful style, which will remain throughout the season.

VARIETIES OF RHUBARB.—In exhibiting a collection of the different kinds of Rhubarb at South Kensington the other day, Mr. Barron was hopeful that he might thus do something to clear up that superfluous nomenclature with which even such a common plant has become encumbered. I fear, however, that little is to be hoped for in that direction, and the blame must be laid upon the shoulders of some of the trade who send out as new kinds those which have been in commerce for years and universally grown. There does not seem to be above four really distinct garden kinds in cultivation if we put aside an old green stemmed pointed-leaved kind, the only good one ere the present superior sorts were raised. We find, for instance, that the kind so widely grown for market work at once the earliest and best of all, and known originally as the Early Red, has some twelve or more aliases, including Johnson's St. Martin, Crimson Perfection, and others. This comes in

very early, has tallish, richly coloured stems of a moderate size, is of good flavour, and all round the best table variety which we have. The Champagne seems to be identical with the old Early Lionneus, and is small as compared with the Early Red. It might very well be allowed to drop out of cultivation. Then there remain the Victoria, which also has been sent to Chiswick as St. Martin's, and under several other names, and the huge green-stemmed kind known as Stott's Monarch. This latter seems to have no desirable feature, the size of the stems rendering it too large for ordinary use, and such huge stems are always less tender than the smaller kinds. The Victoria is a valuable late Rhubarb and very productive. The stalks are long, straight, rich in colour, and handsome, and the sort is better fitted for poor soil than the Early Red, because there it is early and produces good moderate sized stalks. If our gardens are amply supplied with the Early Red and the Victoria, we want no more in the way of good Rhubarb.—A. D.

OPEN-AIR VEGETATION in the Royal Botanic Garden, Edinburgh.—Mr. Lindsay reports that during the early part of April vegetation made fairly good progress; westerly winds were prevalent until the 19th, when a change occurred. A succession of cold east and north-east winds had prevailed since that date, which, along with a small amount of rainfall—a most unusual occurrence for April—had been the means of retarding outdoor vegetation considerably. On the rock garden 108 species and varieties of alpine and dwarf herbaceous plants came into flower during the month, making a total of 193 since January 1; while at the same date last year 286 species were recorded as having flowered, showing that this season is still a fortnight at least later than last. With the present month no improvement in the character of the weather has taken place, but the reverse—east winds, occasional showers of hail and sleet, and on the 6th inst. 7° of frost were registered, which has done great injury to many plants. Those which have suffered most as yet are Roses, Dielytra, Astilbe, and Spirea palmata. The young fronds of Osmunda and Athyrium, which were well advanced, are completely blackened and destroyed. Even some species of Thorns have had their leaves browned.

Lawn mowers.—Last year I made careful trials with a 14-inch Excelsior machine against two others of the old type of 18 inches and 30 inches respectively, both by the same maker, and I find that the Excelsior is by far the best mower, except as regards time, when brought into competition with the 30-inch horse machine. In mowing our lawn I find that the time of one man is wholly saved since I dispensed with the horse machine. Two men used to do the work with the 18-inch mower in three days, while now with the small Excelsior, one man does the same work in precisely the same time. This results no doubt from the superior handiness and easy working of the machine. The work which takes the 30-inch horse machine 3 $\frac{1}{2}$ or 4 days to perform, is done by the 14-inch Excelsior in 15 $\frac{1}{2}$ days, the result being a saving of three shillings. Cost of horse machine for 3 $\frac{1}{2}$ days, £2 4s. 4d.; cost of Excelsior for 15 $\frac{1}{2}$ days, £2 1s. 4d.; in favour of Excelsior, 3s. The work of the Excelsior appears as good as that of the others, and it has the advantage that it cuts long Grass. I find that it cuts Grass averaging 6 inches in length fairly well, but I must say this length is rather too much for it, the machine appearing likely to become strained if kept at it. I observed that at the Manchester trials the Invincible had the highest number of marks, and if it is superior in the proportion there indicated it must be a wonderful machine indeed. I want to have the experience of someone who has had both the Invincible and Excelsior at work together for a considerable time. I may add that the Excelsior was constantly at work here during the whole of last season, and at the end of it the knives only required sharpening, work which can be done at

home, I think, by an intelligent man; at any rate I shall have it tried.—R. IRWIN LYNCH, *Botanic Garden, Cambridge.*

—I repeat that if "An Old Lawn Mower" will communicate with me, I will arrange with him as to a trial of the Excelsior mower. I should like indeed to see a thoroughly representative trial of lawn mowers at some place open to the general public. If, therefore, makers or vendors of lawn mowers of all makes will communicate with me as under, not later than June 1, I will endeavour to arrange for such a trial.—W. J. MAY, *Walton-on-Thames.*

OBITUARY.

THE LATE MR. ADOLPHUS STRAUCH.—Mr. Meehan has sent us a circular announcing the death of Mr. Strauch, late superintendent of the Spring Grove Cemetery, Cincinnati. Elected superintendent in 1854, in his thirty-second year, he would have reached his sixty-first birthday on the 30th of August next. Mr. Strauch originated the landscape system for cemeteries, gradually developed its important details, and demonstrated its superiority so clearly that it has been generally adopted, and become the type of many others which have been established in America within the last ten years. It was clearly the creation of genius, a rare genius, but an eminently practical one, made successful by his great industry, tact, and personal popularity. The execution of his plans required years of patient labour, but he lived to see the work accomplished and the cemetery spoken of with pride as the sylvan park of the living as well as the dead, now perhaps the most important possession of the people of Cincinnati. The more private relations which he occupied to the employes of the Association were a sure test of his character. They were honourable, friendly, and durable. To his children he leaves the heritage of genius and the legacy of a good name, to be honoured both at home and abroad.

Tar-varnished pipes.—Allow me to thank your correspondents for their kind advice. Turpentine was the medium that helped me, and by its aid I am nearly out of my difficulty.—SUBSCRIBER, *Maldon.*

Hose-in-hose Cowslip.—I send you a flower of this plant, believing it to be rare, if not new. It was found in a meadow near Lyme Regis.—J. M. [A curious form of the Cowslip, having the calyx almost of the same texture and colour as the corolla. We have not seen it before.]

Exhibits at the Agricultural Hall.—In our comments on these (p. 416) we inadvertently omitted to mention those furnished by Messrs. Richardson, of Darlington. They consisted of a garden frame of improved construction, also their Parisian greenhouse hind, a wall-tree protector, their patent hooded boiler, and models of various houses, and other things of interest to gardeners.

Names of plants.—*G. Bishop.*—*Lastrea quinqueangulata.*—*Ireland & Thomson.*—*Ixia maculata.*—*R. Jeal.*—*Eupatorium ageratoides.*—*M. Peters.*—The Anemones are double varieties of *A. coronaria*, but we know no distinctive names for each of them.—*Subscriber.*—1, *Anemone nemorosa* fl.-pl.; 2, *Narcissus poeticus*; 3, *N. biflorus*; 5, *Muscari racemosum*; 6, *Symphytum tuberosum.*—*S. E.*—*Dendrobium crystallinum*—*A. K.*—1, *Cypripedium parviflorum*; 2, *Orchis Simia* (Monkey Orchis); 3, *Symphytum caucasicum.*—*West Highlands.*—*Saxifraga oppositifolia.*

"This is an ArtWhich does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.***FLORISTS AND THEIR FLOWERS.**

TO THE EDITOR OF THE GARDEN.

SIR,—Referring to the note by "M. R." (p. 444), I wish to say a few words. He asks me, "Cannot I admire garden Primroses without disparaging florists' Auriculas." My answer is, that as the florists by their rules and ways have helped to take the beautiful and hardy Auricula out of the category of garden flowers—they give me no chance. The Primrose, in all its splendid range of colour for the outdoor garden is little grown compared with what it deserves. But the Auricula is a noble flower for the open air, easily grown, and with a fine variety of form and colour never seen on the exhibition bench at all. It is hardy everywhere, and there is scarcely a garden it is not fitted to adorn; yet few know this, and to a great extent it is because of the feeble products of the pip men. I call them "pip men" because they confine their attention mainly to the pip, and, taking a very narrow view of its form and colour, appear to pay no attention at all to such all-important qualities as hardiness, vigour, freedom, and duration of bloom as tested in the open air. I yield to none in admiration for these men, but see a world of loveliness from the same mountain flower of which they (the pip men) take no notice, though it is of infinitely greater importance for the embellishment of our gardens. An exhibitor at the Auricula show told me the flower, even in its stronger and not fine-bred forms, could not be well grown out-of-doors—a piece of nonsense! To-day I spent an hour or two among many hundred strong plants raised and grown in the open air, amazed at their glory and variety of rich, as well as delicate, colours. Cutting away plants of colours I did not desire, some of them had rootstocks like Turnips, showing their strength and freedom in the open air. The colours could be thrown into nearly twenty groups; the forms, too, might be classified, some of them in their rich fringes, quite out of the range of what one sees at shows. To increase the finer varieties of these, so that the garden artist can use each in a group or colouring, is the next step, and so treated an idea might be gathered of the rare value of the flowers for the open garden. It seems to me no question of argument this, but one of fact, that the way of arranging these florists' flower shows does harm. It is proved in this case by the almost total absence of the Auricula in a well-grown state from our open gardens, although it is as valuable for them as any flower in cultivation. Surely a society devoted to the culture of a flower does its work very imperfectly if it only narrows our view of that flower and its capacities. As to the boasted perfection of form, the educated artist, who is best fitted (from the human standpoint at least) to judge of form, usually tells us the forms chosen by the "brethren" are bad. But were they not, and were the kinds and pips they set their hearts on the finest in form, why should we allow them to limit Nature's abounding variety and beauty by setting up their limited notions only as those we are to be led by in our use and study of this noble flower?

While they exclude charming forms and colours, the variety they do allow is sometimes in the direction of the monstrous. What is a "green-edged" Auricula but a monstrosity? A society for the advancement of our knowledge of this flower might fill our gardens with a world of beauty now unknown to them without interfering in any way with what I call the "hard-shell" florist, meaning by that name the narrow school. Individuals will, I hope, succeed in doing so. I know one that will try. When we ask for bread, the florists give us a stone. Let us leave them happy among their pots and pips and monstrous and delicate creatures that so often die off (so we read and hear notwithstanding all the care and greenhouse and frame coddling) and see what we can do without them. J. M.

ORCHIDS.**THE HOME OF LÆLIA ELEGANS.**

THE following account of collecting *Lælia elegans* from its native habitat has been sent to us by Mr. Jens Sand, plant collector for Mr. Lourenço Hoyer, of Rio de Janeiro, and as the identical plants spoken of are in London at the present time, and will be sold by Messrs. Protheroe & Morris next week, additional interest attaches to the statement, which runs thus: "I long had a desire to explore a high mountain, called by the natives the Morraô, which rises abruptly from the rocky coast near Rio de Janeiro, as I thought it a likely place to find some choice Orchids. I accordingly set out one day with my usual companion, a strong, muscular Brazilian, Profério by name. Providing ourselves with cocoa and dried meat enough for a few days' journey, we started, and after a few days' rough travelling arrived at a little village, where we passed the night. Resuming our journey at daybreak, a small but very deep river laid between us and our proposed track, so there was no alternative but for each of us to strip and swim across, and float our clothes across on large Palm leaves. The bath refreshed us and gave us more zest for our journey, which was through primitive forest abounding with birds, monkeys, and other animals, which, however, we did not molest, as we did not want food; we were, however, under the necessity of killing a few snakes which lay in our path, and did not seem to have any inclination to make way for us. Unhappily, we lost our way, or rather the direction in which we intended to steer, and there being no sign of a habitation of any kind, and night drawing near, we made up our minds to sleep in the woods.

"Rising refreshed at daybreak, we again started after breakfast on our way, cutting our path through the wood till we came to a cabin, the occupiers of which directed us on our road to the Morraô, near which we arrived in the evening, and took up our lodging with fishermen. Next morning we set out with a few men in a canoe and reached the opposite side of the bay, where we landed and collected some plants of *Cattleya guttata*, Leopoldi, Harrisoni, some species of *Catasetum* and *Epidendrum*, *Oncidium*s, and *Bromeliads*, but these did not repay my journey, and I was determined to press on and reach the mountain, which I intended to explore, so we pitched our camp here and intended to stop a few days. At sunrise next day Profério said he could spy plants in bloom on the side of the Morraô, but I could detect nothing with the naked eye; on looking through my telescope, however, sure enough I saw clearly that there were flowering plants, and by the leaves and habit of growth I could see that they consisted of *Lælia elegans*, and by the unusual whiteness of the flowers I knew that they must be of the rare white variety. The plants were seemingly growing in crevices on the face of a steep cliff rising to an immense height directly out of the sea, which dashed furiously against its base. Our first thought was to reach the plants by climbing the cliff, but we were dissuaded by the fishermen, who said that none but flying things could reach

the spot. However, we were determined to get the plants, so I started one of the party back to the village for a man who had been on the top of the mountain some years ago to act as a guide. We took with us provisions for four days, a quantity of rope, and commenced the ascent on the lee side. After much difficult climbing we at length reached the top of the Morraô, the prospect from which I shall never forget, and the mountain itself was clothed with luxuriant vegetation, including *Bromeliads*, whose pitcher-like rosettes of foliage afforded us water to drink.

"We camped for the night on a platform near the top, and next morning commenced to descend towards the cliff on the sea-side where our coveted prize was growing. This descent was the most dangerous I ever had, and never did I experience such strange feelings. Below was the Atlantic, the mighty waves of which dashed with thundering force against the foot of the rocky cliff which we meant to descend, and we fancied the very rocks shivered under us. What made matters worse, too, we had no trees or scrub to lay hold of, only the bare rocks under our feet, and heartily glad were we to reach a little ledge where we could safely rest. In order to further descend we were obliged to make use of our ropes. Descending still, we came to a point beyond which we could not go, for the face of the cliff was literally perpendicular; after a little hesitation, however, Profério volunteered to be let down by ropes, so we tied them round his waist and fastened the other end round the waists of the rest of the party. He began to descend, and was soon swinging in the air in front of the cliff with the sea beneath him. It was quite as much as we could manage to hold him, and soon he was both out of sight and hearing. However, he reached the plants, got a footing where they grew, collected a quantity, gave a signal to be pulled up, when, joyful to behold, he landed safely a bundle of the white *Lælia elegans*. This gave us heart to begin our dangerous and wearisome ascent. We again reached the top and descended the other side with our gathering, which we safely landed in Rio de Janeiro. Two new Orchids, the finest that exist in Brazil, were the fruits of this adventurous undertaking. Besides the *Lælia elegans* there was another *Lælia*, stout in growth, and having very thick bulbs, with large flowers of a tender lilac colour, streaked with crimson and yellow. We have never seen this before and are unacquainted with the species." Mr. Jens Sand also tells us that the beautiful and rare *Cattleya labiata* grows on trees of enormous size, which it is impossible to climb owing to their being inhabited by snakes, which are attracted to them by the water held in the vasiform tufts of leaves of the *Bromeliads* with which they are clothed. The only way to get the plants is to fell the trees, when it is a singular sight to see the snakes decamp in all directions.

Monstrous *Odontoglossum crispum*

—A spike of this Orchid has been sent to us by Mr. Gordon, gardener at The Knoll, Shipley, on which every flower is deformed. The columns are the abnormal parts, each being very much swollen and distorted, and having in the place of stamens petaloid expansions on the top. It shows plainly that even in Orchids the stamens may become transformed into petals, and probably in course of time we may have double-flowered varieties, which, however, will not, we think, be an improvement on the single kinds, judging by that now before us. Other organs in the flowers seem to be perfectly normal, and the variety is a fine one, the blooms being large and prettily marked.

***Cattleya Mossiæ*.**—Some splendid varieties of this Orchid sent to us by Sir William Marriott include some of the richest forms of it we have ever seen; one in particular is remarkable for size, being $7\frac{1}{2}$ inches across and possessing a large shallow labellum of a glowing orange-yellow and exquisitely frilled. It is impossible to intelligibly describe the differences in the forms of these lovely Orchids, which need to be seen to

be properly appreciated. The bright yellow and deliciously scented *C. citrina* also comes to us from Down House, the twin-flowered spikes now sent having been cut from the same plant as the spike which was figured in *THE GARDEN* last year—the best variety we have yet seen. Flowers of *C. guttata* are likewise sent, representing an uncommonly fine variety, with a deeply-spotted and richly-coloured labellum.

Dendrobium Lowi.—Of this very handsome new Orchid Mr. Denny sends from Down House, Blandford, a spike containing five flowers with beautiful buff-yellow sepals and petals and a lip having a conspicuous bristly crest of a reddish buff colour. It is indeed a beautiful and showy Orchid, and well worth, as Mr. Denny remarks, being better known than it is. It is distinct in colour from that of any of the host of *Dendrobes* now in cultivation.

Epidendrum vitellinum majus.—A remarkable example of good culture as regards this Orchid is sent to us by Mr. Denny from Sir William Marriott's garden, the Down House, Blandford. The spike sent is just a foot long, and carries eighteen expanded flowers and four buds. It represents a fine variety both as regards size of flower and richness of colour. From the same collection also comes the lovely white *Epidendrum bicornutum* with five flowers on one spike, also an evidence of skilful culture; and a spike of a remarkably fine variety of *Odontoglossum gloriosum* having larger flowers than usual and more heavily and deeply spotted.

Orchids in flower at Hoole Hall, Chester.—There are at present in flower here *Oncidium Marshallianum* with fifty-eight flowers, *Odontoglossum Alexandræ*—several grand varieties with flowers 4 inches across, *Odontoglossum niveum majus*, *O. Pescatorei*, *O. nebulosum*, and a grand plant of *O. Edwardi*. *O. maculatum*, *O. Roezli*, and *Roezli album* are also in bloom, as are likewise *Ada aurantiaca* with eight spikes, *Cymbidium eburneum*, *Leptotes bicolor*, *Dendrobium Jenkinsoni*, *D. Wardianum*, and *Devonianum*, *Cattleya Mossiæ*, *C. intermedia*, and several others, also *Lycaste Skinneri* and *L. Harrisoniæ*.—JAMES FINALON, *Royal Botanic Gardens, Manchester*.

The Brentham Park Orchids.—We learn that Mr. Robert Smith, of Brentham Park, Stirling, intends to give up the culture of Orchids on account of ill-health, and that his celebrated collection will be sold by auction at Stevens' rooms, King Street, Covent Garden, on May 30 and 31 and June 1. The catalogue numbers nearly 800 lots, many of which include several plants. The collection comprises some of the rarest and choicest of species and varieties, and, judging by what we have seen, it must be in excellent condition. As examples of the varieties to be sold we might mention very fine specimens of *Lælia anceps Dawsoni*, *rosea* and *alba*, *Oncidium Ornithorhynchum album*, *Lælia Jonghiana*, *L. Wolstenholmie*, *L. elegans Hesperia*, *Cattleya Skinneri alba*, *Masdevallia Dayana radiosa*, *Cypripedium Druryi*, *Odontoglossum polyanthum*, *O. nevadense*, *Vanda Parishii Marriottiana*, *Cattleya bogotensis alba*, *C. Trianæ Brenthamensis*, *C. Trianæ alba*, *C. labiata*, *Cypripedium caudatum roseum*, *Oncidium splendidum* and *Aerides virens Dayanum*, *Odontoglossum navium majus*. There are also some exceptionally fine specimens of the Chatsworth variety of *Vanda suavis*, *Dendrobium Schröderi*, *Cypripedium Stonei*, *Celogyne cristata Lemoniana*, *Angraecum sesquipedale*, *Cattleya crispa superba*, *C. Skinneri oculata*, *Odontoglossum Londesboroughianum*, *O. cristatum*, and *O. citrosimum roseum*.

Pear Amedee Thirriot.—This, of which a coloured plate is given in the *Bulletin d'Arboriculture*, appears to be but little grown, but is said by M. Burvenich to take rank with such kinds as *Conseiller à la Cour*, *Soldat Laboureur*, and *Bonne Louise d'Avranches*. It is of vigorous growth and very productive, doing well on the Quince or free stock. Its season commences in November.—J. C. B.

PLANTS IN FLOWER.

ERINUS ALPINUS and the varieties *hispanica alba* and *purpurea*, all pretty and distinct, have been brought to us by Mr. Gumbleton; likewise pretty variegated *Forget-me-not* called *Myosotis picturata* different from *elegantissima*, the other variegated sort, and a double cream-coloured *Daisy* from Algiers; a variety of *Chrysanthemum coronarium*.

AGERATUM PERLE BLEU.—A fine new variety has been brought to us by Mr. Gumbleton, who received it from M. Bruant, Poitiers. It is remarkable for its brightness and the dense character of its flower heads. There is nothing, however, to indicate its habit of growth, an important matter in the case of *Ageratums*.

ALLIUM OSTROWSKIANUM.—This new species, in the way of *acuminatum* and *Macnabianum*, has dense umbels of reddish purple flowers. Mr. Gumbleton brings blooms of it with the major form of *Anthericum Liliago*, also called *algeriense*, and flowers of two species of *Arctotis aureola* and *arborescens*, both with large showy blossoms, which make them desirable greenhouse plants.

CEANOTHUS VELUTINUS is very distinct from the rest of the species belonging to this genus which we have in gardens, and moreover a very pretty shrub. It has roundish shining leaves of thick texture, and bears feathery clusters of white blossoms on the extremities of the branches. Some beautiful sprays of it have been brought to us by Mr. Gumbleton from his garden at Belgrove, Queenstown.

HARDY PLANTS in flower in Mr. Ware's nurseries Tottenham, include, besides many others, *Iritenax* (true), *I. missouriensis*, *I. lutescens*, *I. Chamæiris*, *Trillium discolor*, *Cypripedium pubescens*, *Anemone palmata alba*, *Panocratum illyricum*, *Ixiolirion tataricum*. The new *Iris Leichtlini*, a hybrid between *I. susiana* and *iberica*, has also flowered during the week at this nursery. It is a singular flower and strikingly handsome.

RHODODENDRON KEYSI is so unlike an ordinary *Rhododendron*, that few would suspect it to be one. Its flowers more resemble those of some species of *Aloe* both in form, colour, and in the peculiar dense clusters in which they are borne. They are tubular, about an inch long, orange-red in colour, and, being produced abundantly, are very showy. Mr. Gumbleton brings us a twig or two of it covered with blossom. He also brings a double Ghent *Azalea*, named *Bouquet de Flore*, a pretty pink variety.

PAULOWNIA IMPERIALIS.—A fine flower-branch of this noble tree, carrying numerous large tubular flowers of a rich deep purple, is sent us from the Channel Islands, by Mr. W. Lee, of the Vineyard Nursery, Hammersmith, who says that the tree from which he cut the specimen was 20 feet high and 30 feet across, and bore some thousands of blossoms, forming one of the finest objects he ever saw. Would that we could get this tree to flower with us in England as it does in the genial climate of Guernsey.

MYOSOTIDIUM NOBILE.—The Chatham Island *Forget-me-not* may now be seen in flower in the York Nurseries, some twenty years having elapsed since other specimens of it flowered there. Two spikes, neither of them strong, *i.e.*, compared with those to be seen in its native haunts, give some idea of the appearance of this remarkable plant. The root leaves are very coarse, almost Cabbage-like, deeply ribbed, and of a shining green. Each single flower is about half an inch across, set on a short pedicel, thereby giving the spike a compact appearance. The colour is very rich blue in the centre, margined with a pale band of whitish blue, the flower being in other respects like that of a *Forget-me-not*, except that the corolla is not so thin as that of most of the family. This plant will not be of much use in England, because it is not quite sufficiently hardy for outdoors, and it is difficult to cultivate without the growth getting too coarse, to the detriment of the flower-spikes. One plant had a spike which bore crimson-centred

flowers, but this, though unusual, is attributed to the very drawn condition of the spike, as when withering the centre of so gorgeous a blue at first changes to a pinkish crimson, and when first discovered this plant created quite a sensation on account of its curious combination of flower and leaf.

THE FIRE BUSH (*Embothrium coccineum*) seems to thrive uncommonly well with Mr. Gumbleton, near Queenstown, for again he brings us some fine flowering twigs of it which at once reminds one of a scarlet Honeysuckle. It is a Proteaceous shrub from South America, introduced long ago, but still an uncommon plant in gardens, doubtless on account of its not being perfectly hardy in England and a difficult plant to flower under glass. It is also very difficult to propagate. It was figured in *THE GARDEN* in the latter part of 1876.

A NOBLE DAFFODIL (*Narcissus bicolor maximus*—Leeds).—Of all the *N. bicolor* varieties of the Daffodil this is certainly one of the finest and best. It is dwarf and vigorous in habit. The perianth segments being of greater substance than in *N. Empress* or *N. Horsfieldi*, and the tube being shortened, and the crown or trunk proportionately lengthened, give quite a distinct appearance to the flower. It flowers with *N. bicolor*, and so comes in after *N. Empress* and *N. Horsfieldi* are well high past. As seen growing together by the hundred in good rich sandy soil it is most effective. All lovers of Daffodils should make a note of this variety as one of the very finest of all bicolor Daffodils.—F. W. B.

IMPATIENS SULTANI.—Of this new Zanzibar Balsam the finest specimen that has yet been seen in this country was shown by Messrs. Jackson, of Kingston, at the South Kensington Show this week. It was certainly a marvellous production, being over a yard through, of symmetrical rounded outline, and profusely covered with brilliant magenta blossoms rivaling in brightness those of *Masdevallia Harryana*. Such a specimen as this showed well to what perfection a plant may be brought by such a skilful cultivator as Mr. Puttick, who is so well known for his skill in specimen plant growing. The plant, he assured us, was only eight months old. The exhibitors were deservedly awarded a silver Banksian medal for this plant.

FINE LILY OF THE VALLEY.—Messrs. Hawkins & Bennett's Lily of the Valley is, if anything, larger and finer than ever this season. The flowering stems are 14 inches long, and the foliage attains about the same height from the root, and in many cases 4 inches across. They are grown in beds in the open, those cut in May and April being protected by boards and lights as the weather may require; usually they are covered at night. A quantity is grown in the open to come in at their natural season. The variety grown does not run much at the root, but forms strong plants and bulbs that require little or no thinning. They grow in a rich loamy soil and in an open situation. They like a good bit of manure when planted out at first, and a dressing of short manure on the surface every year. They are grown in Messrs. Hawkins & Bennett's grounds at Twickenham.

SPIRÆA REGELIANA.—This is a species we had not seen before the other day, when Mr. Stevens, of Byfleet, brought a fine flowering branch. It seems to be an ally of *S. hypericifolia*, but the leaves are more woolly and larger. The flowers are white, and produced in the same corymbose manner all along the young shoots, so as to make a beautiful white wreath. Other specimens of attractive hardy shrubs from Grasmere are *Prunus pumila*, a very twiggy dwarf-growing Plum, with every shoot covered with clusters of small white flowers; the double white Cherry (*Cerasus Avium*), also very pretty; *Cytisus purpureus*, an extremely elegant dwarf shrub; and *Buddleia globosa*, branches of which carry numerous globose heads of golden yellow flowers. Some uncommonly fine sprays of *Azalea mollis* likewise accompany these, which plainly shows how well this beautiful shrub thrives with Mr. Stevens in the open air.

FLOWER GARDEN.

CORN MARIGOLD AND OX-EYE DAISY.

ALLOW me to inform "A. D." that, so far from seed of the Corn Marigold not being offered for sale, it has for some time been advertised at 2s. 6d. per packet—a tolerably good price, one would say, for a plant which in many parts of this country is one of the farmer's greatest foes. This bright yellow-flowered weed has so much real merit, that it is well worthy of attention, but it is scarcely fair to call it "the new golden Marguerite," a title which is calculated to deceive such as are not acquainted with its botanical name. "Why, you don't mean to say that is the 'Yellowby,'" said a friend of mine who is more noted for his love of flowers than his knowledge of botanical nomenclature; "our Pea fields were smothered with it last year." Truly the corn lands were last summer quite a mass of brilliant colour with "Yellowby," as it is here called; and, strange to say, for the first

little else is; I have even noticed gay patches of it in December—the flowers not so large nor so bright perhaps as earlier, but still fresh and cheerful looking. By the way, have any of your readers tried it as a winter bloomer? it is good for spring, and I know of no yellow flower which can compare with it at that time of year. The flowers come extra large and bright in the genial climate of a warm house.

Byfleet.

J. C.

THE VIRGINIAN LUNGWORT.
(MERTENSIA VIRGINICA.)

ONE would scarcely believe that such an old and beautiful hardy flower as this is but little known in ordinary gardens, but such is the case, and even in good gardens it is rarely to be met with. Its beauty is unquestionable. It bears large clusters of bell-shaped blossoms varying from a reddish mauve to a delicate porcelain-blue, and the bluish glaucous hue of the broad foliage

Flower spray of *Mertensia virginica* (flowers blue).

time it found admirers. Although in previous years Corn Marigolds have abounded to an unlimited extent, no one thought of plucking a bloom from that "coarse yellow weed;" now all is changed, and many a blade of Corn was trodden under foot last summer in gathering the lovely golden blossoms. Probably few flowers have better illustrated the fickleness of fashion than this. Another native flower which I never remember to have seen gathered until last summer is its near relation, the Ox-eye Daisy, the fair white blooms of which are much superior to the Paris Daisies; it is, indeed, one of the finest single white flowers we have. The great pity is that it does not bloom throughout the season. Those who have meadow land which is fed down and wherein the Ox-eye Daisy grows not should establish it. Cattle do not touch it and the extra amount of food at the disposal of the plants imparts additional vigour to them, with a corresponding effect on the purity and size of the flowers. One of the prettiest of sights is a meadow where this plant grows plentifully; the stary blooms dance in the summer breeze, and their purity is well shown off by the green Grass. Returning to the Corn Marigold, we find it in bloom when

blends beautifully with the tints of the flowers. It grows, as a rule, from 1 foot to 2 feet high, but varies considerably in stature according to its vigour. The chief reason, no doubt, why this Lungwort is an uncommon border flower is on account of its culture—a precarious matter; in many gardens one never sees it making the slightest progress, while in others it grows rankly. The finest plants we have seen of it were grown in moist, sandy peat, in somewhat sheltered beds, conditions that evidently suited its requirements. It is a plant that everybody should at least try to cultivate, for it is very beautiful in the early days of May, quite unlike any other hardy plant that blooms at that season of the year. Other desirable species of *Mertensia* are *M. sibirica*, *paniculata*, *oblongifolia*, the two latter natives of the Rocky Mountains and perfectly hardy. *M. paniculata* is a particularly desirable plant—considered indeed when well grown to be the finest of the genus. It has erect much-branched stems $1\frac{1}{2}$ feet to 2 feet high, bearing an abundance of bright Bluebell shaped blossoms for several weeks in succession during early spring. Our drawing of the Virginian Lung-

wort was made from specimens brought to us a week or two since by Mr. J. Stevens, who grows it admirably in his garden at Grasmere, Byfleet.

ALPINE AND HERBACEOUS PLANTS AT MANCHESTER.

By far the most interesting item at the exhibition at Old Trafford last week was an admirable collection of hardy and alpine plants sent from Newry by Messrs. Rodger, McClelland and Co. Several large baskets were filled with Irish Anemones in all their glory, and such as had never before been seen in these parts. It will not be the fault of our local amateurs if they do not grow the same next year, as the order book of the firm would testify, but I very much doubt if it be possible in our climate. These Irish Anemones are grand, solid-looking flowers, 3 inches or 4 inches across, singles and doubles, of every shade of red and purple, and of the most brilliant hues. In Ireland they can be raised from seed and flowered the year following, and it appears to be possible to accomplish this here by using movable frames, which would protect the buds during the winter months to be removed in spring. Mr. Smith, Messrs. Rodger, McClelland, & Co.'s manager, explained that Anemones could be grown by planting the tubers, but that they never thus attained the beauty of freshly-grown seedlings, and that even these should never be transplanted, but the seed should be properly spaced out, and the plants grown on without a check. This Irish collection was rich in many ways, and was besides this a lesson to our home exhibitors, both professional and amateur, as the plants were shown naturally, not having been forced artificially, and they had a brilliancy and freshness beyond any other exhibits of the sort. *Viola pedata* was shown in all its forms, and some interesting hybrids from seed were amongst the groups of it. Several varieties of miniature Daisies were also very noticeable, and large masses of the Newry varieties of yellow bunch Primroses were greatly admired. Amongst choice alpine plants were *Mitella prostrata*; *Dodecatheon integrifolia* var. *splendens*, with rich red flowers; *Euphorbia epithymoides*, the most showy I have yet seen; *Dianthus glacialis*, *Romanzoffia sitchensis*, *Tradescantia pilosa*, a pretty dwarf form, and a grand example of the Bayonet plant, *Acephylla squarrosa*. There were a hundred in all, and a more choice and interesting lot could scarcely have been selected. I fancy we shall have the pleasure of seeing Mr. Smith again, and some of our other florists would find it worth while to make a show of this sort. Not only would it result in full order books and new clients, but the growing taste for hardy plants would be fostered, and if well grown plants are shown the amateur would have an example which he could emulate.

The contrast was great indeed between the Newry plants and those shown in competition at the other end of the tent. Last year your columns contained communications from several valued contributors—Mr. Harvey, Rev. H. H. D'Ombrian, Mr. Dean, and others—on the subject of the award at the Manchester show, when the prizes had fallen to huge plants flowered by artificial heat, to the exclusion of honestly grown hardy plants and alpine plants of a similar class to those from Newry; this year it was the same. The following was published in the *Manchester Guardian*: "As to the grounds of judgment, what is to be taken as the chief point of merit at a show like this? Certainly not botanical rarity, but the effect produced by the plants as an integral part of the exhibition." One of the successful exhibitors of last year immediately published in a floral paper his method of forcing *Spiraea Ulmaria*, and here again we had it shown 4 feet high, and as unlike its beauteous self as possible. Every exhibitor took his cue from the dictum just quoted, and we thus had staged collections of greenhouse-grown hardy and alpine plants, effective enough as a display, and thus forming an integral part of a popular show, but a melancholy sight to the true florist, and a sorry object for a Royal Botanic Garden to give its patronage to and to reward by its

prizes. Even the choicest alpine did not escape this tropical preparation. *Anemone sulphurea* was shown with a white flower and thin lanky stalk, about half its true size, and without its lovely primrose-yellow. *Phyteuma comosum* was shown with a tiny truss as big as a shilling, mounted aloft on a stalk 4 inches above its yellow-green leaves, instead of with a sturdy Holly-like foliage, and a stout full rosette of deep purple flowers nestled down close amongst them. If this is to be the future manner of exhibiting alpine, the Royal Botanic Society will certainly not foster a healthy love of Nature in our midst. It would have been easy to have taken a far more showy and better lot from any good collection of alpine, flowered naturally and in proper character, and this ought to be a criterion in judging as well as rarity and beauty of bloom.

Brockhurst, Didsbury. WM. BROCKBANK.

CULTIVATION OF THE PANSY.

I WAS pleased to see in THE GARDEN an article on Pansy culture by Mr. Geo. Henderson, of Southwell. He seems to have studied the Pansy (which is also a great favourite in this district) for a long time, and I do not think he has left much room for criticism, although I grow my Pansies in a different way. For a good many years I manured my ground very heavily and had large blooms, but I was always pestered with wireworm and other grubs. Last year, therefore, by way of experiment, I tried my ground without manuring it previous to planting out my Pansies, and used liquid guano ($\frac{1}{4}$ lb. guano to every 2 gallons of water) instead. With this I watered my ground, but not the foliage, once a week for three weeks previous to the day of show, and when the show day came round I had very fine blooms and at the same time healthy plants, free from any sort of grub. This year (also by way of experiment) I have planted my Pansies (about 500 plants) in rotten turf and light loam mixed, and will continue my previous plan of using liquid guano. The following sorts I consider well worth attention, viz.: Fancy varieties—Mrs. Jamieson, Mrs. Barrie, Mrs. Goodwin, Alex. McMillan, Catherine Agnes, Robert Congleton, William Dickson, William Cuthbertson, General Scarlet, Earl Beaconsfield, Miss Bliss, and Mrs. Weightman. Show varieties—David Malcolm, Alexander Watt, Robert Black, dark self; Lizzie H. Bowie, primrose self; Mrs. Dobbie, Mrs. Galloway, white self; Lizzie Bullock, David Dalglish, Mrs. Downie, yellow grounds; Mrs. J. G. Paul, Miss Meikle and Miss Jessie Foote, white grounds. JAMES BOWIE.

Wilderhaugh, Galashiels.

WALLFLOWERS.

THE writer on Wallflowers (p. 426) is mistaken when he says they are grown in nurseries. They are grown in market gardens, and specially in orchards, where, under the overhanging trees, they bloom so early and so well. The writer, too, is at fault in saying that the Wallflower is so hardy. I have often seen very large breadths seriously injured when growing in exposed places. The Wallflower is commonly regarded as a hardy biennial, but now and then, as with Stocks, a sharp winter plays sad havoc with it. Then there is rather too much mixing up of the true indigenous Wallflower (*Cheiranthus Cheiri*), a very inferior plant indeed at the best, with the fine blood-red market variety, the latter being a long way ahead of the former in richness, robustness, and beauty, even though it be less hardy. Only the most persistent selections through generations could have made the garden Wallflower what it is. Then I must take exception to the singular statement that the Wallflower is often the sweetest and finest in cottage gardens. How could it be finer than it is in our market gardens? and how possibly can it be sweeter? Not in one cottage garden in a thousand are to be seen such fine plants, such big heads of bloom, and such superb self colours as may be seen in numbers of market gardens in West Middlesex any spring. It is amusing, too, to read that the Wallflower, "which blooms in the open," is

more highly prized than are the most gorgeous productions of the hothouse, when a dozen huge bunches are sold for a shilling, and as much has to be paid for a single *Gardenia*. Wallflower blooms are popular because they are cheap and abundant. Sell a handful of *Roses* or *Gardenias* or any other hothouse flowers at one penny per bunch, and Wallflowers would soon be relegated to the gutter. To say that is to seem very unsentimental, but it is the truth none the less. Let me add that the gardener's art is not at all employed in striving to produce unpopular hues. We are trying to keep the blood red, the most popular of all hues, as red as possible, and the golden as pure yellow as possible, and reject variegated flowers, because they are in the Wallflower at least unacceptable. A. D.

Golden leaved *Heracleum*.—I send a leaf of a golden *Heracleum* which I found by the roadside three years ago. It is from its large foliage and bright colour one of the most conspicuous of border plants here, and comes true from seed.—J. M., *Charmouth, Dorset*. [Apparently a form of the common Cow Parsnip (*Heracleum sphondylium*), with foliage of greenish yellow, similar to that of the golden-leaved *Valerian*. It is doubtless an effective plant at this season in a border.]

Hollyhock fungus.—Are the enclosed leaves infected with the Hollyhock disease? and if so, what would you recommend me to do with the plants? They are in pots as they arrived from the nursery a month ago, and have been in a cold frame with the lights open night and day ever since.—T. E. F. [The leaves are very badly attacked by Hollyhock fungus (*Puccinia malvacearum*). When the disease has reached this stage it is like confluent smallpox in the human subject, and cure is almost out of the question. It is unusual to receive infected plants from nurseries. As a rule the greatest care is taken by nurserymen to avoid sending out either cuttings or seeds from tainted Hollyhock plants. Your plants may have contracted the disease from the common Mallow, upon which weed the *Puccinia* is extremely common this year.—W. G. S.]

Christmas Roses.—In the pages of THE GARDEN there have been of late many notices of the varieties of this valuable winter flowering plant, and a good deal of discussion regarding the relative merits of the different kinds in cultivation, all very instructive and interesting, but, like most discussions of this sort, if no one offers a test to the disputants year after year we may have the same claimants in the field and the same disputations. Supposing a practical turn is given to the articles in question by the formation of collections in different parts of the country, so that we may be able to judge whether St. Brigid's Christmas Rose, Miss Hope's *angustifolius*, and Mr. Brockbank's *angustifolius* are the same, or if different, their relative value for in or outdoor decoration, and to cut for bouquets and flower vases—an important point, and of most interest to the great mass of readers, while to the few who are collectors the results would be valuable information. On Whit Monday I devoted part of the day in arranging two beds of the different varieties of *Helleborus niger* (Christmas Roses), commencing with *H. niger* from various sources, home and abroad, collected and cultivated plants, selecting from the collected plants the tallest and the most dwarf, those with the broadest and others with the narrowest leaves, and following these *H. niger* major, then Mr. Brockbank's *H. niger angustifolius*, Miss Hope's *H. niger angustifolius*, and the Aberdeen *H. niger intermedius*, leaving space for three specimens of St. Brigid's Christmas Rose and *H. niger variegatus*, which I hope soon to see filled up; following these is *H. niger maximus* (altifolius), and the last row of the second bed is occupied by *H. niger minor*. Should any readers of THE GARDEN have varieties of *H. niger* of special interest, I shall gladly form a third bed from such, and those who desire to make a study of the various Christmas Roses will have free access at all times to this collection. Now

that I have the various sorts on one bed I can venture to say at present Mr. Brockbank's plant appears very different to Miss Hope's, which is a plant of nobler growth, and the foliage of a more pleasant shade of green than Mr. Brockbank's.—PETER BARR, 12, *King Street, Covent Garden*.

Circular Pansies.—On reading the note in THE GARDEN (p. 422) on circular Pansies, I went at once to a bed of a very fine showy belted variety named Bronze Beauty much grown in this district as a decorative or border kind, and gathered a good average flower. This gently pressed on paper formed a circle $2\frac{1}{4}$ inches one way and $2\frac{3}{8}$ inches the other. This will suffice to show that there are Pansies nearly round, if not absolutely so, and these not even florists' selected kinds. The huge flowers which come from Vilmorin's and other Continental strains are generally deeper than broad, and therefore not so much valued for their form as for their size and rich colouring. Their drawback is found in their great size, causing them to "flop," to use a common, but expressive word; hence they are not so striking and effective in a bed or border as many smaller flowered varieties. Moreover, they are not nearly so floriferous, and they have nearly all a sprawling habit. For cutting for nosegays they are, however, very beautiful; but at what a sacrifice if to employ them a big piece of the wood is to be cut with them. It is right to say that these huge Continental varieties are almost the only ones of the big fancy section that will come freely from seed and do well as border plants. The beautiful fancy kinds shown by Messrs. Hooper, Downie, Cocker, and others somehow seem never to get into commerce by means of seed, at least no one appears to be able to get them here in the south. Inferior kinds of course seed most freely and these come freely, but if we want really hardy free growing, large showy flowers we have to fall back upon the rich coloured, and yet cheap, Continental strains.—A. D.

Planting Pampas Grass.—Although to all appearance a very hardy plant, and likely to bear a good deal of rough treatment, the Pampas Grass is much more easily injured than its appearance would indicate. In the first place, it is not a hardy plant in the strict sense of the word. A severe frost may not perhaps injure it, but cold north and east winds do. Even in Somerset the plants suffer severely from this cause, and the older the plants, the more they suffer. Even now the north sides of all our old plants are sadly disfigured. This evidently shows that a somewhat sheltered spot is the best for them. Intending planters, therefore, should bear this in mind, and select for them positions where they can have shelter from the quarter indicated. Then as to treatment. There is nothing particular in that after they get established, but it is pretty well known that it is not so easy to get them established, as they do not like being removed. The best time to transplant them is undoubtedly the month of May; they will then quickly form new roots, and take kindly to the soil if prepared for them as it should be, by being broken up fine and pressed firmly about the roots. In all cases of doubt as regards the natural soil of the locality it is best to prepare stations for them by removing any of an unkindly character, and replacing it with new material of a better description. The soil that suits them best is a deep friable loam resting on gravel. It is quite true that they grow fairly well in other descriptions of soil, but there is a great difference in the appearance of plants grown under exactly the conditions that suit them and those not so grown. The same remarks apply to the after management. Few think of supplying the Pampas Grass when in active growth with liberal supplies of manure water, yet few subjects are more benefited by it; and as to results, there is no comparison between those that have been so treated and those that have not.—J. C. C.

Bluebell and Hailbell.—What is the difference between these two plants?—ROSA. [A wide one. The first is the popular name for *Scilla nutans*, a plant of the Lily family; the second is applied to several kinds of *Campanula*, usually those with slender stems and small, thimble-like flowers as in *C. rotundifolia*.

ROSE GARDEN.

NEW YELLOW ROSE WANTED.

OUR Rose Canon, when describing in his own felicitous way the unparalleled merits of *Maréchal Niel*, is compelled to add, by way of caution: "This Rose is somewhat capricious, and liable to sudden and mysterious decay, so that it is best to have a young plant coming on, and to keep up a sure succession." "S. D." says (p. 427) many complain that the *Maréchal* goes off at the union between stock and scion. That is bad enough, but not all that can be said against the *Maréchal*. It not only goes off at the point of union of scion with stock, but anywhere and everywhere else likewise at times. Climbing *Devoniensis* stock is "S. D.'s" remedy for this. By all means let it have a trial. I believe that *Maréchal Niel* has been strangled through constricting stocks. On the climbing *Devoniensis*, or on any other free-growing Rose it would have more freedom; but we have tried most stocks, from *Gloire de Dijon*, one of the best, to the white and yellow *Banksian*, and found a tendency to gout in plants worked on all these stocks, therefore it must be concluded that this troublesome disease is neither cultural nor climatal, but constitutional. Canon Hole seems to have come to the same conclusion. Hence he says nothing about budding, grafting, or growing this grand yellow Rose out of this weakness. But accepting the disease as more or less inevitable, he urges growers to keep up a succession of plants. Were this gangrene or gout in the stems a matter of stocks only or wholly, it follows that plants on their own roots would escape. But this is so far from being the case, that not a few of these have suffered most. In worked plants the disease is mostly confined to the point of union between the scion and the stock. But in those on their own roots a huge gangrenous wart not seldom attacks and destroys the main stems or all the leading branches either abreast or in detail one after the other. The *Maréchal* being somewhat tender, were it only attacked in the open air, the disease might with good reason be supposed to originate in sudden chills or checks of the sap. Being a vigorous grower, any sudden arrestment of growth might readily so powerfully affect the tissues of constricted parts of the branch, as to produce extravasation of the sap. Then by a process somewhat analogous to that of gumming, the disorganisation, swelling, and total destruction of the wood follows. But this disease is equally or more destructive under glass as in the open air, so that the arrestment theory is untenable. As a rule

THE LONGEVITY of *Maréchal Niel* is greater in the open air than under glass. If I am not mistaken, the first, or one of the first, to arrive in England is still alive in the open air. And until the cruel havoc made by the past two winters among our standard *Maréchals* we had some venerable veterans in the open with wide-spreading heads that never failed to yield us two crops a year. These were by far our oldest plants, and they were killed not by gout in their stems, but by frost. Once this gouty swelling appears on a main stem or branch, the plant or part affected is doomed. The whole of the life goes out of it. Not only does the bark swell and dry up, but the wood also, the whole becoming light, dry, and lifeless as a sponge. And yet the first step of the disease seems to arise from constriction rather than enlargement. There is in the first stage a hard dryness about the affected part as if it had been burnt with a hot iron. From this stage swelling, disorganisation of tissue, and death speedily follow. Many of the

ABNORMAL ABORTIONS bear what seems to be traces of insect agency, but most likely this succeeds the disease, and may not be in any degree responsible for its cause. These gouty swellings are generally most numerous and destructive on the dormant part of the main branches or main stems. When breaks have been forced near to these the gout has seemed to be less destructive. This dormancy of base is one of the penalties we must often pay for the laying-in of

those monster shoots with which the *Maréchal Niel* has done so much to familiarise us. One has hardly the heart to recommend their being shortened, seeing that they may break in showers of golden beauty along the greater part of their length. But when practicable, it is wise to bend them round, as one does Vines, to force the shoots to break regularly back to their bases. Otherwise the tremendous flood of sap needed for the sustentation of such masses of foliage and solid weight of flower-buds may prove too bulky for its channel, and result in distension and final disorganisation and disease. This guess at the truth is merely advanced for what it is worth, and one thing is certain, that whether this theory regarding the disease proves right or wrong, no *Maréchal Niel* Rose can be the worse for the possession of one or more free-growing shoots near its root-stock or the base of its main shoots.

WEAK FLOWER STEMS.—One thing more is wanted to make the *Maréchal* perfect—a stronger neck or stem. It is singular, and so far unfortunate, that such a giant in vigour, and such a prodigal in the use of golden petals to build up such masses of fragrance and beauty, should deal out stem material so sparingly that few of these magnificent Roses can hold their heads erect. Wiring is all very well; but how much better for the plant to do its own work, and set its cups of gold on footstalks, say, as stout and strong as those of *Gloire de Dijon*. *Maréchal Niel* has now about attained his majority, and the time seems opportune for suggesting a match that may result in originating a golden Rose that shall neither hide his head in his bosom, nor die of gout in the very beginning or heyday of his glory. Surely it would be well worthy of the National Rose Society to offer a prize of fifty guineas for a golden Rose equal or superior to *Maréchal Niel*, but without its defects.

D. T. FISH.

GLOIRE DE DIJON ROSE.

To the many other good qualities belonging to this grand old Rose may be added the facts that it seems disease-proof, and probably the longest lived Rose which we possess. In these two admirable qualities it presents a striking contrast to some of the finer Tea and other Roses. Unless smitten or killed by frost, which it rarely is, there is seldom anything amiss with the *Gloire de Dijon*. The older it grows the more freely it flowers, and that is about the only effect of old age on the *Gloire*. But in the best sense Roses of the style and habit of *Gloire de Dijon* never get old. They are constantly undergoing a process of regeneration. The strong shoots that they seem ever ready to throw forth on the gentlest hint from the cultivator virtually form young plants on the broad foundations of the old stools. And these recuperative processes are constantly going on, especially when *Gloire de Dijon* is grown as it ought to be, on its own roots. But our purpose now is merely to emphasise the value of the advice given by "S. D." to plant this Rose on different aspects for a succession of bloom. I have already strongly recommended it as probably the best of all Roses for the clothing of walls, and the best of the *Gloire* is that it will grow with almost equal freedom on walls of any and every aspect. On south walls early stray blossoms may be gathered early in May, and sometimes earlier in favourable seasons. It is rather singular, however, that the *Maréchal Niel*, though much more tender, is also earlier in the open air on a south wall. East and west aspects seem equally welcome to *Gloire de Dijon*. Some of the finest formed and sweetest scented blooms of this fine Rose ever gathered by the writer were grown on an east wall with several points of north in it. And this leads us to state that, useful as this Rose proves grown on the three most favourable points of the compass, it is yet more useful grown

ON A NORTH WALL. In the cool shade of such a position the Roses lay on a colour and a fulness of fragrance which they seldom or never acquire when exposed to the midday sun's broad glare. The effect of shadow on the colour and fragrance of

Roses is one of those points that has not yet received the attention it deserves. *Gloire de Dijon* Roses gathered from off southern and northern aspects could hardly be believed by the uninitiated to be the self-same variety. Nor does the sun merely dispel colour—it dissipates sweetness. The difference in fragrance in favour of Roses grown on a north wall is far more pronounced than in regard to colour, great though the latter is. Few Roses can equal the *Gloire* in its rich diversity of colour. Almost every possible shade of yellow, fawn, orange, salmon, buff, saffron are illustrated in the varied colouring of this splendid Rose. On the whole it is much darker as well as richer coloured from a north wall. And neither is the improvement effected by coolness and shade confined to a heightening of its colour and an increase of its fragrance. The form of the Rose is also greatly improved. Unless in bud, few rosarians go into raptures over the form of the *Gloire*. It is a style of Rose in which form is partly dispensed with on account of its many other sterling qualities. But grown on a north wall, the blooms of the *Gloire de Dijon* seem to find time to reconstruct or remodel their material and greatly improve their form, so that altogether we get something like a new *Gloire* among our Roses by simply growing the old one on a north wall. For the comfort of those who have no wall to spare, even for *Gloire de Dijon*, it may be added that most of the above advantages may be scored by anyone who will simply grow this fine old Rose, either as a dwarf or a standard, in different sites. The *Gloire* is not simply the best wall Rose, but also as a standard or for forming beds or masses as a dwarf. Treated thus it will produce a profusion of bloom, most of them of the very highest quality. One of the most successful methods of treating the *Gloire de Dijon* as

A BEDDING ROSE is to plant strong plants from 1 yard to 5 feet or 6 feet asunder. Encourage a vigorous growth in from six to a dozen shoots; permit these to ramble wild and free the first season. In the following autumn or spring cut away the whole of the old wood that may have bloomed the previous year, and peg down these strong shoots regularly all over the surface of the bed. These will flower with the utmost profusion, while the strain put on their base by being sharply bent down will cause other strong shoots to break forth. These should be treated as before, and the flowering shoots again removed. In this way the plants are really renewed every year, while the constant demand for and furnishing of successive flowering wood keeps the roots in full swing and the plants in vigorous health.—D. T. FISH.

— This grand Tea Rose for all round use has no equal, more especially as regards the many ways in which it can be grown and profusely flowered. We have here growing up the rafters in the greenhouse four plants of it, and from these I have already cut ninety dozen lovely blooms. I began cutting on March 3, and I have cut on an average ten and twelve dozen weekly. It may be mentioned that the same plants have nearly completed a second growth, which will furnish a second supply of bloom. The season being unusually late, outdoor Roses will be some time before they open. The plants alluded to are growing in a border on each side of the house, round which a stage runs. The house is kept constantly filled with plants, so that the Roses have the advantage of a greenhouse temperature. On the same roof *Lapagerias*, *Plumbago*, and other climbers are growing and flowering equally well. I would advise anyone possessing a greenhouse to plant *Gloire de Dijon*, it being sure to flower where other tender kinds would fail.—J. CLARKE, *Brynkinatt*.

GUANO FOR ROSES.—The best way to apply guano is to sow it on the surface, choosing a moist time, and rake it in. Good Peruvian guano is an excellent manure for Roses, and if the soil is at all impoverished, a good dressing of it should be given, and the rains will carry its nutritious properties down, so that the roots can utilise them by the time the plants come into growth.—J. C.

LEAVES FROM THE SOUTHERN ALPS.

All places that the eye of Heaven visits
Are to the wise man ports and happy havens.

Richard II.

My leaves are gathered this time very far from the Southern Alps, in fact, 1200 miles from Mount Cook, but then they are holiday leaves, and have a licence to be erratic. I am going to concern myself in this bunch with the botany of Tasmania, where in the course of a ten days' stay I came upon some interesting novelty almost at every step. This delightful island is so full of charming flowering plants, that in the course of my short visit—although I was seldom idle—I was able only to gain a good general idea of its vegetable wealth, and to obtain specimens of the more noteworthy plants. As for carefully investigating the ground over which I passed, to that I make no pretension, for my stay was too short, and I covered far too much ground to have carefully botanised it. My experience in and around Hobart were such as to leave with me a strong desire at some future time to have three weeks' botanising in the neighbourhood, when it would be possible to investigate a considerable area of very varied conditions with some degree of thoroughness. On December 12, then, we are at

Hobart, as this little city is now called, the "town" being dropped, and, sick of the sea, for it had been far from kind, we rise in the grey morning about four o'clock and take a walk abroad, full of that curiosity which every one feels, but more particularly he whose hobby is his garden, on first sighting a new country. Tasmania on this particular morning does not reveal much of herself. The hills that rise all round Hobart are clad in a very sober livery of grey cloud. From the warm earth rises the fragrance of a shower that has fallen in the night, and every flower and weed has a newly washed appearance, very refreshing to the eye. It is very pleasant to walk along the streets of this quaint little town on a morning of this kind. Two features of Hobart more particularly strike a visitor at first sight; one is its cleanliness, and in this respect it may be contrasted with its rival in commercial importance—Launceston. Its streets have a washed, almost scoured appearance, and the houses and public buildings have the same clean look. This is probably in a great measure owing to the very general use of a fresh sandstone for building purposes. The other noteworthy feature—and to one who has lived long in a colonial town a very charming feature—is its decidedly Old World air. Hobart was evidently not born yesterday. It has not the temporary run-up and raw look of most colonial towns. The houses have a solid, thick-walled appearance, as if they had been built to exclude summer's heat and winter's flaw, and were meant to outlive generations of tenants. Each house—of course I speak in general terms—has its garden in character with its architecture—old Box-edged walks, sometimes a growth of Ivy (they have not the abominable grub that destroys ours), a verandah draped with a glow of creepers, *Dolichos*, *Solanum jasminoides*, *Fuchsias* (bushes of a small red kind, something like *globosa*), *Honeysuckle* of a beautiful amber yellow, *Lonicera confusa*, I believe, *Abutilons* 6 feet high, occasionally a tall *Cactus*, a *Passion-flower*, or a *Tacsonia*. Some gardens are surrounded by high stone walls, which are actually old and crumbling—a rare sight in this quarter of the world—and from the cope sprout growths of red and white *Valerian*, *Mignonette*, rock *Roses*, and such things. In praise of the

TOWN GARDENS—with one honourable exception, the Royal Society's Gardens, of which more anon—not much can be said. They have, as a coach companion remarked to me, a "broad-cast" sort of look, just as if the owner had a recipe for some patent mixture. Candytuft, red and white, half an ounce; *Clarkias*, half an ounce; *Lupines*, 1 ounce; *Pansies* (of a very weedy kind), 6 ounces. Mix well together, season all with yellow *Feverfew ad lib.*, and sow broad-cast before a shower of rain. This gives a sort of glare of colour, but the effect on close inspection is not satisfactory. Neither are the gardens well kept; indeed, this style of gardening does not consort with trimness. Scarlet

fever is, I should imagine, always prevalent in Hobart. Look in any direction you please, the eye is sure to rest on masses of bright scarlet *Geraniums*—scarlet, scarlet everywhere till the eye gets sick of it. Indeed, in Hobart you have only to stick in a piece of *Geranium* and you have a mass of scarlet growing and growing in perpetuity. In walking along the quiet streets, however, the eye occasionally lights on a plant that arrests attention. In every second garden the *Solanum jasminoides* clambers about hanging, its festoons wherever it can get a peg to hang them on, and bearing a fine crop of clusters of pure white blossoms. Another *Solanum*, too (*S. orientale*, an African species, I think), seems a great favourite, and it is certainly a very striking plant. It is about 4 feet high, has large leaves with undulating edges covered with a thick tomentum, which gives the whole plant a pretty frosted appearance, and bears small white inconspicuous flowers, which are succeeded by a yellow fruit like a small Orange. One of the prettiest plants I saw grew in a little garden a few yards square in front of a tavern. It was a single white *Holly-hock*, very tall, and set all the way up the stem with large blossoms of a pure colour and good substance. Single *Dahlias* may be very pretty and fashionable, but not many of them could match the beauty of this single *Mallow*. The favourite shrub seemed to be the New Zealand *Laurel* (*Corynocarpus laevigata*), or *Karaka*, as the Maoris call it. It has broad, coriaceous, glabrous leaves of a light green, and is one of the most beautiful of *Evergreens* when well grown. It is very remarkable that, although there are so many beautiful native flowering plants about Hobart, including a large variety of herbaceous plants and hard and soft-wooded shrubs bearing charming blossoms and often succeeded by equally charming berries, yet its gardens are mostly stocked with weedy, third-rate annuals and florists' flowers. If the Hobart gardens were filled with the more beautiful plants that grow within a radius of six miles from the city, their shrubberies, borders, and rockeries might compete in interest with those of the best English gardens. Instead of this, however, native plants are rarely to be seen, their places being taken by blotches of *Geraniums*, or whatever else will give the greatest amount of colour with the smallest expenditure of labour. In Hobart itself the most interesting quarter is, no doubt,

THE DOMAIN, which lies to the east of the town. This is a large extent of ground reserved for public recreation; the surface very undulating and covered with moderately large-sized specimens of *Eucalyptus*, chiefly the *Manna Gum* (*E. viminalis*). This Gum, which is very abundant throughout Tasmania, is not one of the gigantic species, seldom exceeding 60 feet in height. The leaves are narrow and sharp, and the branches somewhat drooping. The whole tree has a somewhat twisted and irregular shape, and the bark, as is the case with so many of the Gums, comes off in flakes. This *Eucalyptus* gets its popular name from the deposited excretion of a hymenopterous insect which sometimes infests it. I observed that the trunks of many of the trees in the Domain were charred about one-third of their height, but could get no information as to how this happened. Probably, however, the dry Grass round their roots occasionally catches fire from a burning match thrown carelessly amongst it, and, spreading, at last kindles the dry and very inflammable strips of bark that hang from the trees. At any rate, the appearance of the trees is not improved by the traces of fire. Amongst the Gums are various other trees, and on the ground, creeping amongst the Grass, a variety of pretty wild flowers.

THE COMMON WATTLE is plentiful through most of the Tasmanian forests. *Acacia dealbata* ("Silver Wattle," as the colonists call it) is a tree of some economic value, the bark, under the name of "Mimosa bark," being a very considerable article of export. It is well known as a foliage plant in English greenhouses, but, of course, from pot specimens only a very imperfect idea can be formed of the appearance of this pretty Wattle when it grows to the dimensions of a forest tree

and covers large tracts of country, loaded with millions of its fluffy primrose blossoms, and filling the air with its rich perfume. By the time I saw it in its native habitat the blooming season was pretty well over, and only an occasional tree—for evidently some individuals are later than others—was still in flower. Sir J. D. Hooker says that the Silver Wattle in deep, dark forests reaches the height of 100 feet; but although I saw large areas filled with it, I remarked no tree of any great size, the most common form in which it appears being as an undergrowth for Gums. Occasional specimens, however, reached respectable dimensions—some 40 feet to 50 feet. Taken singly, the Silver Wattle is a pretty, graceful tree, the trunk rising lithely up, and the branches with their light green *Mimosa* foliage projecting lightly and airily from the main stem. The massed or distant effect is, in my opinion, not so good. The glaucous green and the silvery pubescence of the foliage give a greyish neutral tint to an *Acacia* forest, which on longer acquaintance might come to be agreeable, but which to the unaccustomed eye has an unsatisfactory, mouldy effect. All aspects of Nature must be beautiful to those who have a sufficiently long acquaintance with them, and I have no doubt that with familiarity the eye grows to be delighted with sights which, like an *Acacia* forest, fail at first to impress it. As for such a forest in the full flush of bloom, it must be a ravishing sight; but, unfortunately, as I have said, only an occasional late tree carried bloom when I saw the Tasmanian Wattles. Here and there through the Domain are dotted specimens of a large shrub called

BURSARIA SPINOSA, the general appearance of which in full flower has the effect of a tree of English May. The *Bursaria*, sometimes called the Christmas Tree, from its being in bloom about that time, is exceedingly common throughout the island. In the course of a sail about 40 miles up the Derwent great numbers of this tree may be seen along the banks of the river, and they serve very pleasantly to enliven the generally sombre character of the *Eucalyptus* scenery. The short lateral branches are sometimes changed into strong sharp spines, whence the specific name. On that side of the Domain which runs down to the Derwent a good many specimens may be seen of the quaint

SHE OAK (*Casuarina quadrivalvis*), an extremely interesting representative of an extraordinary family. This species does not grow to any great height, 20 feet being about the maximum growth. Its branchlets droop something after the manner of the cassowary's feathers, whence the generic name of *Casuarina*. The common name of "She Oak" illustrates that curious grouping of popular nomenclature after some significant sound, which has changed the Rose Quatre Saisons into Quarter Sessions Rose, and Gloire de Dijon into Glory de John, and which has translated the unpronounceable *Bellerophon* amongst sailors into the more manageable Billy-ruffian. The *Casuarina* bears no relationship to the *Quercus* family, although she is a distant cousin of the Birch and Alder. The name "She Oak" is said to be the corruption of a North American word "sheack," and colonists have even gone so far as to name another plant (*Casuarina suberosa*) in contra-distinction the He Oak. There is a remarkable resemblance in the whorled and fluted character of the twigs of the She Oak to the habit of growth of the common British Horse-tail.

THE CHERRY TREE OF TASMANIA (*Exocarpus cupressiformis*) is another domain tree, or rather shrub, for it seldom reaches the dignity of a tree. Anything more unlike a Cherry could hardly be found in the tree world, for it has no leaves, but instead has beautifully translucent pale green branchlets, resembling more the finer varieties of Cypress than any other tree. This shrub has the drooping habit of the She Oak. The resemblance to the Cherry comes in in the fruit, which has a swollen scarlet edible peduncle. I was not, however, fortunate enough to see it in fruit, neither, although young plants were plentiful, could I secure a specimen with a good root or

ball of soil. Some pretty native wild flowers grow amongst the Grasses that carpet the Domain. Prettiest amongst them is

THE AUSTRALASIAN HAIRBELL (*Wahlenbergia gracilis*), our representative of *Campanula rotundifolia*, the Bluebell or Hairbell of Scotland. It is a very widely distributed plant, occurring in Australia and New Zealand as well as in Tasmania. But although it is one of our most common plants, I had never been able to admire it much until I saw it in Tasmania, forming patches of blue under the trees just as if flakes of sky had fallen on the earth. The bell is wide and shallow and divided into a variable number of lobes. It differs from the Scottish *Campanula* in having the bell not depending, but upright—the mouth not facing the earth, but the sky. This is one of the most variable of plants in size, habit, and colour. With us in New Zealand it is small and generally of a very pale lavender or pure white. In Tasmania, on the other hand, it is very large—three-quarters of an inch across the mouth, and of a very rich, clear lilac-blue—though I observed that there was a difference of shade in different individuals. Those who are fond of the *Campanula* family would find the *Wahlenbergia*—of the Tasmanian strain—a valuable addition to their collections if they can get it to come at all true, which I fancy it would

forth so fair a fruit. This little fairy flower is the very Ariel of Bindweeds—a wreath wherewith to crown Puck withal. The corolla is about a quarter of an inch broad, and of a lovely flushed pink; the leaves are of two forms, the lower ones being deeply lobed, the upper ones reduced to mere lines. Sometimes the pink sprays fall over the edge of a bank, sometimes lie prostrate, and sometimes they twine round a stalk of Grass or bind two stalks together. The polymorphous character of this Bindweed makes it a puzzle to botanists. It is a great traveller, appearing in Tasmania, Australia, and New Zealand, Africa, Europe, Asia and America under a host of aliases and disguises. I secured good ripe seed of the Hobart form, and will have much interest in seeing what forms will come from it. PAKHA.

GARDEN IN THE HOUSE.

SWEET-SCENTED GERANIUMS.

SOME of these should be grown wherever cut flowers or hand bouquets are in demand, the fragrance of the foliage and its pleasing form rendering it suitable for the choicest of floral combinations. In the case of flowers which are mounted with wire, the individual leaves may be used with

Basket of cut flowers.

do. Those who wish to get a supply of this or any other Tasmanian seeds obtainable in the neighbourhood of Hobart would find their orders attended to by Mr. John Latham, of Liverpool Street, whom I myself found most obliging and attentive as well as reasonable in his charges.

THE CHEERY OXALIS CORNICULATA is another cosmopolitan little fellow, opening its varnished yellow florets whenever it gets the least encouragement from the sun. Like the *Wahlenbergia*, it is also a native of New Zealand and Australia, and is our representative of the charming little *Oxalis* of the British woods, with its delicately veined, pearly white flowers—"Birdie's Biscuits," as we used to call them. The corniculata flower is followed by long, narrow pods of seed, which when ripe are of a most excitable temperament. In collecting the seed the pod must be handled in the most gingerly fashion, or puff! the walls burst and the seeds go helter-skelter in all directions. The Protean little

BLUSHING BINDWEED (*Convolvulus erubescens*) creeps along the ground of the Domain, opening its ruddy little corolla if the day is only bright enough. There is not much use in describing this flower, for it runs through a whole gamut of forms, the extremes of which it is difficult to believe to be forms of the same plant. The Domain form is one which I subsequently found growing in great abundance on the Melbourne racecourse. It seems to me, since I have come to compare it with other specimens, to be a depauperised form of the plant. But never has poverty brought

excellent effect. Supposing the flower to be mounted is a *Camellia*, three good-sized leaves are arranged round it and fixed in place by a turn of the wire. The same may be done with other flowers, such as *Azaleas*, *Primulas*, *Violets*, &c., the smaller blooms being mounted three or more together according to their size. The form of the leaves of scented *Geraniums* better fits them for this purpose than those of any plant I know, as they clasp the flower naturally and seem to fix and hold it in place, and if so arranged that their much divided ends project a little, the formal outline which many choice flowers present is much relieved. When the plants are liberally grown throughout the summer, good strong shoots will be available, which cut entire will be found very serviceable for informal floral arrangements. In a trade establishment where bouquets were largely in demand we used to grow a considerable quantity of sweet-scented *Geraniums* for the sake of their foliage, which was used in the manner above described, only employing Maiden-hair Fern for finishing off round the outside of the bouquet. Bouquets made with these scented *Geranium* leaves have a very neat appearance and are withal most gratefully perfumed. Every year in June we used to fresh pot the stock, which consisted of some hundreds, many of them veterans from which thousands of leaves had been cut; we discarded a portion of the old soil, and gave them a free, tolerably rich compost, rather richer than it is the custom to give *Geraniums* generally, the object in this case not being to induce a floriferous habit, but rather a luxuriant growth with some exuberance of leaf development. Were I again to grow any number of sweet-scented *Geraniums* for the sake of their foliage, I would certainly plant them out, as if carefully lifted they do not appear to suffer, the leaves not damping off as is the case with zonals. The plants above alluded to were wintered in a cool house along with a collection of show *Pelargoniums*; they occupied the back portion of the structure, needing less attention than anything else therein; and if an account of what they brought in during the year could have been kept, it would, I think, have been found that they were among the most profitable plants, either tender or hardy, grown in the establishment. From November to June they might be said to be daily earning money. J. C. B.

ferous habit, but rather a luxuriant growth with some exuberance of leaf development. FILLING FLOWER BASKETS.

THE accompanying illustration of a flower basket which was awarded a gold medal at a recent flower show in Germany may perhaps afford a suggestion to those who have to arrange cut blooms in that way. The basket shows tasteful arrangement in some respects, but it is somewhat too flat, rather overcrowded, and perhaps displays too much variety as regards kinds of flowers. Had more Tea Roses been employed and more elegant foliage, the effect would have been better. This reminds us of a charming flower basket which we saw the other day, and which contained nothing but the yellow *Maréchal Niel* and the blush-pink President Roses associated with their own foliage, and to relieve the flatness a few sprays of the new feathery *Asparagus* (*A. plumosus*), more elegant even than any Fern, and lasts so much longer in perfection. As in most other floral arrangements, nothing is better than simple and light arrangement, using a few kinds of flowers only. If a mixture of many kinds is employed the result is seldom artistic or pleasing. At this season the open-air garden contains, or should contain, ample material, and that of the best description with which to arrange flower baskets and vases. The Daffodils just past have yielded a long and plentiful supply, and the stragglers, the double and single Poet's Narcissi, are still in beauty. The managers of flower shows, particularly in the country, where professional floral decorators seldom make their appearance, should encourage simple arrangements of this kind instead of the mixtures which one often sees arranged apparently without regard to either harmony of form or colour.

NOTES FROM SCARBOROUGH.

I SEND you a few of the naturalised *Scilla campanulata*, which grow in myriads on our cliff, and also a few of what seems to me an intermediate variety between it and the common wild *S. nutans*. If I am not mistaken, this is a large and early form of *S. campanulata*. The typical form with narrower leaves and smaller flower-spikes is hardly open as yet, and this is at the very height of its beauty. It will be interesting to me if you think it a distinct variety, as we knew of it on our cliff for something like 100 years, and it always keeps larger and earlier than what I imagine to be the type. [The intermediate form to which you allude is probably the same as that named *S. cernua*—merely a variety of *S. nutans*.]

Cypripedium pubescens is in great beauty, and seems thriving in its third season; to me it is even more charming than *C. spectabile* and easier to grow, as it does not require so much wet. *Aralia Sieboldi* has proved more impervious to bitter sea blasts this last season than even *Acubas*, and *Olearia Haasti* is the only shrub that can boast that not one leaf is browned; it is of the greatest value in a seaside garden. *Veronica* bushes and *Dracena Veitchi* are making fresh growth, but have suffered much. *Choisya ternata* is now in nice flower in company with *Pittosporum Tobira*, both having escaped injury in a sheltered corner, and are consequently to be recommended.

Eucryphia pinnatifolia again has made fresh leaves without pushing an inch of growth, and I

hear of its being stunted elsewhere. Can anyone tell us of this shrub thriving in the open air? For once, where so many complain, we can say our Roses look better than usual; both Teas and Hybrid Perpetuals are pushing strong growths and making fine foliage—the precursor of fine flowers, let us hope. The wet and cold of the winter have done great damage among bulbs and tender Lilies. Clumps of *Hyacinthus candicans* that had thriven for years outside are all dead. I only see one weak shoot from patches of *Ornithogalum arabicum*. *L. Humboldtii*, *Parryi*, *Szovitzianum*, *tigrinum splendens*, *Washingtonianum*, *candidum*, and *longiflorum* are all very much weakened or killed outright—a most disheartening sight. *L. giganteum* is, however, thoroughly happy, and seems to thrive as readily as a *Funkia*. I wonder why this Lily is not generally called hardy and grown commonly.

E. H. W.

INDOOR GARDEN.

INTERMEDIATE HOUSE.

THE intermediate house (see p. 415) being, as its name implies, for plants that require somewhat less heat than a stove and yet more than a greenhouse, should, as far as heat is concerned, be kept at a temperature midway between the two, say at 55° night temperature during the winter months, allowing it to rise gradually as the season advances, till by midsummer a night temperature of about 70° with a proportionate rise during the day is reached. In the hottest weather no fire will be needed, and even should it turn out chilly, which in our variable climate frequently happens, a good deal may be done by shutting up early, and thereby husbanding the sun heat. Select flowering plants for a house of this description should include *Begonias*, such as *semperflorens* and its deep-coloured variety, *valida*, *manicata*, *pruinosa*, *Moonlight*, *Welltoniensis*, *insignis*, and others; also *Pentas carnea* and *kermesina*, *Plumbago rosea*, *Linum trigynum*, *Sericographis Ghiesbrihtiana*, *Libonia floribunda*, *Poinsettia pulcherrima*, *Eranthemum*, *Bougainvillea glabra*, *Clerodendron fallax*, *Luculia gratissima*, *Lagerstroemia indica*, *Lasiandra macrantha floribunda*, *Pleroma elegans*, *Rogiera gratissima*, and *Magnolia pumila*, which flowers freely in a small state, and when in that condition would fill the house with delicious fragrance. The greenhouse *Rhododendrons* of the Princess Royal type would also in such a temperature continue to grow and flower more or less continuously throughout the year. The following are good and distinct kinds, viz., *Princess Royal*, pink; *Princess Alexandra*, white after a time slightly suffused with blush; *Taylori*, rich pink, white tube and throat; *Duchess of Teck*, buff yellow, shaded with rose; *Duchess of Edinburgh*, bright orange-crimson, and the pure white *Jasminoides*. Such a house would also serve to maintain many greenhouse plants in flower during the winter for which additional heat at that time of the year is necessary. Amongst them should be *Salvias*, *Heliotropes*, *Bouvardias*, tree *Carnations*, *Epiphyllums*, *Hebeclinium inianthum* and *atro-rubens*, and zonal *Pelargoniums*. *Achimenes*, *Gloxinias*, *Gesneras*, and *Tydeas* might likewise be successfully grown, and in summer *Torenia Bailoni* and *Fournieri* continue to flower a long time in succession. *Clerodendron Balfouri*, *Iloya carnososa*, *Manettia bicolor*, *Stigmaphyllon ciliatum*, *Rhynchospermum jasminoides*, and *Thunbergia Harrisii* would be found to be good climbing plants. No better place could be found in which to propagate most greenhouse plants than a house of this description; the few degrees higher temperature would greatly hasten the emission of roots, especially in the case of soft-wooded plants inserted in spring.

H. P.

PREPARING AZALEA MOLLIS FOR FORCING.

FEW will question the adaptability of this *Azalea* for forcing, but it is not always convenient to give it the special treatment which it requires for this purpose. In order to meet the difficulty, it may be useful to say that there are two ways of dealing

with the plant, applicable to both large and small gardens, and with no great difference as regards results. In the case of those who have sufficient house room, no doubt the most satisfactory way is to grow the plants always in pots. This is our own way of dealing with them, and we have no cause to complain of the quantity of flowers which they produce. Our plants are taken to the forcing house early in December, where the temperature is maintained at about 45° by night and 55° by day, and the plants are generally in flower by the middle of January. As soon as they go out of bloom they are turned out of their pots, their roots are examined, and if they require more room they are at once shifted into pots one size larger, the soil which we use being peat and sand only. As soon as shifted they are taken to a cool Peach house, where they are kept just secure from frost, and where they remain until they have completed their growth, which is generally by the end of May. They are then placed in the open air, and at this stage they require rather careful watching. If the flower buds are at all prominent, the plants must be set in a cool shady place, or some of the buds will flower prematurely in September; but if the flower buds are not visible when taken from under glass, they should be set in an open sunny position and allowed to remain there all the summer. In other respects this *Azalea* is very easy to manage, for it is quite hardy. It is not troubled with insects and only wants a reasonable amount of attention as regards watering. For gardens in which there is not much room, or where it is not desired to cultivate them in pots, two sets of plants are required, and a piece of ground containing a suitable soil must be set apart for them. In this case there should be one set of plants forced every year, that is to say, the plants which were in flower at the beginning of the present year will now be planted out, and allowed to remain so until the autumn of 1885. This will give them one season's growth made under natural circumstances, which will, in the ordinary course of things, be in just the right condition to produce plenty of flowers when taken up and forced. Under this treatment they are forced one season and rested the next, and there is no reason why, under careful management, they should not last for many years. If it is desired to keep them from getting too large, they do not object to being pruned, but the pruning must be done in the winter succeeding that in which they were forced. In the case of plants grown in pots, pruning must be dispensed with if the plants are expected to flower every year. If the sacrifice of one year's flowers is of no importance, then moderate pruning may be resorted to; but it must be done in winter, when the plants are at rest.

J. C. C.

HEATED WALLS.

THERE are many good gardeners who believe that, in discarding the old-fashioned flued walls, as has been generally done, they parted with one of the best helps to a good crop of Peaches outdoors that they ever possessed. Cheap glass, permitting the erection of glasshouses instead of walls, very largely accounts for the neglect into which heated walls have fallen, and for our part we should prefer a glass roof to a wall at any time; but glasshouses are more expensive at the outset, and need constant management and looking after to render them useful, and there are many people who can have the walls, but not the glass, who would like to grow Peaches if they could, and with the least trouble and expense. Besides it is an open question yet whether walls that are merely covered by glass, but not heated, are any better than heated walls. Our own opinion is, that any glasshouse for Peaches should have the means of excluding frost and damp in spring and autumn, for reasons that have frequently been given in the *Field*, and need not be repeated here. We are acquainted with numerous examples of large unheated Peach cases, and we are not prepared at present to admit that they are one whit better than the old heated wall. As for glass copings, we are sure they are not so good, for in frosty or cold weather they make scarcely any perceptible difference to the tem-

perature. A few degrees of frost are fatal to Peaches in flower under protectors 2 feet wide or more. They keep off wet, but a 9-inch board does this equally well. We have never yet met with a gardener possessed of experience of heated walls who would admit that they are useless; and there are those who will tell you that in many gardens outdoor Peach culture has become a dead letter since they were discontinued, the crops on these structures having been invariably excellent for many years. Some say that it is the climate that has deteriorated and prevented crops; but it is not so, for fruit can yet be had from warmed walls as it used to be. In some of the coldest districts in Yorkshire Peaches used to be a famous crop on heated walls. These were done away with, and it has been found since to be quite impossible to ripen the wood of the trees. One of the best of our outdoor Peach trees from a cold wall was given away to a cottager, who planted it against his kitchen flue, and during the whole time he was tenant of the house that tree bore good crops which it had never done before.

THE ADVANTAGES of heated walls are easily understood. Whether heated by means of flues or hot-water pipes, the heat is equally diffused throughout the brickwork (in order to have most heat on the south side of the wall, where the trees are, there should be no more than one course of bricks on the south side of the cavity in the wall, and the rest of the bricks should be on the north side), and both day and night the temperature of the air within from 6 inches to 18 inches is several degrees above the general temperature of the atmosphere. Gardeners who have stood in cold weather nailing trees in front of a heated wall know what a difference the heat from it makes to their fingers, but few people comprehend the difference this greater degree of heat makes to the trees. A mean of one degree one way or the other will make a perceptible difference in the time of ripening a crop of fruit or anything else, and two or three degrees may mean either a hopelessly late or an unusually early crop; but in the case of Peach trees on warm walls any novice may observe the effects. Where, on an unheated wall, a Peach tree will perhaps ripen 6 inches of its annual growth before the end of November, it will ripen 12 inches or 15 inches on one that is heated. This difference in the length of the annual shoots is a great matter. The more and better ripened growth we can add to a tree in a season, the sooner it will attain to the desired size, and the sooner and more abundantly will it bear fruit; and this greater growth is in itself also a guarantee of the maturity of the wood, upon which fertility depends more than on anything else almost. With a 9-inch wooden coping at the top of the wall to throw off the wet trees in bloom are almost quite safe from the severest late frosts we are likely to experience. Unlike glass screens, heated walls do not bring the trees forward too early in the year, and that is a more important matter than we are apt to suppose. Ventilate glass screens as freely as we may, and they are seldom ventilated enough. We cannot prevent them becoming too hot frequently during sunny days in February and March, with the result that the trees are forced into flower while there is yet much danger of severe frosts that a glass roof cannot exclude, and the crop is done for, may be, in a single night; this has often happened in unheated houses. On heated walls, on the other hand, the rule used to be not to apply heat till the trees began to grow freely of their own accord, perhaps about April or May, and then the fire heat was applied as a protection when it could be no longer withheld; and this is the secret of getting crops. The worst crops of all kinds of outdoor fruits in this country follow early springs, because these are usually succeeded by destructive frosts at the critical season; and so it is with Peaches on the open wall—a late blossom is more likely to escape, and will at least need less protection. Trees on heated walls should not be trained to wire trellises unless these are strained close enough to the wall to touch it, for shoots nailed close to the wall ripen and bear best, because they receive most heat.

THE CONSTRUCTION of heated walls is a very simple matter. They should be built hollow from top to bottom, and the two sides be only held together by ties. A cavity 9 inches wide inside is not more than sufficient, and the back of the wall may be one brick thick (9 inches), and the front, or south side, half a brick. This is about the thickness of an ordinary solid brick garden wall; hence a hollow wall is really the cheapest, even after allowing for a couple of rows of 3-inch hot-water pipes along the bottom for heating purposes, for flues are not so good as pipes, nor so cheap in the end. The above amount of piping enclosed within a wall is soon and cheaply heated. The cavity becomes as hot as an oven; the heat slowly permeates the bricks, and raises the temperature about the trees by day and sustains it by night, expelling severe frosts simply by its radiation from the wall. The heat should, of course, be most used in spring and autumn—in spring to keep off frosts and raise the temperature of the air near the trees as long as the weather is cold; and in autumn to ripen the wood, which is of quite as much importance as protecting the trees in spring. Plenty of remarkable examples of the effects of warm walls could be furnished. During frosty winters we remember a certain garden where many of the herbs, such as Sage, &c., growing on a border near to the front wall of a hothouse survived the winter, while those plants a few feet further off perished. We saw not long ago in a cold locality near Huddersfield a very large Fig tree covering a mill wall against the engine house, which was always warm. On this tree, I am told, good crops are gathered every year. On cold walls Figs will hardly grow, let alone bear, in the same neighbourhood.—*Field*.

PRITCHARDIA GRANDIS.

THE appearance of a new plant under the name of "the true *Pritchardia grandis*" will most likely lead to some misunderstanding unless some light is thrown on the subject; and as I happen to be acquainted with the history of both the "spurious" and the "true" *Pritchardia grandis*, perhaps you will permit me to endeavour to set the matter right. It will be remembered that some eight or ten years ago Mr. Bull introduced from the South Sea Islands a distinct and beautiful Palm which he called *P. grandis*. Of this a figure was given in the *Gardeners' Chronicle* in 1874, and in the note accompanying it the writer expresses some doubt as to the correctness of the name, and states that "Mr. Bull's name must be accepted provisionally only." The *début* of this plant was made at Ghent in 1876, and proved so successful, as to enable Mr. Bull to sell one of his plants to Mr. J. Wills for a good many guineas. I believe that of the three plants Mr. Bull succeeded in establishing in his nursery one was fatally injured at the Ghent exhibition, one died, and the other Mr. Wills secured. This plant is now in the Kew collection, and is about 12 feet high. In 1880 some young plants of this so-called *Pritchardia* were introduced into this country, and of course they were immediately snapped up by those who were acquainted with its beauty, and perhaps also its money value. Meanwhile the director of the Hanover Botanic Gardens, a great authority on palmology, had pronounced the name *Pritchardia* incorrect, and referred the plant to its proper place, calling it *Licuala grandis*. Concerning this matter Mr. Wendland writes to me as follows: "The first moment I saw Mr. Bull's plant I perceived it had nothing to do with *Pritchardia*, but that it was a true *Licuala*." "A Rose by any other name would smell as sweet," and the beauty of this Palm was in no way detracted from by the alteration of its generic name.

This year another very beautiful Palm was exhibited at the Ghent show, and was dubbed "*Pritchardia grandis* (true) of Wendland." Now I had seen this plant and I knew that it was no more a *Pritchardia* than that introduced by Mr. Bull. I therefore wrote Mr. Wendland, who replies to the effect that he has not seen this new plant, and therefore could not be answerable for

its name. The *Pritchardias* are so well characterised as to make it impossible for anyone knowing them to refer this new Palm to that genus. If it is anything, it is certainly a *Licuala*, and so far as I can make out an entirely new species. It is one of the most beautiful Palms known, and if I might venture to suggest a name I should suggest that of *Licuala Veitchii*. Through the kindness of Messrs. Veitch I have been enabled to compare their plant with *L. grandis* and with the *Licualas* both in cultivation and in the herbarium at Kew. Messrs. Veitch's plant differs from *L. grandis* in having spines along the margins of the petiole from the base to the blade, whereas in the latter species they are found only on the lower portion of the petiole. The blade differs in being less distinctly lobed and in the sinus being much less deep than in *L. grandis*. The two plants are near each other and are so noble in habit, as to be worthy of a place in the choicest collections.

Pritchardias are distinguished by their large fan-shaped leaves, which are covered with a white mealiness when young, and the blade is always of a soft papery texture. The leaf-stalks are stout, spineless, and always covered with a white meal. At Kew there are the following species in cultivation: *P. pacifica*, *P. Martii*, *P. aurea*, *P. Gaudichaudi*. W. WATSON.

Kew.

FRUIT GARDEN.

EXTENSION VINE BORDERS.

IF I read "J. C. C.'s" communication on this subject (p. 375) aright, his sole objection to restricted Vine borders is the short time during which Vines flourish in such borders—an objection valid enough if it were not possible to treat such borders at but little cost, so that they would at least maintain Vines in as vigorous a condition and for as long a period as the alternative plan which he proposes, and I for one think very much longer. Suppose, for instance, that Vines are allowed to ramble at will through one of the principal quarters of the kitchen garden, what about the roots to which he so frequently alludes as coming to the surface in search of warmth, &c.? Why, at every digging, not to name trenching, a great bulk of them would be cut away—that is, if they ever came near the surface at all, which is doubtful. That they would probably descend into the subsoil out of the way of both spade and warmth is certain—as undesirable a condition for them to be in as to be suffering from restricted root space. No, no, Mr. J. C. C.; you must give us a better plan than this, and some other material than "flagstone" with which to cover the borders for "generating heat" before we can give up our plan of root restriction—at all events within reasonable limits. This extension plan for Vine roots might be successful if the space at command were a fertile pasture resting on a sandy or gravelly subsoil, but such positions do not often fall to the lot of Grape growers, and it is therefore useless to dwell on the results that might be expected, or to advocate this kind of border. With respect to Vines being short-lived in restricted borders, I think, to some extent, the notion is a mistaken one. I have a house under my charge that my employer believes to have been planted nearly sixty years ago, and the border is but 26 feet wide and surrounded with a brick wall built with cement and the bottom concreted, yet these Vines every year bear a larger aggregate crop of fruit than any of our young Vines. The only point in which they do not equal the young Vines is size of bunch, a point of but little importance if we accept as gospel all that the producers of small bunches tell us of their performances, statements which, when I read them, I usually supplement by saying that the Grapes must be sour as well as small in bunch. I am willing to admit that the well-doing of these Vines for so long a period in such a restricted space is an exceptional case, but a case that would not be so rare if Vines generally were always so well cared for as these have been in the matter of annual top dressing with new soil, and at intervals of

three or four years digging out a trench next the boundary wall, lifting up the bottom roots, and cleanly cutting back all other roots found in digging out the trench, operations which as it were give the Vines a new lease of life. New rootlets are quickly formed at the end of every cleanly cut old root, and immediately push into the fresh soil. This manner of treating restricted borders, namely, giving them annual rich top dressings, and occasionally adding new soil at the extremities, has been more successful than any other plan I have tried, next to new border making and entirely new planting, which as a matter of course is an expensive affair, but if it were not, I would say pull up and replant about every six years; you will then get larger bunches and plenty of them, which will be superbly finished with a minimum of labour and anxiety as regards bad setting, scalding, and shanking.

W. W. H.

Large Cherry trees.—Can any of your readers inform me if they have ever met with larger Cherry trees than those the dimensions of which are as follows: 1, 11 feet 3 inches in girth; 2, 10 feet 3 inches; 3, 9 feet 5 inches; 4, 9 feet? I have many more here ranging from 8 feet to 9 feet. The circumference I have taken at 4 feet 6 inches from the ground. The trees are in full bearing, although the fruit is small—a black description of Cherry.—R. TUNSTALL MOORE, *Steadiat, Balbriggan, in Field*.

Small-flowered Peaches for forcing.—May I assure your correspondent that what I wrote on this subject was what has really been my experience? I know what excellent forcing kinds *Noblesse* and *Dr. Hogg* are, and I have them both in the house to which reference was made, and they have never quite failed me; still, they have partially done so, but the small-flowered ones never. I therefore contend that I had a right to assume and to record the fact that with the self-same treatment the small-flowered varieties were best for early forcing. Remember, I said early forcing for the simple reason that in later houses we are never troubled to get an abundant set of any variety. May I ask that Mr. Westcott would favour us by telling us what are the important points in which the large-flowered *Dr. Hogg Peach* and *Lord Napier Nectarine* are superior to, say, *Crimson Galande*, *Bellegarde*, *Magdala*, and *Royal George*?—W. W. H.

ENGLISH PLANT NAMES.

IS it not a little unreasonable to expect every amateur gardener to learn Latin names for all the plants grown in his garden? Professional gardeners, nurserymen, and botanists must perforce use them as a part of their legitimate stock-in-trade, but are they wise in throwing them as difficulties in the way of the general public? It is acknowledged that there are difficulties in the way of the general use or acceptance even of English names, but that surely is no good argument against their due usage in a right and suitable manner. Steam and telegraphy once presented difficulties and perplexities seemingly insurmountable—now electricity as a lighting agent does the same; but because the thing may be difficult to use or perplexing to organise, it does not follow that the principle is wrong. Latin names are perplexing enough if one tries to remember all those that have been applied to such a common plant as the *St. Bruno's Lily*; but in practice one Latin name only becomes general and so it will be eventually with English names. "Calf's Snout," for example, as applied to the common *Snapdragon*, is not pretty, and even in Parkinson's time had begun to give way to the better and prettier English name which the plant now bears. What we now want is a good compilation of all the best known, if not of all the English names now in use in books or garden literature. One or two partial attempts at this have been made already, but a comprehensive work on the subject is yet a desideratum, and one which I have reasons for hoping will be supplied at no

very distant date. The wonder is that English names are now so popular and general as they are, seeing that they are for the most part traditional and legendary rather than universally fixed in books on botany and gardening. The simple fact of their having lived on in the poetry of the people and in the language without having had any especial care or culture proves pretty conclusively that they are of some classic and permanent use. Popular names are like popular books—one must produce them, and trust to the public at large for a verdict. My own opinion is that if true and good they live; and if inexpressive or bad they die—the common fate of all that is bad and useless all the world over. "T. B." (p. 403) touches the subject as if uncertain of his own opinion, and the result is we are not quite sure whether he is for or against the use of popular names. It would be better if one's opponents were at least worthy of good steel, since opinions with an uncertain ring are next to useless in serious questions of this kind. With what "Rho" advances (p. 404) everyone must to a great extent agree. He says, "Satin Flower" may be preferable to "Rush-leaved Lily," but I must ask both Mr. Tymons and "Rho" to remember that in Vol. XI. of THE GARDEN (p. 110) we have *Brodiaea coccinea* figured and described as the "Crimson Satin Flower," which name was at the time held to be preferable to that of "Vegetable Fire Cracker," the popular name applied to it when it was introduced to our gardens. Even Latin names do not always retain their priority, and so no doubt English names will be subjected now and then to the same alterations. To this no objection can be justly urged, provided always that the alteration or substitution is for the better. To retain a name radically false and bad simply because it is the oldest is not conducive to that progress in garden matters which some of us are so anxious to see.

Mr. Elwes argues in a narrow groove when he objects to Professor Owen's English names of garden birds. He writes (p. 404), "There is a capital instance of the confusion which results from incorrect nomenclature in Professor Owen's notes on birds in THE GARDEN, and if it were not for the Latin names (of which, however, many are obsolete or incorrect) I should not always have known what birds were alluded to." Mr. Elwes' own popular names, as applied to the species of *Lilium*, come in, as it seems to me, for a large share of his own argument as applied to Professor Owen. In his "Monograph of the Genus *Lilium*" we find English names applied to all the species, but so poor are these—mostly translations of the Latin—that were it not for the Latin names, as he puts it, the whole question of Lily nomenclature would be in confusion. As there is a large coloured diagram of each species in Mr. Elwes' book, we know pretty well what he means, and I always feel inclined to pin my faith to figures, and so accept his own English names, although why he rudely threw away his principles and admitted them into his book is a mystery to me. As an instance of bad popular nomenclature, take white Lily for *L. candidum*. We have several white Lilies, and the older and more classical name of *Madonna Lily* might here well have been retained if Mr. Elwes did not feel equal to the finding of a better and more expressive one. Again, take *L. longiflorum* (the long-flowered Lily), another inexpressive and so far untruthful name, seeing that Lilies with much longer flowers are now in cultivation. If euphony is to be a factor in the giving of popular or English names, may we be defended against such ugly nomenclature as Maximowicz's Lily. After that somebody will want us to adopt the Mexican popular name for *Cattleya citrina*, which, however glibly it may fall from the tongue of a Mexican, looks fairly unpronounceable in English—"Corticoatzcoatecochitl." We must honour Mr. Elwes by printing a list of the English names he has thought well to employ in his work on the genus *Lilium*. The Latin names are added to prevent confusion. It is truly a curious effort on the part of an author who avowedly is against the use of popular names. Apart from its serving a noble duty here as a warning, a list of all the Lilies

will be useful for readers of THE GARDEN to refer to as occasion may require:—

Lilium philippinense, the Philippine Lily.
L. Hansonii, Hanson's Lily.
L. pomponium, the Pompon Lily.
L. Parkmannii, Parkman's Lily.
L. auratum var. *Wittei*, Witte's Lily.
L. pyrenaicum, the Pyrenean Lily.
L. testaceum, the Nankeen Lily.
L. Davidi, David's Lily.
L. polyphyllum, the Many-leaved Lily.
L. giganteum, no English name.
L. philadelphicum, the Philadelphia Lily.
L. davuricum, the Siberian Lily.
L. croceum, the Orange Lily.
L. carniolicum, the Carniolian Lily.
L. candidum, the White Lily.
L. tenuifolium, the Narrow-leaved Lily.
L. chalcedonicum, the scarlet Martagon Lily.
L. Browni, Brown's Lily.
L. monadelphum, the Caucasian Lily.
L. japonicum, Kramer's Lily.
L. Martagon, the Martagon Lily.
L. superbum, the Swamp Lily.
L. Leichtlini, Leichtlin's Lily.
L. callosum, Siebold's Lily.
L. parvum, the small-flowered Rocky Mountain Lily.
L. neilgherrense, the Neilgherry Lily.
L. pardalinum, the Californian Lily.
L. tigrinum, the Tiger Lily.
L. carolinianum, the Southern Swamp Lily.
L. elegans, Thunberg's Lily.
L. cordifolium, the Heart-leaved Lily.
L. washingtonianum, the Washington Lily.
L. Wallichianum, Wallich's Lily.
L. Maximowiczii, Maximowicz's Lily.
L. avenaceum, Fischer's Lily.
L. concolor, Salisbury's Lily.
L. oxypetalum, Royle's Lily.
L. maritimum, the Coast Lily.
L. longidorum, the Long-flowered Lily.
L. bulbiferum, the Bulbiferous Lily.
L. Humboldtii, Humboldt's Lily.
L. columbianum, the Oregon Lily.
L. speciosum, the Lance-leaved Lily.
L. canadense, the Canada Lily.
L. auratum, the Golden-rayed Lily.

It is by no means right to assume that this question of English names is threshed out. Those who feel it incumbent on them to oppose the movement "on principle" should lose no time in doing so firmly and decidedly, for the good seed is growing apace. Practically all the commerce of the world is carried on easily and smoothly without Latin. One does not ask for fruit of *Vitis vinifera* and *Vitis corinthiaca*, or for the crystallised sap of *Saccharum officinale* when we want currants, raisins, or sugar, neither do we quarrel with the baker in Latin when we want that product of *Triticum* which some of us call "household bread." The vegetable products of the whole world are bought and sold under English or Anglicised popular names; but if we want to buy a double red Daisy for the garden forsooth, it is, say the critics, to be called *Bellis perennis flore-plena rubra*!

It may be the business of gardeners (however humble) to learn Latin names, but this parrot talking in a dead language may be too much encouraged. I have met with people who insisted on employing Latin plant names who could not tell me the Latin for the silkworm or for the seal, or for "bread" and "water" or for a thousand and one of the stern realities of life around them. Latterly I notice a tendency among gardeners to know lots of pet Latin names for "good things," but who have not even a "nodding acquaintanceship" with the plant itself, and will even fairly fall over it without recognising it when it is before them. This may seem an extreme example, but it is true. When we look over Shakespeare and the works of all our great poets we find no Latin, but we understand and know the flowers they name. Even old Parkinson 250 years ago wrote whole pages on his favourite blossoms without a word of Latin. So does the florist, who is a very apostle of popular nomenclature at heart; and perhaps rightly so, but so soon as a pretty and expressive name is given to a plant popularly nameless and comparatively unknown in most gardens, so soon do we

hear the old parrot cry of "Wolf! wolf!" when there is no wolf, and the result is that false alarms become unheeded.

My argument is that all plants must at first have a good expressive Latin name given to them (a good figure should always accompany this first christening), and in addition to that a good English name also for the use of those who think a little of Latin names for their plants as they do of Latin names for their houses and furniture, their domestic animals, or the garments which they wear.

F. W. B.

GARDEN FLORA.

PLATE CCLXXXIX.

VARIETIES OF *PERNETTYA MUCRONATA*.*

AT one of the meetings held at South Kensington last autumn a group of seedling *Pernettyas* in fruit, exhibited by Mr. Davis, Ogle's Grove Nursery, Hillsborough, Co. Down, Ireland, attracted a good deal of attention, not only on account of the profusion in which the berries were borne, but also on account of the wide range of colour which existed amongst them. The typical *Pernettya mucronata* forms a low-growing evergreen shrub, with small, deep green, sharp-pointed leaves, hard and leathery in texture, and in spring thickly studded towards the tips of the branches with small, white Lily of the Valley-like flowers, which in autumn are succeeded by crowds of berries each about the size of a large Pea and crimson in colour. It is a native of the extreme southern point of South America, viz., around Terra del Fuego and the Straits of Magellan, and is quite hardy in this country. It was introduced, according to Loudon, in 1828. The collection from Ogle's Grove represented the results of many years' patient labour, some thirty years having elapsed since the first seedlings were raised there. They were the offspring of the hardiest and most free-fruited variety of *Pernettya mucronata* then in cultivation, viz., *angustifolia*, and amongst the seedlings were several that varied considerably from the type both in foliage and colour of the berries. From seeds of the most promising of these other seedlings were raised—work which has been carried on till a collection has now been produced, which is matchless as regards variety, hardness, and free fruiting.

THE VARIETIES represented on the accompanying plate show the great difference there is amongst them in the way of colour, ranging as they do from deep blackish maroon to almost white, but besides those here figured there are others of intermediate, but distinct tints well worth attention. When exhibited certificates were awarded to six of them, viz., *carnea nana*, *alba*, *sanguinea*, *nigra major*, *purpurea*, and *macrocarpa*. These names refer to the fruit, foliage, or habit, and in no case to the flowers, but when in bloom these *Pernettyas* are so pretty as to suggest to hybridisers the desirability of taking that feature also into consideration in their future operations. Differences in the size of the flowers in their colour, and also in their time of opening are points that deserve attention. These Ogle's Grove *Pernettyas* promise to become a very popular class of shrubs; their neat foliage and habit render them always bright and cheerful, and in spring their beauty is much enhanced by the multitudes of little white bells which they bear and which in autumn are succeeded, as has just been stated, by clusters of berries. If untouched, the latter remain on the bushes through the winter, but birds

* Drawn from specimens sent by Mr. L. F. Davis, Ogle's Grove Nursery, Hillsborough, Co. Down, in October last.

1871. 1872. 1873. 1874. 1875. 1876. 1877. 1878. 1879. 1880.

are apt to make short work of them if the weather is severe. I have seen large masses of the common *P. mucronata* stripped of their fruit by birds in a very short time, and doubtless the varieties here represented are equally attractive to them.

CULTURE AND POSITION.—In common with most Ericaceous plants, the *Pernettyas* are essentially peat-loving subjects, yet, like many other plants, we often find them thriving in soil not at all peaty; indeed, a kind of marly loam seems in many cases to meet their requirements, and even if the soil is scarcely suitable, the addition of a little peat and decayed vegetable matter to it will in most cases remedy that drawback. A hot, dry, sandy position is the most trying for them, as although they delight in an exposed and sunny spot, it is only on condition that their roots are always kept moderately moist, as the young fibres perish when too dry. In the form of a large mass or clump these *Pernettyas* have a very handsome appearance; when dotted here and there their beauty is comparatively lost. How many of their allies, too, are there that, when grown in masses or groups, instead of each plant standing out singly, would form really handsome clumps, while in most gardens they are quite the reverse. The reason for this is evident, as, though the different kinds of Ericaceous plants delight in sunshine, they dislike heated soil around their roots. When in masses the ground is always shaded and moist. Among the plants to which allusion has just been made may be mentioned the different kinds of *Heaths*, *Cassandra calyculata*, some of the *Andromedas*, *Gaultheria Shallon*, many *Vacciniums*, *Zenobia speciosa*, the *Clethrads*, and the same may be said of *Rhododendrons* and *Kalmias*. Another use to which *Pernettya mucronata* has been put in many places during recent years is furnishing flower beds during winter, and no doubt when more plentiful the Ogle's Grove varieties will also be sought after for that purpose; but, though very pretty and cheerful under such conditions, the continual shifting necessary prevents them from displaying their attractiveness to the fullest extent, while if a part of the garden were set aside for *Pernettyas* and their allies (the American garden, for instance), it would always prove interesting, for where shall we find a brighter flower and a more persistent winter bloomer than the little *Erica carnea*? or what among bedding plants can surpass the gorgeousness of some of the *Rhododendrons*? In

SOWING SEEDS OF *Pernettyas* take care that they are never allowed to become dry. A good place for them is a cold frame with about 6 inches of sandy peat therein, in which the seeds should be sown. The berries should be rubbed up in and mixed with some dry sand before sowing.

ALPHA.

The process of curing Grapes (*i.e.*, of converting them into raisins).—Long strips of coarse cloth or matting are spread upon the smooth ground—the poor use the uncovered earth or rock—and the clusters, cut from the Vines, are dipped in very strong lye, and laid upon the cloth to dry in the hot sun, which requires several days. The raisins are then carefully separated from the dry stems, and packed in bags ready for use. In some parts of the country they are dried in clusters. This fruit forms an important part of the diet of the people, and is regularly laid up with other provisions of the household. A man often makes a meal simply of bread and raisins. Among the Hebrews it seems not to have been the custom to strip the raisins from the stems, but to dry them in the bunch, as is now done in the province of Malaga, in Spain. Orientals always eat the Grape whole, as experience has taught them that the skins and seeds contain an astringent quality which renders this fruit most wholesome,—*Bible Lands*.

SEASONABLE WORK.

FLORAL DECORATIONS.

LILY OF THE VALLEY can now be had in abundance. Large handfuls of it may often be seen bunched up together and placed in a vase with but a small proportion of foliage. A better way in which to arrange these lovely flowers is to first place a goodly amount of their own foliage in any vase sufficiently deep to avoid shortening the spikes, which should then be inserted one at a time till sufficient have been arranged to allow each individual spike to show itself off to the best advantage, and somewhat after the manner in which they are seen growing. We have found a few growths of *Myosotis dissitiflora* to harmonise exceedingly well with them, being likewise very durable where the receptacle holds a fair amount of water. For a somewhat bold arrangement, and one adapted for a sideboard or entrance hall, select the graceful arching spikes of *Solomon's Seal*; a vase with a black or dark ground would suit well for these. Sprays of *Laburnum* are very pretty used along with *Wistaria sinensis*. The former also looks well associated with the foliage of the purple *Beech*. Trusses of the yellow *Ghent Azaleas* are now very useful; we employ them in many ways. In specimen glasses with a few pieces of *Forget-me-not* mixed with them they are most attractive. A leaf or two from the young growths of *Berberis Aquifolium* with its fine bronzy colour is a valuable addition. *Violas* and *Pansies* can be turned to good use by way of variety in the arrangements. These look well in a flat dish with Moss to keep them fresh; a few pieces of either ground Ivy or of any other creeper may be interspersed amongst them. *Rhodanthe*, pink and white, can now be had, and they make excellent subjects for cornucopias of centre-pieces for the dinner-table when used in conjunction with any of the ornamental Grasses either wild or cultivated. For the bases of centre-pieces just now the bold showy flowers of the *Clematis*, both white, pale blue, and lavender, and also deeper shades, are all excellent adjuncts where variety in arrangement is indispensable. These flowers may also be recommended for their durability. Tea-scented *Roses* are at all times appreciated for their lively tints; when arranged by themselves, I think they display their beauty to the best advantage. When carelessly grouped together in a trumpet vase (using their own foliage) nothing looks better. Pieces of *Clerodendron Balfourii* in flower have a pretty effect when used in conjunction with a few spikes of *Begonia nitida odorata*. A stray blossom of *Datura Knightii* (the double form) we recently cut and placed in the entrance hall, where its perfume was not found to be too powerful, as might have been the case if placed in a close room.

FLOWER GARDEN.

GIANT FENNEL.—For planting by the side of water and in other moist positions there are few hardy herbaceous perennials equal to the Giant Fennels; certainly none excel them in elegance of foliage and habit of growth. The varieties *communis* and *gigantea* are those most generally cultivated, and indeed they are the only kinds worthy of a place in ornamental gardening. They are of the easiest culture; the seeds should be sown in February in heat, and as soon as germination has taken place the young plants should be grown on in an intermediate house and planted out in permanent positions in May. The soil should be a stiff, deep loam, and if not naturally moist, abundance of water should be given during the summer time. The first season the plants will not grow more than 3 feet or 4 feet in height, but in the course of a year or two they will reach 8 feet or even 10 feet. We have a large bed of the variety *gigantea* and *Bocconia cordata*, another hardy herbaceous perennial, planted alternately, and the effect is all that can be desired, the tall flower-spikes of the *Bocconia* being shown off to the best advantage by the giant Fern-like foliage of the *Ferula*.

ROSES, CLIMBERS AND ANNUALS.—*Roses* being very forward, owing to the mild winter, the March winds terribly injured the tender foliage and shoots, an injury which it is to be feared will render the plants an easy prey to the attacks of fly and mildew. It will, therefore, be advisable to keep a strict look-out for the appearance of both of these pests in order that remedial measures may be at once taken. To destroy fly, there is nothing better than clear water, applied with force through a syringe or garden engine; for mildew use soap-suds, and whilst the plants are still wet dust them over with sulphur. Should leaf-rolling maggots be troublesome, the only sure cure is to pick them off and burn the leaves in which they are ensconced. Keep all that have been recently planted thickly mulched, and in dry weather water freely. Brier stocks should be kept clear of all shoots except those that are to be budded, and root suckers should be destroyed as soon as perceived. The foregoing remarks are equally applicable to *Roses* on walls and verandahs, with this addition, that where there are projecting eaves that prevent rain reaching or washing the plants, artificial watering will be more frequently requisite. Clematises and other climbers now need weekly attention as to direction of growth and training; sticks or strings should be placed to such annual climbers as *Canary Creepers*, *Nasturtiums*, *Convolvulus*, *Scarlet Runners*, and *Sweet Peas* before there is any danger of the growth getting matted together. Seeds of all these may still be sown, and also of the quickest growing dwarf annuals, such as *Virginian Stocks*, *Candytufts*, *Clarkias*, *Limnanthes*, and *Nemophilas*, and finish planting out *Asters*, *Stocks*, *Phlox Drummondii*, *Zinnias*, *Indian Pinks*, *French and African Marigolds*, ornamental Grasses, and *Everlastings*.

GENERAL WORK.—At the present time there is no lack of this, and good generalship as to the direction of work is necessary if the varied operations are to be done at the right time; with this object, let each day's work be arranged the preceding evening, and be done in the day, even though the usual hours of work be exceeded, for only by such persistency can we hope to keep pace with the daily increasing labours of this season of the year. Just now bedding out is the principal operation—work that whilst it lasts too often monopolises the entire labour of a garden, but for which there is no occasion if an early beginning be made, say early in May, and the hardy kinds be planted first, finishing up the tender sorts early in June. In this way time may intermittently be spared for hoeing and weeding shrubberies, picking off dead flowers and seed vessels from *Rhododendrons* and *Azaleas*, tying up perennials, clipping verges, weeding walks, mowing, and any other jobs that tend to the perfection of neatness.

INDOOR PLANTS.

PENTAS CARNEA.—Free-flowering, quick-growing plants like this well deserve cultivation. *P. carnea* strikes freely in the usual way in warmth if kept moist, close, and shaded. If cuttings are put in now they will make good flowering plants by the end of summer. Old examples well cut back now, if given moderate pot room, will push up a quantity of shoots that will flower in a short time, as every shoot produces bloom. It succeeds in any kind of tolerably good soil that is not too heavy.

PANICUM VARIEGATUM.—Wherever there is a stove or intermediate house, a good stock of this prettily variegated drooping plant should be grown; it looks well in hanging pots or baskets, and is never seen to better advantage than when forming an edging, so as to hang down in front of the side stages. A sufficient quantity of cuttings should be put in from time to time, as old plants get too large for some purposes.

REIDIA GLAUDESCENS AND GREVILLEA ROBUSTA.—These are two of the most elegant of all plants for table decoration or similar uses. The *Reidia* is somewhat tender, and on that account

best adapted for summer use; it strikes freely from cuttings, provided they are taken off with a heel when about 3 inches or 4 inches in length. They are best obtained by cutting off the heads of such old plants as have got bare at bottom; thus treated, they will quickly push out young growths if kept in a warm house; as the shoots get large enough to strike and are taken off, the old stems will go on breaking out afresh, thus affording a considerable stock before the end of the season. The *Grevilleas*, of which the variety just mentioned is the best for use in this way, will strike from cuttings procured and treated like those of the last named plant, but they are nevertheless best grown from seed, as in that way they make more elegant plants in a comparatively short time. Their leaves are not so persistent as those of some things; on the contrary, they fall off at the bottom and leave the base of the plants bare; on this account the stock should be kept up by successional sowings. Seeds put in now will soon germinate, and if well supplied with warmth and moisture will grow apace.

DATURAS.—Old plants of these cultivated in pots and wintered out of the reach of frost will have now broken into growth. If they are in want of more root room they must be shifted at once into larger pots or tubs, giving them good rich loam. Where there is a large conservatory to keep furnished, several of these showy plants may with advantage be grown so as to give a succession of bloom, which can easily be obtained by starting them at intervals. Those that commenced growth and which were potted earlier will now have got hold of the new soil, and should have plenty of air and light to prevent the shoots from becoming drawn, a condition in which they do not flower freely.

MIGNONETTE.—In large greenhouses and conservatories large examples of this plant are often preferable to small ones, and in order to have them of the required size and with the requisite amount of healthy foliage, they will require proportionate pot room, but with this plant we have not found it well to give too large shifts. It is better to move them frequently. *Mignonette* likes fairly rich soil, keeping the plants stopped as they require it; a good place in a light house or pit and plenty of air to insure stout leaves that will maintain a healthy condition are indispensable. Plants with indifferent foliage are unsightly however full of flower they may be. A little more seed may be sown now, and if well attended to the produce will yet attain a useful size. The new white variety is very beautiful; the flowers are individually very large and so double that it produces little, if any seed; it has therefore to be propagated by cuttings. For pot culture, however, this is no serious obstacle, and the plant has such a fine appearance that it deserves all the attention needful to insure success.

FUCHSIAS.—Certainly the most popular *Fuchsia* ever raised is *Mrs. Marshall*. It is the best market variety, and the way in which it is produced for sale in 4½-inch pots is marvellous, tens of thousands of plants 18 inches high, having from six to a dozen stems or shoots, all tied up to an erect position, each plant full of fine bloom. Then *Lady Heytesbury*, having a darker corolla and more massive tube, comes in for a limited share of culture. It is of the two, perhaps, the more pleasing flower. The plant produces but two or three more massive stems, but blooms freely when well grown. One other very handsome white kind is *Mary Queen of Scots*, the corolla of which is of a reddish hue. We like this kind very much, perhaps all the more that one does not see too much of it. Red kinds never are in such favour as white ones, and are sold usually in the proportion of about one to three or four early, but there is a larger demand later on. That grand double *Avalanche* is a favourite; so also is *War Eagle*, and *Black Prince* is another excellent sort. All these are now being pushed rapidly forward.

CINERARIAS.—Market growers of these spring decorative plants who have a good strain seem to be somewhat in advance of the ordinary florist and

seedsman in the matter of habit and quality, even though the latter no doubt strive to obtain good kinds. Somehow it appears to be the case that one or two men have in the market trade a good reputation for their strain of *Cinerarias* for a few years, then the mantle falls upon others; and thus, whilst a fine strain is always to be had, it is not always in the same hands. Dull colours, let the flowers be ever so good, are not in favour; rich reds and crimsons with a white centre and good dark selfs also are liked, because these kinds look unusually rich and telling under artificial light. Given flowers as large and rounded as a penny piece, plants from 10 inches to 12 inches high, and heads 12 inches across, and we get the ideal of a market *Cineraria*. Raised so easily from seed, it is one of the simplest to grow in all the florist's list, and as a rule sells well and is very profitable. The great fault of the average *Cineraria* is legginess. The German strain grown so well at Chiswick was dwarf and compact enough, but the flowers of very poor quality. A good selected strain would show something much better than those.

FRUIT.

ORCHARD HOUSES.—The weather at the present time is highly favourable to the colouring and ripening of Peaches and Nectarines in the early forced houses, and under the judicious use of water and liberal ventilation the flavour also should be good. When the fruit begins to soften for ripening, syringing may be discontinued and the supply of water to the roots considerably reduced, but at no time must watering be discontinued, as a flagging state of the tree will soon destroy the sprightly flavour if it does not lead to the premature ripening and dropping of the fruit. As safeguards, trees which have rooted into beds or borders should not be disturbed, as feeders of this kind always send up a steady supply; and the pots after being well watered should be heavily mulched to keep in moisture. When the time arrives for gathering the fruit, remove every Peach before it is ripe enough to fall from the tree, place them in shallow boxes well bedded with soft, dry Moss, and convey them to a dry, airy fruit room for use when in condition.

In the late or general house fruit of all kinds is now swelling away freely, and good syringing twice a day will be indispensable. Always use soft water if it can be obtained, and see that every part of the tree is well bathed, otherwise aphid and spider will soon attack the Peaches, Plums, and Cherries. Pay daily attention to pinching and thinning where strong upright growths are robbing the lower parts of the trees. Give an abundance of water to the roots, and add stimulants where feeding is considered necessary. As the fruit gets more advanced and the stoning process begins to draw upon the trees, frequent additions of the richest material to the mulching and constant feeding with warm, diluted liquid may be indulged in without fear of forcing a gross habit, as is sometimes the case when this treatment follows immediately after the flowering period. Thin out the fruit of Peaches, Nectarines, Pears, and Cherries where too thickly set, always bearing in mind that light crops of fine fruit give the greatest amount of satisfaction to producer and consumer, and pay best when sent into the market. If Strawberries still occupy the shelves, an effort should be made to keep them quite clear of the trees, and in a position favourable to copious feeding and good syringing without fear of injury to the permanent occupants of the house.

FIGS.—When all the fruit has been gathered off the early pot trees, the foliage must be regularly and copiously syringed to insure the destruction of any red spider which may have gained a footing. Old mulching may be removed, as far as practicable, without disturbing the surface roots, and a fresh supply of rich manure may take its place, to be washed in at future waterings. With the exception of the daily ventilation, which will be more liberal, the treatment of bringing on the second crop will be precisely the same as that

recommended for the first. As there is now little danger of fairly well-managed trees casting their fruit, a liberal hand must be directed to the thinning of the second crop, otherwise the Figs will be small, and they will ripen in a glut instead of giving a succession of full-sized fruit up to the end of the season. Trees permanently planted in succession houses will now take an abundance of water through the syringe, and good feeding with generous liquid will be imperative. Go over the trees once a week and thin out all superfluous growths. Keep all leaders neatly tied in, and guard against shutting out solar heat and light by allowing the foliage to become crowded. Many people make a rule of pinching the point out of every shoot to induce a fruitful habit; but this end can be much easier attained by annual lifting and replanting at the fall of the leaf by thinning out all shoots which have reached the extremity of the trellis at the winter pruning, and by laying in at full length the young growths of the current year. When treated in this way prolific kinds become perpetual bearers, as they are constantly growing and producing a young Fig at the base of every leaf.

HARDY FRUIT.—With the exception of Peaches and Nectarines, which are tolerably clean, fruit trees of all kinds are a good deal infested with grub, therefore timely and continuous hand-picking, supplemented by frequent washings with the engine, must be followed up until they are brought into subjection. By this time the disbudding of Peaches and Apricots will have been brought to a close, and healing in and the stopping of gross shoots will require attention. It is a common mistake to suppose that trees trained upon the full extension principle are very liable to rush into a too robust habit of growth, but such is not the case, at least in my experience, and it rarely happens that we find a single watery shoot in a tree which requires pinching to maintain the proper balance of the sap. If the broad copings have not been removed, frequent syringing will be necessary and highly beneficial to the fruit and foliage, and copious waterings on well-drained borders will be found a powerful aid in keeping the trees clean and healthy. Pears on south and west walls, also the most forward pyramids, will now be sufficiently advanced in growth to require attention to stopping and thinning. In years gone by it was the practice to allow a free and unrestricted growth of breastwood until the middle of July, but now we find the continuous pinching of the strongest shoots invigorates the weak ones and leads to the formation of blossom-bearing spurs, whereas the July pruning produces a violent check at a time when the half-swelled fruit is in the greatest need of encouragement. The early thinning of the fruit on Pear trees should not be entered upon rashly, as many promising fruits fall off after the inexperienced have set them down as safe; but heavily cropped trees may be relieved by the removal of all badly formed and inferior fruits, which cannot grow into value if allowed to remain.

KITCHEN GARDEN.

TOMATOES may with advantage be grown wherever there is a small portion of wall at liberty, as is often the case between fruit trees; a south wall is best, but they will frequently succeed on a western or eastern aspect. On the two latter we should recommend the greater part of the shoots being continually pinched in close, so as to bring them into bearing early. In all cases it is better to confine Tomatoes to a much less number of shoots than is often done, thereby enabling more plants to be grown on a given space. The thinner the shoots are kept the earlier they produce fruit. In warm districts Tomatoes will frequently succeed on a sheltered border fully exposed to the sun. Plant them out singly, using two or three sticks to each plant for support, to which they must be kept regularly tied as the growth advances; otherwise, from their fragile nature, they get broken by wind. Where they are so grown, the ground is better for being poor, as their natural habit of making too much

growth is still further increased where the soil is rich. The plants should stand about 3 feet apart each way, so as to avoid their shading each other. Brussels Sprouts should now be planted. They do not require so much room as winter Broccoli; but they must by no means be planted too closely, or they will never attain the vigorous hardy condition which alone enables them to withstand a severe winter. The character and condition of the soil in which they are grown has much to do with the space they should occupy. In good, well-manured land they should be put in 2 feet 3 inches apart each way; in shallow, poor soil they may be placed 6 inches closer, both in and between the rows. Move them, as far as possible, with their roots entire; and if the weather be dry, give them a good watering. Make successional sowings of Lettuce, and at this season it is a good practice to draw shallow drills 12 inches or 15 inches apart, and to sow the seeds in the bottom; the plants can thus be well soaked with water when they require it; advancing crops will be benefited by the application of manure water. Early crops of the Cos varieties should, as they approach maturity, be tied up with bast, which is of much assistance, even in kinds that are the most disposed to turn in their leaves and blanch naturally, and, moreover, it improves the quality. Amateurs who have not had much experience in Lettuce growing are apt to tie the ligatures too tight, which bruises the leaves and causes them to rot. All that is required is to draw the leaves together gently with the hand and tie them sufficiently close to exclude light. Keep the surface between advancing crops frequently stirred; and where the soil is of a retentive character, and was at all wet when dug, its condition will be greatly improved by forking it over to the depth of 6 inches or 8 inches, care being taken not to disturb the roots of growing crops. Small salads should be sown about once a fortnight, otherwise the supply will be interrupted. When the weather is hot and dry let such plants, and especially Radishes, be watered, or they will be tough and stringy.

KITCHEN GARDEN.

SPINACH AND ITS SUBSTITUTES.

AMONG the many garden esculents in common use during summer few, if any, give more trouble or are so difficult to provide as Spinach; no sooner do the plants appear above ground than they run to seed, and the leaves which one is then able to get are but few and small, stringy, and unfit to cook. These remarks apply to the ordinary variety, but fortunately there is what is called New Zealand Spinach, which forms an excellent substitute, and though, perhaps, not equal to spring and winter samples of the old kind, becomes valuable after this time of the year. The best way to get it early is to sow in pots, putting two or three seeds in each, when they should be placed in a Cucurbit frame or other warm place to get them to germinate, and grow the plants strong and large before turning them out. This may be done by the first or second week in June, but it is necessary to harden them off a little at first, so as to fit them to bear the change and exposure. As the habit of New Zealand Spinach is to spread, it requires some amount of room. A good place to plant it is on the top of any heap of waste soil or old exhausted hotbeds, or any position of that kind where it has plenty of room and something in the way of rotten manure or other rich material on which to feed. It may also be grown between trenches of Celery, but wherever planted the situation should be a hot, sunny one, or the progress of the plants will be slow. The only way of keeping up a supply of the old sort till the New Zealand comes in is to sow frequently on cool, shady borders or between rows of Peas, and that the leaves may be as large and succulent as it is possible to have them, the ground should be heavily manured and the plants thinned out to a good distance apart. One of the best, if not the best substitute for Spinach is the Silver Beet, which is quite worth sowing and growing, as during the

driest and hottest weather there are always plenty of fine juicy leaves to be had from it. Its culture is very simple; all that is needful is to draw a shallow drill, deposit the seed in it, and when the Beet comes up to thin the plants out, leaving them about 13 inches apart. S. D.

SPRING MUSHROOMS.

BY W. DELISLE HAY.

So far as the four seasons are concerned, we find that autumn is the one during which the largest number of Mushrooms are prevalent. In summer there are fewer, though the number is still considerable. In winter there are very few indeed; in spring a limited number. The Mushroom year may be said to commence in March, or as soon as frosts discontinue and the trees begin to bud. Each succeeding month shows a larger variety of species and a more widespread abundance of them, until September is reached, in which month Mushrooms attain their greatest degree of abundance throughout Northern Europe. Spring-time affords us a certain number of species, comprising several of the very best esculent kinds. Their growth at this season is somewhat scattered; that is, a good deal of country may be walked over before any are seen. Nevertheless, somewhere in every district specimens may be found, and frequently certain localities produce one species or another in very great abundance. Kinds, which I shall presently particularise and separately describe, ought to be sought after and brought into use. Annually they appear in no little profusion here and there throughout the country, and are suffered to grow unheeded and to rot where they grow. This is a great pity, especially as regards two sorts in particular—the St. Georges and the Morels—which are exceptionally valuable, both as regards richness of flavour and nutritive excellence. In France, Germany, Italy, and indeed throughout Europe generally with the exception of these islands, the St. Georges and Morels have some commercial importance. They are rarely used by the peasantry who find them, being esteemed so highly by the wealthier classes that they will always fetch a high price in the markets. Here, of course, our insular prejudice prevents them from having any markets at present.

MORELS.—Botanically considered, the genus *Morchella* is removed to some distance from the genus *Agaricus*, which latter, being typified in the Mushroom commonly cultivated and eaten in this country, will be more familiar to us. The genus *Agaricus* belongs to the great order of *Agaricini*, in which the distinctive feature is an array of laminae, or gills, which are disposed on the under surface of the cap. Upon these gills is produced a fine dust composed of numerous infinitesimal bodies called spores. These are the fructifying agents. Now in the order of *Elvellacei*, to which *Morchella* and kindred genera belong, the fructifying surface is the whole exterior, or upper surface of the part corresponding to the cap. There are no gills, as in the *Agaricini*; nor are there tubes, as in the *Polyporei*. These different features form great dividing lines, by which mycologists have found it possible to classify the innumerable species of Mushrooms. Other grouping, which need not be further referred to here, is effected by means of a microscopic examination of the spores. This places the *Elvellacei* and *Agaricini* still further apart. There are a considerable number of orders, each containing various genera, and characterised by the different formation of the fructifying part. Thus, for example, there is the order of *Hydnei*, in which prickles or spines take the place of gills; the order of *Trichogastres*, comprising the Puffballs; the order of *Tuberacei*, to which the Truffles belong; and so on. All these that I have mentioned contain species which are esculent, besides others which are not, and yet others which are poisonous. The Morels are terrestrial fungi—Mushrooms growing on the surface of the ground. There are various species of this genus occurring in sundry parts of Europe, Asia, and America. They are much sought after, and esteemed as

delicacies in many countries. All of them appear to be wholesome, and well fitted for food. In Britain we have three species, *M. esculenta*, *M. crassipes*, and *M. semilibera*, to which a fourth, *M. patula*, may perhaps be added. In qualities these species are nearly identical, and as their appearance is also very similar, they may practically be regarded as the same plant, so far as our present purpose extends. The Morels are essentially spring Mushrooms. They may appear as early as the beginning of April if the weather is mild, and they are rarely seen after the middle or end of June. The localities they affect are generally damp grassy places in and about woods, corners of fields, in parks, &c. Here they spring up in groups, sometimes small and scattered, at other times in very extensive lumps. They may be recognised by the following characters: A stem which is thick, smooth, dirty white in colour, 1 inch or 2 inches high, supports a soft lumpish cap. This cap is white grey in young plants, becoming grey-brown in older ones. It is irregularly rounded, its tendency being to a conical shape, but this may be modified by the grass or roots through which it has pushed its way upward. The surface of the cap is deeply pitted or honeycombed with small, irregular, polygonal cells. On cutting the Morel into vertical halves, the interior of stem and cap is found to be hollow, the latter being attached to the stem at the sides, and not fixed upon a central support, as in typical *Agarics*. The smell is slight and agreeable. The whole plant attains 3 inches or 4 inches of height, and 2 inches or 3 inches in greatest diameter of cap. *M. crassipes*, however, sometimes grows to a considerably greater size. As regards

THE CULINARY PREPARATION OF MORELS, the first process is to remove the base of the stem, and to pick as clean as possible from adhering dirt. They should then be cut open and freely washed and rinsed in hot and cold waters. When quite clean they are to be thoroughly dried by lightly pressing in a soft napkin. There are many ways of cooking them. The simplest is to stew them in a little butter and broth with sweet herbs and condiments, giving them about an hour on a slow fire. This ragout may be improved, if desired, by the addition of a glass of wine, rich gravy, cream, minced veal or ham, or so forth; and it may be finally "bound" or thickened with egg yolk and turned out upon fried bread. Morels are so good that they fully deserve any extravagance of cookery that the means of the kitchen afford. Another mode consists in filling each Morel with stuffing of various kinds, wrapping in fat bacon, tying the parcel together, and then stewing as before; or the halves may be skewered with alternate slices of bacon, and may then be stewed or grilled. Large Morels may be also buttered, seasoned, doured, and then simply grilled or baked in a Dutch oven. If a quantity of Morels are gathered, which should be in dry weather, it may be well to preserve some for future use. After cleansing, washing, and drying, they should be allowed to lie before the fire a few minutes until the superficial moisture has evaporated. They are then to be cut in pieces and placed in some situation where they are exposed to a current of warm, dry air. In a day or two they will be shrivelled and dry, and may then be gently heated in a cool oven, and finally put away in tins with a pinch of spice. Before these are wanted for use they should be soaked for some hours in tepid milk, and may then be cooked like fresh ones, or may be added to various meat dishes. Morels abound in many parts of the country during their season. I have sometimes seen clusters containing 20 lbs. weight or more of them. As in flavour they are scarcely inferior to the much-prized Truffles, the quantities annually produced in this country certainly ought not to be lost.

DRIED MORELS have been sometimes imported from abroad by Italian warehousemen, to be used here as flavouring ingredients by foreign cooks. It is a mistake, however, to employ the Morel as a mere adjunct or condiment to a dish, and the same might be said with regard to Truffles if they were more plentiful. Morels ought to form the basis

of any dish into which they enter, and in fact constitute it of themselves. This is because of their nutritive properties, apart from the fact of their gustatory excellence. Recent chemical research has demonstrated that the dry solid matter of the Morel contains 36.25 per cent. of proteinaceous compounds, that is of albumen, gluten, and the like, nitrogenised principles which are the "flesh-and-blood-making constituents" of food. The Truffle contains 35 per cent. of these. It is thus evident that these Mushrooms are actually of higher nutritive value than Lentils, Beans, Wheat, and all the vegetable aliment we commonly make use of. This is a fact worth attention, and it may be mentioned in addition that the Morel is certainly very easy of digestion. All esculent Mushrooms appear to be of very similar composition, so far as they have yet been examined. The nitrogenous principles, however, which give them their nutritive value are contained in different species in varying proportions. The field Agaric, commonly eaten in Great Britain, possesses much less proteinaceous matter than the Morel, which, indeed, seems to be the most valuable of all Mushrooms in this respect. In my opinion, strenuous exertions should be made to ascertain some means by which this exceptionally excellent Mushroom might be cultivated.

HELVELLA is a genus closely akin to *Morchella*, and belonging to the same order. The various species which are members of it are not, however, all spring Mushrooms, though they seem to be all edible. I note only two that are found at the same season as the Morels, and these, disappearing in summer, are found again from September to November, when the rest of their congeners are also prevalent. The two spring Helvels are *H. gigas* and *H. lacunosa*. The first is of larger size, and its colour is generally paler than that of the second. Otherwise they so nearly resemble each other, that I may venture to describe them together. The stem is about 2 inches high, thick, and of a dirty white colour. Instead of being smooth like the stems of Morels, it is fissured with deep longitudinal cavities, which give it the appearance of several slender stems twisted up together. It is not hollow within, but when sliced the fissures are seen to run throughout the structure. The cap which rests on this stem is grey, brown, or dull black. It is a loose pendulous structure, lobed and inflated, crumpled up in all sorts of ways. It is not a hood with a cavity inside, like the cap of Morels, but on examination looks as if it had been intended to be flat and smooth, and had by some accident got wrinkled and contorted anyhow. Often it has a vague resemblance to a bishop's mitre, being divided into two or more erect lobes. To get a rough idea of what a Helvel is like, take a piece of Cabbage-stalk 2 inches or 3 inches long, twist it till it splits, and set it end up on the ground. On the top of this stick the palm or back-piece of an old kid glove, having crumpled it up into a shapeless ball in the hand. Rude though this illustration may be, I think it will convey a notion of what a Helvel is like. These plants have a faint odour, something resembling that of tan or new leather. They grow on the bare ground, or amid Grass, Fern, or Moss, and always in damp shady places. They are found in woods, copses, corners of fields, under trees and hedges, and in many waste places and woodside nooks. They may be eaten without fear whenever found, as there is nothing else at this season which resembles them more closely than Morels, no poisonous fungus at any rate, unless it be one which I shall refer to next. Care must be taken not to use these, or indeed any sort of Mushroom whatsoever, when they have at all begun to decay or putrify; and when soaked with water, as in rainy weather, they are scarcely fit to cook. Helvels are very nice, and they may be dressed in various ways like Morels. The same recipes answer for both. Only in one thing need there be any difference. Helvels will not bear much washing, as it tends to carry away their delicate flavour. They should be picked clean by hand, and lightly touched with a soft brush or wiped with a damp cloth. They may be just quickly rinsed in cold water and immediately shaken dry

in a soft cloth. When this has been done, cooking may be proceeded with in similar modes to those used for Morels. Generally they require a somewhat shorter time, but this depends a good deal on the size of the specimens operated upon. Helvels may be readily dried for storage the same way as Morels, and are then scarcely inferior to them.

THE LORCHEL.—This is a German name for this spring Mushroom, which has no English name. Formerly it was classed with the last-named genus under the scientific name of *Helvella esculenta*. It is not a true Helvel, however, so mycologists have now decided to place it in a genus by itself, which comes between those of *Morchella* and *Helvella*. The scientific name of the Lorchel, therefore, is now *Gyromitra esculenta*. The points distinguishing the Lorchel from both the genera just named may be easily understood and recognised. The stem is short, 1 inch or 2 inches high, and evenly cylindrical; it is smooth, not fissured as in the Helvels, somewhat downy, and of a pinkish white. The cap is of a bay-brown colour and irregularly rounded, being up to 2½ inches or 3 inches in diameter, vertically or across. There are no pits or cells upon its surface, as in the Morels, but this is smooth. Nor are there the loose, thin, wrinkled, or lobed folds of the Helvels. The cap of the Lorchel presents smoothly folded plaits or sinuous depressions, often reminding one of the foldings of a turban. On cutting open the Lorchel its interior is seen to be partially hollow, sinuous cavities and solid substance dividing them. On discovering this Mushroom, we should see that its smooth cap and stem, and the substantial nature of the first, were points unlike a Helvel. Then the absence of the honeycomb-like pits on the cap would equally assure us it was not a Morel. The plant would thus at once be identified as what it is, and nothing else. The Lorchel has a faint, agreeable odour and a pleasant taste when raw. Cooked, it makes appetising dishes, and has always been much esteemed abroad. A *gourmet* would say that it was inferior in richness of flavour to the Morels, but for all that it is not to be despised. In Germany it is particularly esteemed, and is one of the commonest Mushrooms brought to market. Popularly there it is confounded with Morels, and probably also with Helvels, all being sold and eaten together, and having the name of "Morchel" applied to them in common. The Lorchel grows in clusters and tufts in and about woods, those of Pine and Fir in particular, and in shady grassed hollows on elevated ground. It is plentiful enough in some parts of Europe, but has been accounted a rarity in Britain. Of late years, however, it has been found in several parts of the country, and in not inconsiderable quantities. Very likely it is by no means so scarce as has been supposed. There are very few people that take any observation of fungi, and most of our Mushrooms, the best and worst alike, annually perish without a hand to gather them, or a single eye upon them which could tell what they were. This is the

SEASON FOR THE LORCHEL, which is found from April till early in June. In spite of the testimony of its designation "*esculenta*," which proves that it has been known and used as an edible from long past times; in spite of its great popularity on the Continent, its large consumption and agreeableness of flavour, there has always been a certain dark suspicion attached to this Mushroom. Poisonings, more or less serious, have been traced to it. At first, no doubt, these were attributed to Morels and Helvels with which the species was confounded. But, as the distinctions of species came to be better understood, suspicion was narrowed down until it rested entirely upon the Lorchel, and not upon the others. Yet it could not be stated how it was that a plant much eaten in many districts, and usually found a pleasant and wholesome food, should sometimes prove noxious. Authorities were fain to take refuge in the vague assertion that "under certain unknown conditions the Lorchel occasionally became poisonous." It remained for Dr. Ponfick, a professor in Breslau University, to demonstrate last year the true state of the case, to show the nature of the noxiousness

due to the Lorchel, and to show also how its hurtfulness was to be overcome. Lorchels, he says, are poisonous, but cooking deprives them, more or less, of their poisonous qualities. The repeated washing with cold water which they usually undergo to clean them takes away a portion of the poison, and boiling does the rest; but the water in which they have been boiled is highly poisonous, and should always be carefully got rid of. We had something of an anti-Mushroom panic last year, induced by the lamentable death of an English clergyman through poisoning, in consequence of his having partaken of some noxious Mushroom—species unknown. But because one man may be killed by eating Hemlock, it is no reason why we should condemn the innocent Parsley; and so, likewise, because one kind of Mushroom is shown to be poisonous, that is no reason for condemning others equally well proved to be sound and wholesome food. Dr. Ponfick informs me that of other Mushrooms used as esculents besides the Lorchel, and which he has similarly tested and examined, he has in no case found any noxious principle whatever, as in the case of that one—*Gyromitra esculenta*. Small quantities of Lorchels, however, produce no injurious effect when eaten. But if an amount equivalent to 1 per cent. of the weight of the body be consumed, symptoms of poisoning surely supervene. If the amount eaten be increased to a variable quantity of from 1½ to 2½ per cent. of the body-weight, a fatal result is inevitable. From this it may be gathered that if an adult man were to eat Lorchels to the amount only of half a pound or so at a meal, he might possibly experience no ill effects from them; but were he to consume 1 lb. or 2 lb., he would undergo severe symptoms of poisoning; and a larger amount—taking possibly not all at once, but within twenty-four hours say—would be likely to cause a fatal result. It is to be remembered that these figures have reference only to the Lorchel when raw. Ordinary preparation and cooking cause a decided diminution in the degree of virulence possessed originally by the Lorchels. From that fact, also to the large quantity that must be consumed in any case before symptoms of poisoning would show themselves, has arisen the circumstance that the Lorchel usually produces no ill effects. Seldom would it be consumed raw or to such a considerable amount; and so it happens that it has been for many generations considered a harmless esculent, and largely used as such in many parts. In

CONTINENTAL COOKERY it is usual not merely to wash all kinds of Mushrooms in cold water before proceeding to cook them, but also to "blanch" them by throwing them for a minute or two into boiling water. Whatever may have been the original motive for this process, it has now become clearly evident that it is to some extent a safeguard against poisonous species. The noxious principle of the Lorchel is certainly removable by boiling water; and I may state, on the authority of other experts than Dr. Ponfick, that the poisons existing in some other species have been also ascertained to be removable by the same means, *e.g.*, the dangerous Amanites and certain other Agarics. Still, I would not advise the universal application of this method, since it deprives some delicate and perfectly wholesome kinds of their flavour. It is far better to understand how to make proper distinctions between various species, and to give to each just such preparation as it particularly needs. The conclusion arrived at by Dr. Ponfick is that the Lorchel (*Gyromitra esculenta*) ought never to be eaten raw, nor, indeed, in any way until it has been subjected to the absolutely necessary preparation. It is to be cut into several pieces, carefully boiled, and washed in several renewed quantities of hot water. It is lastly to be thoroughly dried by shaking and handling in soft cloths; then it may be cooked in any way like Morels or Helvels.—*Field*.

HARICOT BEANS.—These are but a variety of the common French Bean, and need just the same cultivation. The Beans are allowed to hang and ripen, when the matured pods are gathered and shelled.—A. D.

ASPARAGUS OR BUDA KALE.

IF asked which I found to be the most profitable quarter in the kitchen garden during winter and spring, say from February to the end of May, I would unhesitatingly decide in favour of that devoted to Asparagus Kale. In fact, but for this kind we should have had no greens for a considerable time this spring. Brussels Sprouts, Broccoli, Scotch Kale, and Cabbage were not proof against first the continuous heavy rains and subsequently the cold frosty winds, and none of them have succeeded at all well. Asparagus Kale, however, is not easily destroyed or materially checked in growth, and we have been able to gather immense quantities of really delicious greens from a comparative small piece of ground. There appears to be different forms of it, one being tall growing and two others dwarf in habit, varying only in colour. Of the latter we grow the darkest and presumably the

early Potatoes, Strawberries, Peas, or Turnips is cleared off. It really deserves better management, but space is limited, and it must be treated as a successional crop. Last season the stock was planted immediately after a breadth of early Strawberries was cut away, the ground being merely hoed over and all rubbish burnt. Drills were drawn with a heavy hoe midway between the old Strawberry lines, these being 30 inches apart, and the Kale plants were transplanted with a good ball of soil about the roots, and disposed 2 feet asunder in the rows. In dry seasons in similar cases we find it necessary to repeatedly fill the drills with water till thoroughly soaked, substituting, when possible, liquid manure at the last soaking. This facilitates planting, and besides insures a good start. The drills are kept open, as water has to be given occasionally till the plants are well established, the soil being then levelled over after

rows of Peas, as just advised, instead of Spinach, which during hot weather seldom proves profitable. In

PREPARING ASPARAGUS KALE FOR THE TABLE, we do not trim the leaves off the stalks, cooking and eating them, under the impression that they are equal to Asparagus. They are decidedly very succulent and good, but are cooked with the leaves as other Kales are, and in this manner we have a wholesome "second vegetable," and one of which we never tire.

GROWER AND EXHIBITOR.

BOOKS.

THE GOLDEN CHERSONESE.*

"THE Golden Chersonese" is a rather far-fetched name for the British state of Perak, on the Malayan Peninsula, a great slice of forest land

Chinese houses and Malay bathing shed, Kangsa River.

hardest, and this is fully equal in quality and quite as prolific as that with green stalks and leaves. The latter, however, is the best for the markets, the buyers in this and in many other cases being influenced by colour. I do not depend upon seedsmen for the seed, but annually save a few strong plants to produce seed for myself and friends, and I consider that I am right in so doing. As an inducement to others to plant Asparagus Kale extensively, I may mention that I sent a quantity of seed of it to a market gardener friend, and this spring he had four acres of capital Kale, for which he declined an offer of £25 per acre. This has certainly been an exceptional season, but as this Kale, if kept closely picked, is at its best long after the majority of greens have run to seed, it would no doubt seldom fail to fetch remunerative prices. At any rate, it should be

GROWN IN EVERY GARDEN in proportion to the demands of the establishment, and it is, in addition, quite a poor man's vegetable. It is easily grown. Our seed is generally sown early in April, the plants being now just pricked out, and will not be finally transplanted till a crop of either

the last watering that is considered necessary. Firm ground is selected, and the same method of planting is adopted in the case of much of the Broccoli grown here, for the well-known reason that sturdy, and therefore more hardy, growth results than is the case where loose ground is devoted to them. The Asparagus Kale being hardier than Broccoli, the latter in small gardens should preferably have the most open sites as well as firm ground. For instance, they may be planted between the widely dispersed rows of Potatoes, or in succession to Strawberries, early Peas, and Beans, while the Kale will grow freely and yet be hardy if planted between the rows of main crops and late Peas, among fruit trees, and in other positions unsuitable for many other crops. As it is getting late to sow the seeds of any kinds of winter greens, including Asparagus Kale, I should advise those who may feel disposed to give this Kale a trial to sow the seed thinly in drills where the plants are to remain. If the rows are drawn about 2 feet apart, and the plants eventually thinned to about 15 inches asunder, the ground in all probability will be well covered and a profitable crop realised. Seeds may thus be sown or plants be dibbled in between the

and mountain country in the Tropics near the line, now very ably presided over by Her Majesty's Resident, Mr. Hugh Low. This classic region seems to be the Aurea Chersonesus of Ptolemy, the Golden Chersonese of Milton, and the Malayan Peninsula of our own day. It is the home of the Malay and wild men or aborigines called Jakuns who formerly built their rude habitations in trees, as some security from the tigers and reptiles of the jungle, and, so far as we know, this habit of constructing arboreal homes (not far in advance of those which the Orang-utan makes still) may have been the origin of the pile dwellings now common not only in the Golden Chersonese, but throughout the Malayan Archipelago, and also in the Sula Isles, the Celebes, and in New Guinea. These houses, thatched with Palm leaves and having gridiron-like floors made from the wood of the Neibong Palm (*Oncospermum filamentosum*), are built over the river mouths and inland lakes by the coast-dwelling Malay, and even inland

* "The Golden Chersonese." By Isabella L. Bird (Mrs. Bishop). London: John Murray, Albemarle Street. 1883. With maps and illustrations.

we find the Dyaks, or aborigines, also adhering to the old custom, although there is now no danger from animals or reptiles, so that in their case good drainage and immunity from ground damp, together with a more perfect system of ventilation, may be taken as the inducement to keep to a system of rustic architecture so primitive and at the same time so widely spread. Aboriginal man in the Malayan region is to-day living in what to the more northern races is the far distant past. Although he now knows how to build good serviceable sea-going prahus, or boats, yet the primitive dug-out canoe made from a single tree's trunk is commonly employed for river work. Again, while his women can weave the strongest of cloth fabrics from the tough hemp-like fibres of *Curculigo latifolia*, yet inland are the "Fig leaves" still worn as the only clothing in the shape of a waist cloth, made from the soaked and beaten out bark fibre or bast tissue of *Artocarpus elastica*, a tall growing tree of the Bread fruit family. Here in the "Gardens of the Sun" we yet have a people living in primitive simplicity, and employing the utensils, fabrics, implements, weapons, and customs belonging to bygone ages. In the case of Europeans, these have survived untouched or nearly so by the civilisation of Egypt, Greece, or Rome, or even of our own time. It has been said that our English civilisation and British rule are octopi which stretch their tentacles over the whole world, but at present they have barely touched these beauty spots in the China seas, where mankind is yet strikingly primitive and Nature alike generous and supreme.

"THE MALAYAN PENINSULA," says Miss Bird, "is a gorgeous tropic land, and with its bounteous rainfall and sunshine brings forth many of the highly prized productions of the Tropics with some that are peculiar to itself. Its botany is as yet very imperfectly known. Some of its forest trees are very valuable as timber, and others produce hard-veined woods which take a high polish. Rattans, Malacca canes, and gutta are well known among its forest products, gutta with its (now) extensive economical uses having been used only for Malay horsewhips and knife-handles previous to 1843. The wild Nutmeg is indigenous, and the nutmeg of commerce and the clove have been introduced and thrive. Pepper and some other spices flourish, and the soil, with but a little cultivation, produces Rice, wet and dry, tapioca, gambir, sugar cane, coffee, tea, cinchona, india-rubber, and indigo. Still it is doubtful whether a soil can be called fertile which is incapable of producing the best kinds of cereals. European vegetables are on the whole a dismal failure." Miss Bird here seems to lay the blame, which rightly belongs to the action of a tropical climate, upon the soil, which in reality differs but little in its powers of production all the world over; and it is an open question as to whether Rice is not after all the best of all cereals—certainly it is the most suitable for tropical culture. Some few preliminary chapters relating to Hong-kong and Canton might well have been omitted, since the information given is neither new nor particularly entertaining, and why this experience in Cathay should be sandwiched into a book on the "Golden Chersonese" is not quite clear, nor can we admit that Singapore, the seat of government of the Straits Settlements, comes well within the Golden Chersonese, curiously comprehensive as that title may be. At page 107 we are told that Singapore "is hot, so hot, but not stifling," and yet on page 111 the residents are alluded to as a "parboiled community." When, too, we are told that the Killarney Fern (*Trichomanes radicans*) drapes the rocks in the Golden Chersonese, we doubt the teaching of our fair authoress from a botanical point of view, and we more than doubt her statement (p. 135) that the Dove Orchid (*Peristeria elata*) is found wild in Malacca. Miss Bird describes it as "an Orchid which lives but for a day, but in its brief life fills the air with fragrance." Perhaps *Dendrobium crumenatum* is the Orchid intended; at any rate the *Peristeria* is a native of Panama. When we are told that "the banana unfolds its gigantic fronds above its golden fruitage," we recognise graceful poesy of

style, but the leaf of a Banana is not a "frond." The use of capital letters, too, for names of plants is most erratic—sometimes capitals, sometimes not—indeed, slips and errors are abundant—nothing, it may be said, very bad, but then our authoress is no new hand at literary work, and therefore we have a right to expect something better than slipshod writing. When we compare this book with another of Mr. Murray's entitled "A Lady's Travels Round the World," we are struck by its *blasé* character. It has a clever professional tone about it, but no freshness, nothing spontaneous, no originality of idea; in a word, we are disappointed with the "Golden Chersonese," and do not think that it will in any way enhance the fame of an authoress who has already written considerably better books.

The general get up of the work is satisfactory, and the illustrations are also good, but we are a little surprised to find no acknowledgment, no intimation even, that three or four of the best blocks are borrowed from Burbidge's "Gardens of the Sun." Even in these days of "book making" there now and then exists such a thing as courtesy between the needy borrower and the willing lender of literary material, and in matters of this kind the borrower loses nothing by being generous. To ordinary readers we doubt not Miss Bird's latest work will prove an interesting one; but those who have read what St. John, Wallace, Jager, Major McNair, and Burbidge have told us already of the Malay and other races in the Golden Chersonese and Malayan Archipelago, will be disappointed to find much information that is necessarily old to them, cleverly dished up again under a new title. Miss Bird has no claim to scientific accuracy; but we are quite sure she could have made this last attempt at book-making much better if she had really tried to do so. We shall only take one more extract, and that to show how innocently our travelled authoress ignores the distinction between tropical forests and tropical jungle—jungle being the weedy after-growth which springs up after fires or clearings have destroyed the forests or woods primeval.

"The Linggi above Permatang Pasir, with its sharp turns and muddy hurry, is, I should say, from 30 feet to 60 feet wide, a mere pathway through the jungle. Do not think of a jungle, as I used to think of it, as an entanglement or thicket of profuse and matted scrub, for it is in these regions at least a noble forest of majestic trees, many of them supported at their roots by three buttresses, behind which thirty men could find shelter. On many of the top branches of these other trees have taken root from seeds deposited by birds, and have attained considerable size; and all send down, as it appears, extraordinary cylindrical strands from 2 inches to 6 inches in diameter, and often 150 feet in length, smooth and straight until they root themselves, looking like the guys of a mast. Under these giants stand the lesser trees grouped in glorious confusion—coco, sago, areca, and gomuti palms, nipah and nibong palms, tree ferns 15 feet and 20 feet high, the bread-fruit, the ebony, the damar, the india-rubber, the gutta-percha, the cajuput, the banyan, the upas, the bombax or cotton tree, and hosts of others, many of which bear brilliant flowers, but have not yet been botanised; and I can only give such barbarous names as chumpaka, Kamooning, marbow, seum, dadap; and, loveliest of all, the waringhan, a species of ficus, graceful as a birch; and underneath these again great ferns, ground orchids, and flowering shrubs of heavy, delicious odour, are interlocked and interwoven. Oh that you could see it all! It is wonderful; no words could describe it, far less mine. Mr. Darwin says so truly that a visit to the tropics (and such tropics) is like a visit to a new planet. This new wonder-world, so enchanting, tantalising, intoxicating, makes me despair, for I cannot make you see what I am seeing! Amidst all this wealth of Nature in this perennial summer heat I quite fail to realise that it is January, and that with you the withered plants are shrivelling in the frost-bound earth, and that leafless twigs and the needles of half-starved pines are shivering under the stars in the aurora-lighted winter nights.

"But to the jungle again. The great bamboo towers up along the river sides in its feathery grace, and behind it the much-prized Malacca cane, the rattan, creeping along the ground or climbing trees and knotting them together, with its tough strands, from 100 feet to 1200 feet in length, matted and matting together; while ferns, selaginellas, and lycopodiums struggle for space in which to show their fragile beauty, along with hardier foliaceous plants, brown and crimson, green and crimson, and crimson flecked with gold; and the great and lesser trees are alike loaded with trailers, ferns, and orchids, among which huge masses of the elk horn fern and the shining 5-foot fronds of the *Asplenium Nidus* are everywhere conspicuous. Not only do orchids crowd the branches, and the *hoya carnosa*, the yam, the blue-blossomed *Thunbergia*, the vanilla (?) and other beautiful creepers, conceal the stems, while nearly every parasitic growth carries another parasite, but one sees here a filament carelessly dangling from a branch sustaining some bright-hued epiphyte of quaint mocking form; then a branch as thick as a clipper's mainmast reaches across the river, supporting a festooned trailer, from whose stalks hang, almost invisibly suspended, oval fruits almost vermilion coloured; then again the beautiful vanilla and the *hoya carnosa* vie with each other in wreathing the same tree; or an audacious liana, with great clusters of orange or scarlet blossoms, takes possession of several trees at once, lighting up the dark greenery with its flaming splotches; or an aspiring trailer, dexterously linking its feebleness to the strength of other plants, leaps across the river from tree to tree at a height of 100 feet, and, as though in mockery, sends down a profusion of crimson festoons far out of reach. But it is as useless to attempt to catalogue as to describe. To realise an equatorial jungle one must see it in all its wonderment of activity and stillness—the heated, steamy stillness, through which one fancies that no breeze ever whispers, with its colossal flowering trees, its green twilight, its inextricable involvement, its butterflies and moths, its brilliant but harsh-voiced birds, its lizards and flying foxes, its infinite variety of monkeys—sitting, hanging by hands or tails, leaping, grimacing, jabbering, pelted each other with fruits; and its loathsome saurians, lying in wait on the slimy banks under the mangroves. All this and far more the dawn revealed upon the Linggi river; but strange to say, through all the tropic splendour of the morning I saw a vision of the Trientalis Europea, as we saw it first on a mossy hillside in Glen Cannich."

Calavanches.—Its botanical name is *Cicer arietinum*, the Chick Pea, interesting to classical scholars as the derivation of Cicero's family name, as the Pisones derived theirs from the *Pisum* or Pea, and the Lentuli from the *Lens* or Lentil. The correct Spanish name is Garbanzo (pronounced Garbantho). In Spain it plays somewhat the same part as a national dish as the Potato does in Ireland. It is seldom cooked by itself, though there is no reason it should not be, being of excellent flavour and different from our common Pea, but is chiefly used as one of the ingredients in the far-famed olla podrida, a dish composed of different sorts of meat boiled together, though in practice generally consisting of small dice of bacon with Garbanzos, and any other vegetables sliced, and then stewed slowly for hours; a dish partaken of with relish repeatedly by the writer when in Spain. The Chick Pea as grown in Spain would form a valuable addition to our bill of fare. It is largely cultivated in India as well as in the south of Europe, but it is of too delicate a nature to be grown advantageously in this country. The seeds are sometimes parched for use on journeys, and also made into cakes and puddings, whilst a kind of sweatmeat is made of them in India with sesame oil and sugar. The pods are hairy, and exude an acid which irritates the hands and is injurious even to the boots of persons walking through a field where they are grown, the acid being collected by the natives in India for medicinal purposes. In the fourteenth century our forefathers

used Vetches, then called Chych, but the exact nature of the plant meant is not certainly known.—W. W.

TREES AND SHRUBS.

BUILDING WOODS.

THE first importations of foreign-grown building woods to this country marked, says the *Builder*, a new and distinct era in the employment of timber as a constructive material. The early arrival of foreign building woods first reached us from Russia, and they came over in such limited quantities that the vessels which conveyed them across the Baltic were usually loaded to the extent of at least three parts of their carriage capacity with linseed or some other commodity. How far the importation has since then progressed may be best inferred from a reference to the following table, which shows the extent of last year's exportation from the wood-growing countries abroad to the United Kingdom:—

	Loads.
Norway and Sweden	2,022,472
British North America	1,292,663
Russia	1,160,050
Germany	224,205
Other countries	835,756
Total	5,535,146

It may be remarked that there are in the United Kingdom 118 ports into which foreign building timbers are imported, and to illustrate the important position which London occupies as a timber port, it need only be said that during 1882 London alone received 1,404,793 loads, or, in other words, more than a fourth of the total quantity imported into the United Kingdom. In the early days of the importation of foreign building timber, native woods competed with it for supremacy, or rather struggled to prolong existence. The issue of the struggle was not, however, long in declaring itself for the foreign material, and it will be a matter for satisfaction for those who appreciate good work to know that it is almost the unanimous opinion of wood dealers that the days for importing wood of common quality are practically gone by. The tendency to use superior material, or rather the disinclination to make use of very inferior, appears to be quite a modern one. It is surprising that so little attention has been paid to the seeking out of coloured woods for cabinet purposes. The varieties of trees in the rich tropical forests of Central America are to be counted almost by the hundred, and yet we see the general consumption of cabinet woods restricted to some few varieties, such as Oak, Mahogany, Rosewood, Ebony, Satinwood, &c., including the wood which has recently met with such great favour—American Walnut. The early importation of "fancy woods" has been added to but little, so far as additional varieties are concerned. Yet the increased desire for superior building woods is pretty certain to finally take the direction of making "fancy woods" more popular for better class joinery work, and when this innovation has become completely established, we shall, without doubt, find a desire spring up to secure woods of various hues and kinds. A remarkable circumstance of modern times relating to building woods has been the sudden popularity attached to Pitch Pine, which not many years ago was almost contemptuously despised. This suddenly-acquired popularity is to be accounted for by reason of the Corinthian order, of large dimensions, being in vogue, the construction of which is simple and the general effect excellent. W. C. T.

Furze and its varieties.—The Furze, Whin, or Gorse, as it is called in different localities, is at present one of the most showy of flowering shrubs, and one that, common though it be, is remarkably effective even in gardens, when judiciously placed, on a little knoll for instance, as it withstands drought and exposure well, and during spring will form quite a golden mass, especially if the double-flowered variety is used. This

differs from common Furze in being dwarfer and more compact, forming as it does dense bushes. A kind named *Ulex europæa nana* is dwarfer, rather more straggling, and less floriferous than the common kind. The Irish Furze (*U. europæa stricta*) is a very distinct variety, but flowers sparingly. What is known as the Spanish Furze (*Genista hispanica*) is also a pretty free flowering little shrub. It forms a dense, globular, prickly mass, and is rather later in flowering than the double Furze.—ALPHA.

WEBB'S INDIAN FIR.

(*PICEA WEBBIANA*.)

THIS is a distinct and beautiful species of Silver Fir, indigenous to the Himalayas, where it forms vast forests, and attains an average height of about 100 feet. In this country it is liable to be cut down by late spring frosts, yet in places where it succeeds it has proved to be one of the finest conifers of recent introduction. It is sometimes confounded with *P. Pindrow*, both being natives of the same place, and rather tender. They are, however, not only quite distinct species, but also dissimilar in colour, habit of growth, and general appearance, so that it is not easy to understand how the mistake has occurred. In this country it thrives best when planted on a north exposure, partly shaded from the morning and noonday sun by deciduous or other trees, and in places where it does succeed it is really a handsome and highly ornamental tree. Its habit of growth is strictly conical, and the branches are arranged in regular whorls around the stem. The leaves are about 2 inches in length, of great substance, and arranged in two rows; their upper surface is a rich glossy green and that underneath silvery. The cones are fully as large as those of *P. nobilis*, and of a pretty purple colour, and as they stand erect on the branches, they are seen to good advantage. Like, however, many other rare conifers, it seldom produces male flowers in this country, and therefore one has no opportunity of raising plants of it from home-saved seeds. I have, however, propagated it to a limited extent by layering the lower branches. It should never be planted on flat, soft, boggy soils, as the young wood produced under such circumstances being generally of a soft character, never gets thoroughly matured; consequently it is easily cut down by spring parts. In the spring of 1861 and again in that of 1867 we lost several fine young trees of this Fir growing under conditions similar to those just mentioned.

SOIL.—As far as my experience goes, it should be planted on a loose, open gravelly or clayey soil, the constituent parts of which consist principally of inorganic matter, resting upon a cold clay well broken up and thoroughly drained. The young wood produced on such soil is much firmer, ripens better, and is not so liable to be injured by frost as that produced by trees growing on soft, boggy soil. With regard to

PLANTING, it is of the utmost importance to have the ground thoroughly prepared by trenching, draining, and breaking up the subsoil, especially in cases where there is what is termed a hard pan, and as a general rule, not only in the case of this tree, but also that of others, care should be taken to plant each particular species on soil suitable to its healthy development. All newly planted conifers ought to be provided with proper shelter, especially such as are liable to be cut down by late spring frosts, and in planting specimen trees in exposed situations I have found them to be greatly benefited by sticking a few Spruce branches into the ground around the young plants. In cases, too, where the trees are a few feet in height, it is a capital plan to plant four upright posts at equal distances from each other, and about 4 feet from the stem, and by nailing on these horizontal rails and weaving a few Spruce branches through them, an excellent shelter is provided at small cost. When the young trees are fairly established the posts and rails should then be moved. The cold, cutting, frosty winds which we frequently experience in March, April, and even in May, are often very destruc-

tive to newly-planted conifers, and, as far as my experience goes, too high a value cannot be attached to that most important condition—shelter. J. B. WEBSTER.

EDWARDSIA GRANDIFLORA.

IN reference to this fine flowering shrub, of which we gave an illustration in THE GARDEN last week (p. 441), Mr. Scrase-Dickins writes as follows "About five years ago our gardener had some seeds sent him from New Zealand, which have turned out to be those of *Edwardsia grandiflora*. From these seeds a number of plants were raised, and were planted out in the borders before we knew their name, but they have died from the cold, or more probably the damp of our English climate. A couple, however, were kept in pots in a cold greenhouse, which, owing to the hot-water pipes having gone wrong, was heated only by a small petroleum lamp. They are now about 6 feet high, and one which had shed its leaves flowered beautifully last month; the other, which had retained them, had no bloom on it at all. This would seem to show that they do not like shade or damp, but should be well hardened in autumn, and will repay one for some slight protection in winter. The flowers, which are a greenish yellow when first they open, turn to a shade as nearly approaching golden as I know of in any flower (Daffodils not even excepted), and hang in thick clusters from all the side twigs. Next year I intend to try if they will force well, as they would make a pleasing variety in the early part of the year. One more point I may mention in their favour, namely, that the foliage is useful for cutting, lasts well, and is delicate and graceful for indoor decoration."

Berberis japonica.—A large breadth of this, quite an acre in extent, has for years formed cover near here for rabbits and hares, and not the slightest evidence of injury by eating it has ever been manifested. Being low growing, dense, and exceedingly hardy, this *Berberis* seems peculiarly adapted for forming cover, and the fruit produced every year in great quantities forms most acceptable food for myriads of song birds.—A. D.

Pyrus Malus floribunda.—This plant seems to increase in popularity every year, a fact which is easily accounted for, as when in flower it is so attractive as to be the admiration of everybody. It is almost pendulous in habit, and when on its own roots or grafted close to the ground it forms a spreading shrub eminently fitted for gardens of limited extent, as it may be easily kept in bounds without in any way destroying its natural character. Isolated specimens of it look well on Grass. Its blossoms, which are produced in the greatest profusion, are bright crimson in the bud state, and when open a pleasing shade of pink. It is frequently grafted standard high, and so treated is very satisfactory, as the long, slender branches droop in a very graceful manner. It is a native of Japan, and was introduced some years ago, but it is only since a coloured plate of it appeared in THE GARDEN that it has become so universally popular.—ALPHA.

Berberis Darwini and stenophylla.—Anyone seeing these *Berberis* in flower cannot fail to be struck with their beauty. Of the two, *B. Darwini* is perhaps the more striking, on account of its greater warmth of colour: its blossoms are deep orange, while those of *B. stenophylla* are more yellow, but the habit of this latter kind is better than that of *B. Darwini*. It has gracefully drooping branches, which render it very suitable for planting on rockwork or in other elevated positions in which it is seen to advantage. *B. Darwini* is not at all unsuitable for the same purpose; but where I think this variety looks best is in front of other low growing shrubs, from which it should be allowed to stand out clear and free, not crowded. As both of these *Berberis* are so floriferous and so beautiful, the wonder is that they are not grown in pots for the early embellishment of greenhouses or as window ornaments, as they may be kept to quite a small size by pinch-

ing them at the roots. The way to propagate these Berberises is by means of layers, the branches lending themselves readily to this mode of increase, especially those of *B. stenophylla*, which trail along the ground and only require just burying to get them to root. Both kinds also seed freely and admit of being raised in quantity in that way. Sow when the berries are ripe in sharp sandy soil, and when the young plants are large enough single them out and transplant. The proper time to do this is in April, a season when I have always found these and other evergreen Berberises to move best, as when caught just before the buds burst, they start off at once and soon get fresh hold of the soil.—S. D.

EXHIBITIONS.

CRYSTAL PALACE.

MAY 19.

THE annual summer show, held at the Crystal Palace on Saturday last, was remarkable both for its extent and the high quality of the exhibits—the most successful show, indeed, that has taken place there of late years. The central transept was gay with colour, and long lines of crowded stages stretched throughout the north and south wings, the whole forming an extremely bright display. The schedule comprised twenty-six classes, each being represented in most cases by high class exhibits, many of which, such as stove and greenhouse plants, Clematises, Azaleas, and others, were, as a matter of course, the same as those shown in the Regent's Park on the 16th inst.

ORCHIDS were exceptionally well shown, better than had been seen here for some seasons, and were also more numerous on account of prizes consisting of about £20 being offered for groups of Orchids of not fewer than forty plants. Though there were but two groups shown, these made a most attractive display, and, judging by the crowds that surrounded them, they were highly appreciated. The best group came from Mr. Southgate's garden, Selborne, Streatham, and was indeed a choice and interesting gathering, and we imagine that Mr. Salter, the gardener, exceeded the stated number of forty, for the group occupied a considerable area. It was a thoroughly representative collection, including all sections of Orchids, but the finest were the cool house kinds and Cattleyas. Among the most noteworthy of the group were *Masdevallia Chimæra* and *bella*, both with numerous flowers and buds, M. Shuttleworthi and *Harryana*, *Cattleya Mendelli*, C. Mossie, the rare *Cypripedium Druryi*, and the new hybrid C. *albo-purpureum* in the way of C. *Dominii*, but with the flowers of a rosy hue. Among the *Dendrobiums* was a small, but copiously flowered plant of D. *Falconeri*, one of the most beautiful of all, likewise the rare D. *Brymerianum* with large yellow flowers having a long fringe to the labellum. D. *albo-sanguineum*, also rather uncommon, was among the *Dendrobes* and fine plants of commoner species, such as *Devonianum*, *nobile*, *primulinum*, together with the splendid new hybrid, D. *Ainsworthi*. The true *Odontoglossum nævium majus*, a choice and uncommon variety, was well shown, also such lovely species as O. *Ruckerianum*, *Andersonianum*, and numerous forms of O. *crispum*. Some fine spikes of *Odocidium Marshallianum* bearing crowds of large bright yellow blossoms lit up the group here and there, and another bright yellow species, O. *concolor*, both grown admirably by Mr. Salter, was a great attraction. These are a few of the most remarkable in this choice collection, which well deserved the prize awarded it. The other group, from Mr. H. James, was likewise a fine one, and contained numerous choice and rare things, such as *Odontoglossum Chestertoni* and *Wilckeanum*, *Lælia Schilleriana*, *Burlingtonia fragrans* (with half-a-dozen spikes, some splendid forms of *Cattleya Mendelli* and *Mossie*, *Thunia alba*, and others. There were four collections of nine Orchids from amateurs, the best being from Mr. Cobb's garden in the neighbourhood, and his garden showed a very creditable collection, consisting for

the most part of admirably grown specimens. The finest was a grand plant of *Odontoglossum vexillarium*, a richly coloured variety bearing over a dozen spikes. There were also *Dendrobium thyrsiflorum*, with twenty spikes; *Masdevallia Harryana*, a good plant with a dozen blooms; the white *Vanda Denisoniana*, with two spikes; *Cattleya Mossie*, with eight flowers; *Cymbidium Lowianum*, with two spikes; *Vanda suavis*; and *Oncidium phymatocilium*. The second collection, from Mr. Child, Garbrand Hall, Ewell, was remarkable for a wonderfully fine plant of *Vanda suavis*, bearing eight large spikes of bloom. Other good plants were *Dendrobium Farmeri* and *Masdevallia ignea aurantiaca*, a variety with flowers of a decided orange-yellow colour. The third collection, from Mr. Salter, contained a grand plant of *Dendrobium nobile*, also of D. *Wardianum* and an uncommonly fine form of *Cattleya Mossie* named *Southgatei*, which is remarkable for the rich colour, large size of bloom, and broad lip. The two collections from nurserymen contained a few good specimens. The first group, from Mr. H. James, included a grand plant of *Cypripedium Stonei*, with three spikes, also good varieties of *Masdevallia Harryana* and *Veitchi*. A fair specimen of *Dendrobium densiflorum* was in Messrs. Jackson's group.

THE AZALEAS, from which the show derived its brightest features, were as usual prodigious pyramids of brilliant and varied colouring. There were five classes set apart for them, and these being all more or less numerously represented, there was an extensive display. Mr. Turner, as usual, was the most successful in the nurserymen's classes, and his plants were even better than at the Regent's Park a few days previous. His collection of eighteen small plants was particularly noteworthy, as they evinced such skilful culture and the varieties were newer. We noted such beautiful kinds as *Madame Van Houtte*, *Jean Vervaene*, *Grandis*, *Belle Gantoise*, *Madeleine* (a lovely new double white), *Princess Clotilde*, all of which will in time no doubt supplant the old sorts now shown in large specimens. Those two well-known Azalea exhibitors, Mr. Child and Mr. Ratty, were again in rivalry; both showed admirably, having ponderous densely flowered plants, which in no small measure added to the brightness of the show. The collections from Messrs. Reed and Messrs. Jackson were quite up to their usual high standard of excellence.

FINE FOLIAGED PLANTS were unusually fine, particularly those from the Rev. Canon Bridge's garden at Beddington, whose gardener, Mr. Penfold, is evidently a skilful cultivator of this class of plants, and, moreover, grows and shows some that are out of the ordinary run of exhibition plants. On this occasion in his collection of nine, the finest shown, he had a grand specimen 5 feet high by 4 feet through of an *Asparagus* named *plumosus*, but was probably tenuissimus. This was a mass of feathery foliage of a delightful emerald green. The other plants in this group were *Alocasia macrothiza variegata*, a huge specimen; *Carludovica Drudei*, a new *Cyclanth*, like a Fan Palm and a very handsome-leaved plant; *Davidsonia pruriens*, a noble plant with large pinnate leaves, the young ones being of a reddish hue; *Dieffenbachia Bausei*, a huge plant, the finest we have ever seen of this, one of the finest of all the *Dieffenbachias*, though one of the oldest; *Croton interruptus*, large and well coloured; *Phormium tenax Veitchi*, *Spathiphyllum pictum*, an Aroid with enormous leaves of a deep green blotch with a lighter hue, and extremely ornamental; and *Dracæna Lindenii*, one of the finest ornamental-leaved plants now grown, being noble, yet elegant in growth and bright in colour, the leaves being green banded with golden yellow. Mr. Penfold was also the leading exhibitor of a collection of nine Ferns, remarkable alike for high cultivation and novelty. It contained *Adiantum gracillimum*, a perfect specimen of this light and elegant Maiden-hair Fern; a huge spreading plant of *Davallia polyantha*, the young fronds of which are of a coppery red tint, thus contrasting well with the colour of the older fronds; *Alsophila Rebecca*, a newly introduced species, and one

which promises to be a valuable ornamental plant; a tall *Dicksonia antarctica*, the well-known *Onychium japonicum*, a fine plant; *Cyathea Smithi*, *Davallia fijiensis*, a beautiful Hare's-foot Fern; a grand specimen of *Adiantum Sanctæ-Catharinæ* and *pellucida*, one of the large growing Filmy Ferns. In Mr. Peed's group were fine plants of *Adiantum farleyense* and *formosum*, *Pteris argyrea*, and *Gymnogramma chrysophylla*. *Crotons* were few, but shown admirably by Mr. Cranston's gardener, Mr. Bird, who had fine specimens of *Disraeli*, *Queen Victoria*, *Evansianus volutus*, *Andreanum*, *pictus*, *Sunset*, *interruptus* and *undulatus*, a capital selection as fine as could be made not only for exhibition, but for general cultivation. Mr. Bird also showed the best nine *Dracænas*, rather small perhaps, but well grown and the foliage highly coloured. Among the most conspicuous sorts were *Tillingi*, *Anerleyensis*, *Thomsoni*, and *Gladstonei*, all excellent sorts. In the other collections we noticed *Cooperi*, as finely coloured as we have ever seen—better, in fact, than all the newer sorts shown. Those named *Baptisti*, *Fraseri*, *ferrea grandis*, *amabilis*, Mrs. *Freaker*, we thought the best amongst the others. We noticed that some of the exhibitors of *Dracænas*, seemingly not content with the natural gloss on their leaves, had rubbed them with oil, which on some plants was so thick as to be ready to drop off. Such practices as this ought to be discouraged.

STOVE AND GREENHOUSE PLANTS were numerous, but the chief collections, those from Mr. Chapman, Messrs. Jackson, and Mr. Tudgey, were much the same as those exhibited at Regent's Park and reported on last week. In the various collections there were some very fine specimens of the Banner flower (*Anthurium Scherzerianum*), one in Mr. Tudgey's group being at least 5 feet through, and bearing several dozens of brilliant scarlet spikes. We were glad to see that the practice of enveloping the flower-stems of this plant in white cotton wool, under the impression probably that it showed the colour of the spathe off to better advantage, has been all but discontinued. Last year several exhibitors followed the practice, but this season there was but one, and we hope that the judges' protest against it will not be disregarded. A wonderfully fine specimen of this *Anthurium* was shown by Mr. Churchfield. It was perfection as regards health, and carried several dozen of its large broad spathe, almost as fine as those of Ward's variety. It was deservedly awarded an extra prize. The *Heaths* from Messrs. Jackson's nursery, Kingston, were, as usual, shown in excellent condition. A plant in the collection of nine of *E. ventricosa magnifica* was a model of a perfect specimen plant, being a yard or more through and a mass of bloom. The *Clematises* from Messrs. Jackman's nursery at Woking were here, as at Regent's Park, the centre of attraction; they occupied a sloping bank at the end of the central transept, and the soft, mellow hues of their huge flowers formed, as it were, a kind of relief to the gayer colours of the Azaleas by which they were surrounded. The *Pelargoniums*, too, from the Slough Nurseries were a great attraction, being all fine specimens, profusely flowered, and representing the best sorts in their respective sections. Some *Roses*, likewise from Mr. Turner, were charming specimens, and though small skilfully grown. *Gloxinias* were poor, but *Calceolarias* were exceptionally fine, and more numerous than usual. The best dozen were shown by Messrs. Carter, High Holborn. A large group in the central transept, awarded an extra prize, was also exhibited by Messrs. Carter, whose strain—an excellent one—is characterised by bright and varied colour and large punched flowers abundantly produced on vigorous habited plants. Mr. Salter had a second group of a dozen, and he also exhibited an extensive collection, for which he was awarded an extra prize. *Tuberous Begonias* were poorly shown in the competing classes; the plants were large, but not well flowered.

MISCELLANEOUS EXHIBITS included a large and admirably arranged group of plants on an area of 200 square feet, from Messrs. Laing's nursery, Forest Hill. It consisted of tall spreading

Palms, Dracænas, and other fine foliaged plants in the background, while in front were Azaleas, Begonias, Gloxinias, and other gay flowers interspersed with elegant foliage. This group was awarded a prize of £10, and occupied a conspicuous position in front of the orchestra. The same exhibitors also contributed a collection of new tuberous Begonias, Caladiums, and cut blooms of Niphetos Rose. An extra prize was awarded to Mr. Bird for a very fine group of Mignonette plants large and profusely flowered and trained in various ways. Messrs. Dobson, Isleworth, also received an extra prize for a group of Calceolarias, and Mr. Hooper, Bath, for Pansies and other flowers.

FIRST-CLASS CERTIFICATES were awarded to Messrs. Laing, Stanstead Park, for tuberous Begonias Black Douglas (single), Mrs. Morgan (single), Canary Bird (double), Prince of Wales (double), and Queen of Scots (double), also for Caladium cardinale, ornatum, and Verdi. To Mr. Turner, Slough, for Azalea Madame Van Houtte, Rose Merveille de Lyon, and Pelargonium Dresden China. To Messrs. Jackson, Kingston, for Impatiens Sultan.

ROYAL HORTICULTURAL.

MAY 22 AND 23.

NOTWITHSTANDING the chequered fortunes of this Society, its great annual summer show, held on Tuesday and Wednesday last, compares favourably with its predecessors. It was, however, evident that the Society is in as straightened circumstances with regard to space for holding its shows as it has long been in financial matters, the Fisheries Exhibition having taken up nearly the whole of the South Kensington Gardens, leaving but a corner for the Society's use; consequently habitual frequenters of the flower shows here were deprived of their customary open-air promenade, for the small space outside the tent was wholly taken up by the implement exhibition, which, as usual, was an interesting one, though not so large as hitherto. The flower show was, as on former occasions, held under canvas, the great tent being supplemented by a smaller one placed at right angles to it, in which the fruit, vegetables, cut flowers, and miscellaneous exhibits were shown. The principal tent was well filled and looked as bright and cheerful as ever we have seen it, Mr. Barron having balanced the foliage and gay colours of the different plants admirably. Every part of it was interesting, and there was a conspicuous absence of vacant space, so obtrusive on other occasions. Some three dozen classes were comprised in the schedule, nearly every one of which was represented, and besides there were numbers of non-competitive exhibits, though noted exhibitors, such as Messrs. Veitch, Bull, and others, among nurserymen, and Sir Trevor Lawrence, Canon Bridges, and Mr. Whitbourne, among amateurs, were conspicuous by their absence, doubtless attributable to the show being open for two days.

ORCHIDS.—Everyone seemed somewhat disappointed in not seeing a better competition among exhibitors, considering that upwards of £50 in seven prizes were offered. There was no really first-rate collection represented in the competition, although there were some creditable plants. There were four collections of ten plants from amateurs, the best being that from Mr. Southgate's garden, Streatham (gardener, Mr. Salter). This consisted of good specimens of *Cypripedium Domini*, *Dendrobium nobile* (admirably flowered), *D. Wardianum*, *Cattleya Southgatei* (a splendid form of *C. Mossiae*), *Cypripedium Lawrencianum*, *Odontoglossum vexillarium*, *O. citrosum* roseum, *Cattleya Warneri*, and *C. Mendelli*. The second collection, from Mr. Child, Garbrand Hall, contained a grand example of *Vanda suavis* with six spikes on two breaks, *Dendrobium nobile*, a very fine form of *Cypripedium Hookeri*, an uncommonly fine pot of the hardy *C. pubescens*, also *C. barbatum* and *Masdevallia ignea aurantiaca*; but several of the plants were made up, though on the whole this collection contained several finer plants

than those in the first group. Mr. Little, of Uxbridge, who has just commenced Orchid culture, showed a collection of small, but fresh and well-grown, plants, among which were *Zygopetalum Gautieri* on a Tree Fern, just developing fronds, a few good *Cattleyas* and *Dendrobies*. There were two groups of Orchids of not less than forty plants, one from Mr. James, who was first, the other from Messrs. Jackson. In the best group some splendid varieties of *Cattleya Mossiae* and *Mendelli* were noteworthy, also of *Odontoglossum crispum*, *Cypripedium Stonei*, a grand plant with five spikes; *Cattleya Schilleriana*, *Aerides Fieldingi*, *Masdevallia Harryana*, and others a variety of the new and rare *Odontoglossum cordatum aureum*. Messrs. Jackson's group contained numerous well-grown plants, but not many new or rare kinds. The competition for the prize of £10 offered by Sir Trevor Lawrence, Bart., for the best collection of twelve *bona-fide* plants was limited to two competitors—Mr. Child, who was first, and Mr. James. In the first group were *Vanda suavis*, a grand specimen with nine flower-spikes on two breaks; *Aerides Fieldingi floribunda*, also a very fine specimen with six spikes most of them with several branches, but the flowers were not fully expanded; *Saccolabium retusum* with four long and fine spikes; and *Dendrobium Farmeri* with eight spikes. The other plants were not remarkable, the kinds being *Anguloa Clowesi*, *Odontoglossum crispum*, *Cypripedium barbatum*, *Calanthe veratrifolia*, *Cattleya Mossiae*, and *Saccolabium ampullaceum*. Mr. James' twelve included *Odontoglossum vexillarium*, with four spikes; *Cattleya Mossiae*, a fine variety; *C. Mendelli*, *Aerides Fieldingi*, *Odontoglossum crispum*, *Cypripedium Lawrencianum*, *O. gloriosum*, but none were very remarkable as specimen plants. The greatest attraction on the Orchid bank appeared to be an extensive collection of Orchids from Mr. Peacock's noted collection in his garden at Sudbury House, Hammersmith, which, indeed, formed a very pretty group, admirably arranged on a jutting slope, with light and graceful Palms and Ferns, which blended harmoniously with the gorgeous hues of the Orchids. The collection could not have numbered less than a hundred plants, though we imagine that even this number was scarcely missed from Mr. Peacock's collection, judging by what we saw a few days previous to the show. It was a thoroughly representative display and admirably showed the wealth of Orchids in May. There were no fewer than twenty species of *Odontoglossum*, viz., *Alexandrae* (numerous varieties), *Andersonianum*, *Cervantesi*, *citrosum*, *cordatum*, *cordatum superbum*, *Coradinei*, *gloriosum*, *hebraicum*, *Halli*, *maculatum*, *nebulosum*, *Pescatorei*, *Phalanopsis*, *polyanthum*, *Roelzii*, *Rossi*, *triumphans*, *tripudians*, *vexillarium*. Of *Dendrobies* the most conspicuous were *chrysotoxum*, *Picardi*, *suavissimum*, *tortile roseum*. Then there were some splendid forms of *Cattleya Mossiae* and *Mendelli*, and some superbly flowered examples of the yellow *C. citrina*, which is grown uncommonly well by Mr. Vicary. Other noteworthy Orchids in the display were *Brassia verrucosa*, *Burlingtonia venusta*, *Cypripedium niveum*, *C. levigatum*, *Oncidium ampliatum*, *O. Krameri*, *O. Marshallianum*, *O. cucullatum*, *O. phymatochilum*, *Phajus Wallichii*, *Epidendrum vitellinum majus*, *Lælia purpurata majalis*, *Lycaste Skinneri* in variety, *L. aromatica* and *cruenta*, *Masdevallia Harryana*, *M. Houtteana* (with a score of flowers), *Nanodes Medusæ*. A silver gilt medal was an appropriate award to Mr. Peacock's gardener (Mr. Vicary) for this admirable display.

STOVE AND GREENHOUSE PLANTS were quite up to the average standard in quality, but the collections were somewhat fewer than usual in number. Among nurserymen, Messrs. Jackson's plants were in their best form, the dozen they showed being as fine as could possibly be desired, all being symmetrical in size and shape, not faced, i.e., fan trained, so as to bring all the flowers on one side, but perfect specimens profusely flowered, and they looked as fresh as if they had not before done duty at an exhibition this season. As the collection was exceptionally fine, we append the names of the plants: *Hedera fuchsoides*, *H. Tu-*

lipifera, both models of skilful culture; *Dracophyllum gracile*, *Aphelexis macrantha purpurea* and *rosea*, *Erica affinis* and *E. Webbiana*, all marvellous examples of plants difficult to manage. The remainder consisted of easier growing subjects, such as *Azalea Souvenir de Prince Albert*, *Clerodendron Balfouri*, and *Anthurium Scherzerianum*, the latter well grown and flowered. In Mr. Tudgey's second best group were some fine yellow *Ericas* and a few good *Azaleas*, which latter formed also the chief feature of Messrs. Peed's collection. Amateurs' collections were four in number, and, as usual, Mr. Spode's gardener, Mr. Chapman, from Rugeley, in Staffordshire, outstripped the suburban competitors by a long way. The eight which he showed seemed to be the pick of the plants in the larger collections shown by him at other London exhibitions during the last fortnight, but which looked scarcely the worse for their transportation and consequent knocking about. They comprised a monster *Erica Cavendishi* and *E. depressa major*, both the perfection of bloom and vigour; *Ixora Williamsi* and *I. coccinea*, *Acrophyllyum venosum*, *Dracophyllum gracile*, and *Anthurium Scherzerianum*, the latter a wonderfully fine specimen of a large bright spathed variety—so fine, indeed, that the judges selected it as the best stove or greenhouse plant in the whole exhibition, worthy of receiving the Veitch memorial prize and medal. It bore a large sheaf of spathes, and the broad, vigorous foliage indicated skilful culture. Other amateur collections exhibited were from Mr. Bell's garden, Garbrand Hall, Ewell, which was second, and in which there were some huge and well-flowered *Azaleas*; Mr. Rann, gardener to Mr. Warren, had a few good specimens in his group, and among the plants from Mr. P. Crowley's garden at Waddon House, Croydon, was an uncommonly fine specimen of *Cypripedium villosum*, some 3 feet across, and carrying nearly half a hundred fine blooms—as fine an example of this Lady's Slipper as we have ever seen.

ROSES were shown from the Cheshunt and Slough Nurseries as usual in splendid condition, but perhaps not quite equal in quality to those shown here during the last and previous years. Messrs. Paul were the only exhibitors of nine plants—a fine collection placed on one of the principal slopes in the tent where they could be seen to advantage. Among them was a splendid Charles Lawson large and fresh and covered with superb blooms. There were also grand plants of Cheshunt Hybrid, a fine pot Rose for exhibition; *La France*, *Juno*, *Beauty of Waltham*, *Edouard Morren*, *Juno*, *Dr. Andry*, *Centifolia rosea*, *Céline Forestier*, and *Perfection de Monplaisir*, all established favourites. Surrounding this group was the collection of twenty Roses in 10-inch pots, which was also first—excellent specimens large for the size of pot in which they were growing, and profusely furnished with very fine blooms. It comprised nearly all the sorts enumerated above in addition to such fine ones as *Edouard Andre*, *Alba rosea*, *Catherine Soupert*, *Duke of Edinburgh*, *Jules Finger*, *Camille Bernardin*, *Royal Standard*, and *Madame Lacharme*. Besides these, Messrs. Paul showed a pretty group of standard and bush plants of the new *Paquerette* Rose, covered with numbers of its neat little, double white blossoms in clusters similar to others of the *Rosa polyantha* type. On the opposite slope was Messrs. Turner's collection of twenty Roses, which were but little inferior to those from Cheshunt, but they were not of uniformly large size and good quality. There were beautiful specimens of such favourites as *Paul Neyron*, *Duchesse de Vallombrosa*, *Souvenir d'un Ami*, *Duke of Edinburgh*, *Mdme. Victor Verdier*, *Edouard Morren*, *Camille Bernardin*, *Sir Garnet Wolseley*, *Caroline Kuster*, *E. Y. Teas*, and *Marie Baumann*, all of which are admirably adapted for pot culture and flowering early. The cut blooms of Roses from Messrs. W. Paul and Sons' nursery, Waltham Cross, were a great attraction, the blooms being remarkably fine and numerous, there being about a dozen boxes containing some two dozen trusses each. We noted among them the new *Queen of Queens* in fine condition; also the new *Merveille*

de Lyon, which seems handsomer every time we see it. There were also fine examples of such superb varieties as Lady Sheffield, Masterpiece, Baroness Rothschild (a whole boxful of splendid blooms), La France, and Paul Neyron. Three new Hybrid Perpetuals in pots were also shown by Messrs. Paul, named Miss Edith Gifford, Gilbert, Marguerite de St. Romer. For these and the cut blooms the exhibitors were awarded a silver medal.

AZALEAS.—The show of these was for the most part a repetition of that at the Crystal Palace and Regent's Park the week previous. Mr. Turner, of Slough, was the first, as usual, among nurserymen, and he also showed a numerous collection not for competition. Mr. Child's collection in the amateurs' class had no rival, but was well deserving of the first prize, his plants being huge, densely-flowered specimens. There were but two exhibitors of twelve Pelargoniums (half show and half fancy varieties), and those two well-known exponents of these flowers, Messrs. Turner and Little, were again in rivalry, winning the first and second prizes in the order named. The Slough collection were all large and profusely flowered, and included the sorts Prince Leopold, Claribel, Illuminator, Viscount, Maid of Honour, and Evelyn among the show type, and of fancies Roi des Fautaises, Mrs. Porter, Fanny Gair, Princess Teck, East Lynn, and Helen Beck. Mr. Little's plants were a little inferior in merit, and the selection somewhat varied from the other. Among the show kinds were Snowflake, Sultana, Isabel, Prince Leopold, Miss Bradshaw; and of fancies Mrs. Goddard, Polar Star, Princess Teck, and Lucy. Tuberous Begonias were well shown from the Stanstead Nursery, Forest Hill, the head-quarters of these beautiful greenhouse plants. In their group of fifteen Messrs. Laing had some excellent varieties, such as Lothair, Hettie, Mrs. J. Freeman, Novelty, Eclipse, Prince of Orange, Madame Laing, Hon. Mrs. Brassey, Ball of Fire, Mad. Stella, all single sorts, with colours of various shades—crimson, cerise, scarlet. Among whites and light sorts were Snowflake and Delight, both first-rate whites; Golden Gem, one of the finest yellows; and Sulphur Queen, not sulphur, but an undecided white. Messrs. Jackman, of Woking, had no rival competitor in the class for nine Clematises, which were as fine as those previously shown by this firm in London this season. The varieties were Alba Magna, William Kennett, an extremely fine purple variety; Excelsior, Fairy Queen (one of the finest light sorts), Impératrice Eugénie, Lanuginosa candida, Duchess of Edinburgh, and Picturata, all splendid sorts. The plants were, as usual, large and balloon-shaped, and they formed a group in a prominent position facing the entrance to the large tent. Mr. Noble, Sunningdale Nursery, took a silver Banksian medal for a group of Clematises, smaller plants than those from Woking, but representing very fine and distinct sorts.

FINE FOLIAGED PLANTS were shown admirably by three or four exhibitors. The eight from Handcross Park, which occupied a prominent position in the central part of the tent, formed a noble group. It contained huge specimens of *Areca sapida*, *Cycas revoluta*, *Pandanus Veitchii*, *Latania borbonica*, *Gleichenia Mendeli*, and three large and handsome coloured Crotons, named Queen Victoria, Challenger, and Albicans. The two other prize winning groups, from Mr. Crowley's garden and Mr. James' nursery, were both fine. The former contained a grand specimen of *Maranta Makoyana*, one of the finest examples we have ever seen of this plant; *Davallia Mooreana*, a huge spreading plant; *Diefenbachia Bausei*, a grand specimen; *Croton Wiesmanni* and *Youngi*, and *Microlepia hirta cristata*. In Mr. James' group were a fine example of the rare *Macrozamia Denisoni*, a monster specimen of *Pandanus Veitchii*, *Stevensonia grandifolia*, *Theophrasta imperialis*, *Cycas revoluta*, *Areca lutescens*, and *Scaevola elegans*, the whole forming a fine group.

FERNS have rarely been shown in such grand condition as they were on this occasion, particularly the two collections in the amateurs' class which came from Handcross Park and Garbrand

Hall. Both were excellent, and that placed second was but little inferior to the first, though there was no doubt about the justness of the award. That shown by Mr. Rann for the first prize included three grand *Gleichenias* of large size and in vigorous health, furnished with young fronds just developed. The species were *G. rupestris Mendeli* and *rupestris gigantea*. The other plants were *Cyathea Burkei*, with a huge drooping head of fronds on a tall stout stem; a noble plant of *Dicksonia antarctica*, and a large *Davallia Mooreana*, some 8 feet or 9 feet through. Mr. Child's plants were *Microlepia hirta cristata*, a grand plant some 7 feet across; *Davallia Mooreana*, about the same size; *Dicksonia squarrosa*, *Gleichenia semivestita*, and the finest plant of *Phlebodium aureum* we have ever seen, it being some 5 feet or 6 feet through, and a complete mass of long robust fronds, which being of a silvery grey tint formed a charming contrast to the foliage of the others. When grown in such a way this is a very beautiful Fern. *Gleichenia dicarpa* was the poorest specimen in the group, and that even was a fairly good plant.

HARDY PLANTS were not remarkable, there being but one collection of thirty plants from Messrs. Hooper. These, though comprising a good selection and well grown, were not sufficiently forward in bloom, and so were only awarded the second prize. The same firm showed the only collection of cut hardy flowers which contained a few attractive and choice things. Tulips and *Ixias* also came finely from Messrs. Hooper. There were several exhibitors of five dozen blooms of Pansies, the best being those brought all the way from Edinburgh by Messrs. R. B. Laird & Sons, the nurserymen there, and which of course were very fine, as Scotch Pansies usually are. From the west country, Messrs. Meddick and Catley, both of Bath, showed some fine productions.

GROUPS OF PLANTS.—Those in competition for the prizes were three in number, Messrs. Fromow, Hooper, and Cutbush, who were placed in the order named. As usual, the awards of the judges gave rise to some comment. It seems always a bone of contention as to what constitutes artistic grouping of plants. None of the groups were very remarkable. The first group was made up of the usual run of fine foliaged plants, interspersed with flowering plants and notably tall spires of white Lily, which added to the appearance of the group. A pretty fringe hiding all the pots was a merit in this group. The second group was not bright enough, though it contained some excellent specimen fine foliaged and other plants. An ugly row of pots and pans marred the edge of this group. Messrs. Cutbush's group, had it not been so crowded, would have been the best of the three, for it contained some excellent plants, chiefly well-flowered, hard-wooded subjects, and these were arranged in masses, which had a better effect the mixed style. There was enough material to make three groups of the same size. An extensive and miscellaneous group was exhibited by Mr. B. S. Williams, which, as usual, included numerous fine Orchids. A silver-gilt medal was awarded. Messrs. Laing, Forest Hill, likewise filled one of the spacious central banks in the large tent with a fine mixed collection, and were also awarded a silver medal. These two groups contributed in no small degree to the attractiveness and interest of the show. Numerous other miscellaneous collections were shown, notably new *Dracenas* and a fine collection of *Calceolarias* from Messrs. Carter, a fine group of Crotons from Mr. Causton's garden, Dulwich, cut flowers of hardy plants from Messrs. Barr and Son, hardy Azaleas from Mr. Waterer, Knap Hill, Mr. Turner new Azaleas, Messrs. Hooper Tulips, and other cut flowers.

Fruit.—A large show of fruit at such an early date was hardly to be expected, but, nevertheless, there was a creditable display, and, taken on the whole, the quality was excellent, and showed well what the skill of the English gardener can do as regards the production of early forced fruits. There were seven competitors in the class for one Pine-apple, the best, from Mr. Roll's gardener (Mr.

Coomber), being a handsome and heavy Smooth Cayenne. Other good fruits of the same variety, and also of the Queen, were shown by the other exhibitors. Six exhibitors competed for the three prizes offered for three bunches of Black Hamburg Grapes. The finest were from Mr. Barnes's gardener (Mr. Loudon), The Quinta, Chirk, who has been so successful the last few years in exhibiting Grapes. His three bunches were remarkable for large size of bunch and berry, considering the early date, and good colour, though in this respect they were not equal to those shown for the second prize by Mr. Austen, from Sir G. Smythe's garden at Ashton Court, Bristol. Mr. Fyfe, gardener to Mr. Dick, Thames Ditton, was the other successful exhibitor, his produce being of very good quality. There were but three sets of three bunches of any black sort of Grapes. Mr. Mowbray, the Earl of Leven and Melville's gardener, showed for the first prize some handsome and well-finished bunches of Black Prince, and the same variety also secured the second prize for Mr. Edwards, Fowley, Liphook. Some uncommonly good bunches of Alnwick Seedling were shown from the Marchioness of Camden's garden by Mr. Johnstone, which showed that this much criticised sort may be produced in fine condition in the middle of May. There was no entry for Muscats of Alexandria, and the class for any other variety of white Grapes was not well represented. Mr. Austen was first with some creditable bunches of Foster's Seedling, and the same sort won the second prize for Mr. Miles, and Buckland Sweet-water was shown for the third prize by Mr. Johnstone. Mr. Loudon had some good bunches of Golden Champion, which, however, were green, and it seemed a pity they should have been cut so early. Some good Peaches were shown among the seven dishes. Mr. Austen was first with some fine and highly-coloured fruits of Hale's Early, which is evidently a first-rate early variety. Sir J. Pease's garden contributed the second best dish, Mr. McIndoe having some large examples of Bellegarde, and Dr. Fuller's gardener (Mr. Nash) was third with a sort called Early Rivers, which were somewhat undersized. Other sorts shown were Stirling Castle, Princess Beatrice, Merlin, and Grosse Mignonne. Four exhibitors contributed six fruits of Nectarine. Mr. Nash had some excellent fruits of Elruge for the first. Violette Hâtive was second, and Hunt's Tawny third. Black Circassian Cherries were shown in excellent condition by Mr. Miles for the first place, the other dish being from Mr. Hare, of the Elton variety, also good. There were but five dishes of Strawberries. A fine dish of President, from Mr. Goldsmith, Hollenden, Tonbridge, was first. Some excellent fruits of Sir Joseph Paxton, from Purley Park, Reading, was second, and Sir Charles Napier, Mr. Cunard's garden, Twickenham, third. Lord Braybrooke's gardener, Mr. Vert, showed an uncommonly fine dish of the La Grosse Sucrée variety in the non-competitive class. Melons, as usual, were numerous, there being fifteen fruits. A fine fruit of Hero of Lockinge was shown by Mr. Herrin, from Chalfont Park, Bucks. Sutton's Masterpiece, from Mr. Johnstone, was second, and Mr. Austen showed Carter's Blenheim Orange for the third prize. Among other sorts shown were Eastnor Castle, Hero of Bath, Best of All, Scarlet Premier, and Victory of Bath. The new sort Masterpiece was shown by several exhibitors. Among the five exhibitors of Tomatoes Mr. Miles was first with large and excellent fruits of Stamfordian; Dedham Favourite from Viscount Barrington's gardener (Mr. Meads) was second; and Mr. Austen had Hathaway's Excelsior, Trophy was also shown well.

Vegetables were uncommonly good, though there were but four collections of ten kinds. Mr. Austen, of Ashton Court, was first with a collection remarkable for its uniform excellence and good selection of sorts. It consisted of Leamington Broccoli, Early Nantes Carrot, Hathaway's Excelsior Tomato, Ne Plus Ultra Bean, Victory of Manchester Cucumber (a fine sort), William I. Pea, Veitch's Ashleaf Potato, Moore's Vegetable Cream Marrow, White Naples Onion, and a bundle of fine

Asparagus. A scarcely inferior collection from Mr. Miles, of Wycombe Abbey, was second; it consisted of Ledsham's Latest of All Broccoli (evidently a fine sort), Osborne's Forcing Bean, Fetch's Favourite Cucumber, Queen Onion, Stamfordian Tomato, Lady Paget Potato, Nantes Horn Carrot, and some fine Asparagus. The best of Mr. Ward's dishes were American Wonder Pea, President Garfield Tomato, Connover's Colossal Asparagus, Canadian Wonder Bean, Hammersmith Kidney Potato, Queen Onion, and Longford Castle Cabbage, the last evidently an excellent sort. Mr. Waterman, Aylesford, Kent, showed the other collection, which comprised a fine dish of Culverwell's Telegraph Pea, the best in the show; also of Hathaway's Excelsior Tomato, Canadian Wonder Bean, Early Border Potato, and others.

Veitch Memorial Prizes.—On this occasion the trustees of the Veitch Memorial Prize Fund offered a prize of £5 and the memorial medal for each of the undermentioned subjects: 1, best specimen stove or greenhouse plant in flower, to be selected by the judges from the plant classes, which was won by Mr. Chapman, with his grand plant of *Anthurium Scherzerianum*, before alluded to; 2, best specimen Orchid in flower, to be selected by the judges from the plant classes, won by Mr. Child for his plant of *Vanda suavis* with six spikes on two breaks, a grand specimen in perfect health; 3, best dish of three bunches of Grapes (one sort), to be selected by the judges from the fruit classes, taken by Mr. Loudon, for his three bunches of Black Hamburg, which took the first prize in the class for that Grape.

THE SPECIAL PRIZES offered by the following firms were competed for on this occasion: Messrs. Carter & Co. (five prizes), for one fruit each of their new Emerald and Blenheim Orange Melons; Messrs. Sutton (three prizes), for a brace of Cucumbers; and Messrs. Hooper (three prizes), for two dishes of early Peas, to include Laxton's Earliest of All. The best brace of Cucumbers was from Mr. Mortimer, of Purley Hall, Hero; Sutton's Improved Telegraph was second; and Tender and True third.

The Implement show.

In this department awards consisting of silver and bronze medals were made in the several sections into which the respective exhibits were divided, but owing to the fact that each exhibitor grouped his exhibits without regard to classes, comparisons for the purpose of making the awards were necessarily difficult. The implements and other objects were on this occasion very crowded, as the allotted space was so limited, but it is creditable to the various trade exhibitors that, in spite of the great counter attractions within the tents and buildings, they were enabled to make very respectable displays.

PLANT HOUSES, VINERIES, &c.—In this section Messrs. Foster & Pearson, Beeston, Notts, have a handsome span-roofed plant house of moderate dimensions, fitted with patent ventilating apparatus, and having on either side broad stages made of slate slabs resting upon cast iron supports; also, they have long span frames fitted with elevating ventilation and iron rod catches for holding the lights open with the most complete security. This plan is very simple and very effective, and is worthy of universal adoption. Messrs. W. Richardson & Co., Darlington, have a fine 40-feet half-span vinery fitted with full length narrow elevating ventilators—a modification of the Paxton system. This is a very fine house, well finished and arranged. They have also a capital assortment of plant frames. Mr. B. W. Warhurst has a three-quarter-span vinery, very neatly glazed, on narrow sash-bars without top putties, fully and effectively ventilated by means of automatic lifters. Messrs. Deards, of Harlow, have a short, but lofty, span house intended to show fully their Victoria dry glazing system by means of zinc duplicate clips and sliding caps that seem to be singularly effective in gripping the glass firmly without undue pressure on any one place. Messrs. W. E. Rendle & Co., Westminster, have a lean-to Peach house glazed on their patent "Acme" system now so popular

and well known. A great speciality of this house is that it is so fixed as to be easily removable at a tenant's will. Mr. G. Knowles, of Finsbury Pavement, has an odd-looking span plant house in which the upper portion of the sides or eaves project, so that more internal space is given to the heads of plants. Messrs. C. P. Kinnell and Co., Bankside, have a small span house suitable for amateurs erected to show their admirable horse-shoe boiler for the heating of small houses. The method of feeding the boiler by means of tip receiver is simple, and doubtless very effective. In the section devoted to movable plant pits and frames several of the same exhibitors enter examples. In addition to Messrs. Foster and Pearson mentioned. Messrs. Rendle and Co. have some admirable plant cases and handlights, as also have the Messrs. Deards; and the Messrs. Richardson have large movable plant frames and wall tree protectors. The latter firm and Messrs. Deards and Mr. Warhurst exhibit in the section for "Improved system of glazing, ventilation, &c.," but nothing specially novel seems to have been presented.

BOILERS.—Of these important adjuncts to any good garden there is legion, and in the section devoted to large ones for heating 500 feet of piping and upwards, perhaps the largest assortment comes from the Thames Bank Iron Company, who have an unmentionable variety of all sizes and sorts, including tubulars horizontal and erect, saddles, coil, conical, &c., and with their terminal saddle boiler take the silver medal in the class. Mr. B. Warhurst has a big display of huge boilers, inclusive of the Chatsworth, Paxton, Ben's, gold medal, cruciform, and many other designs, all evidently solid and enduring. Messrs. Deards have their queer looking Champion close coil boiler; Mr. Jenkins, Rotherham, shows a handsome assortment of independent designs and others for brick setting, all smartly finished off; and Messrs. Green & Co., Blackfriars Road, and Messrs. Richardson have tubulars and other specimens. The section for small boilers or modes of heating small houses brought some novelties, inclusive of the Messrs. Kinnell's boiler alluded to, and which obtained the silver medal. A very taking system is that seen in operation in the Messrs. Deards' span house, which consists of an open grate as fitted to a sitting-room, but the bars are hollow, and indeed a portion of a coil boiler from which the water flows into pipes that may be carried through the wall into an adjoining greenhouse. As seen in work, the arrangement was most simple, and the pipes were as hot as could be desired. The fire may be banked up at night and enclosed by means of a sheet iron guard. Messrs. Jenkins and Warhurst and the Thames Bank Co. also show in this section. Out of this section also came hot-water piping, valves, &c., the same exhibitors having samples of their manufactures in this department. A very interesting novelty was the new Reliance rotary valve of the Thames Bank Company, by which one valve only does the work usually allotted to three, and with such remarkable simplicity that we wonder the idea has not long before been adopted. A special certificate was awarded to this invention. The gold medal was awarded to this firm for the best general collection in the show.

LAWN MOWERS, ROLLERS, &c.—In the section for horse mowers Messrs. Thomas Green & Son are the only exhibitors, but do not compete for awards, neither do they in the much more fully represented class for hand mowers, though showing their excellent Silens Messor, Multum in Parvo, and other machines. Messrs. Deane & Co., King William Street, show good mowers in this section, and from Messrs. Follows & Bate, of Manchester, came in various sizes their capital Manchester Anglo-American and Climax machines, all so easy to work. The same may be said of the Pennsylvania mowers sent by Messrs. Lloyd, Lawrence, & Co., Worship Street, whose machines, like those just noticed, resemble the well-known Archimedean in fashion, though differing in essentials. All these machines work so easily that mowing is made a recreation rather than a labour. Satisfactory judgment as to relative usefulness, endurance, and good work can only be fairly

tested after a season's trial under precisely similar conditions, hence lawn mower trials so called are too often very misleading. Several firms send garden rollers, wheelbarrows, &c., but none call for special comment. Under this heading may well be included garden engines, pumps, syringes, which are numerous represented. Messrs. Warner & Sons, Cripplegate, exhibit very largely of these articles, and make a grand display, as also do Messrs. Deane & Co. and Mr. G. Knowles. With these also must be classed the patent irrigator apparatus on wheels, shown by Mr. J. Deverill, of Slough, so admirably suited where there is a constant supply of water to irrigate lawns, and indeed all kinds of plants and trees. The Simplex garden pump, shown by Messrs. Arnold & Sons, West Smithfield, is a very meritorious object, as also is the Pall Mall lawn edger and the spray distributor for the destruction of plant pests, shown by Mr. Wells, of Redhill.

GARDEN POTTERY is well represented in the stand of Mr. J. Matthews, Weston-super-Mare; and Messrs. Rosher & Co., Chelsea; the former has terra-cotta objects, vases, plant stands, statuary, &c., in the fashionable crushed strawberry colour, and the latter have mosaic objects of a similar nature in white stone and plaster. The latter firm also have a varied collection of edging tiles for garden paths.

WIREWORK, TENTS, &c.—In this division Messrs. J. J. Thomas & Co., Edgware Road, make a fine show of their varied work in wire in almost endless form and fashion, and all elegant and serviceable. Messrs. Green & Co. and Deane & Co. also show garden arches and other exhibits. The chief exhibitor of garden tents is Mr. B. Edgington, of London Bridge, whose examples are handsome and tempting, especially on sunny days. No garden where there is space should be without one of these delightful adjuncts. Mr. J. Unite, of the Edgware Road, is an exhibitor also of garden tents and of lawn tennis appliances. Mr. Lovegrove, of Slough, has a capital display of rustic garden furniture, summer houses, seats, tables, &c., all strong and useful. There are numerous other miscellaneous objects exhibited by the various firms named, and the result is if crowded at least a very interesting display.

Floral Committee.

On this occasion numerous plants were submitted to the committee, and first-class certificates were awarded to the following:—

CATTLEYA NOBILIOR.—A new species having affinity with *C. dolosa* and *C. Walkeriana*, but quite distinct from either. The pseudo-bulbs are from 4 inches to 6 inches long, an inch or so thick, cylindrical, and terminated by a pair of ovate leaves of thick leathery texture. The flowers measure some 5 inches across, with rather narrow sepals and petals of a lovely deep rose-pink colour; the broad labellum is also of the same colour, but conspicuously blotched with creamy white on the front lobe. It is a beautiful Orchid and a real addition to the genus. Exhibited by the Compagnie Continentale d'Horticulture, Ghent.

DENDROBIUM DEAREI.—A new species discovered a year or so ago by Colonel Deare, of Egham. It is one of the loveliest of the genus, and, moreover, distinct from any other species. The plant shown by Sir Trevor Lawrence was an exceptionally fine one, having stout pseudo-bulbs a yard or more high, clothed on the upper part with short, thick leaves densely arranged. This leafy stem bore four or five flower-spikes, each carrying from five to ten blooms, about 2 inches across, of snowy whiteness, save a blotch of delicate green on the labellum, which tends to emphasise the purity of the white. It seems to be a remarkably floriferous plant, and the flowers being produced on the leafy stems adds considerably to its beauty.

IBERIS GIBALTARICA HYBRIDA.—A new variety stated to be of hybrid origin. It forms a compact dense bush, each stem being terminated by a cluster of flowers varying in colour from rosy purple to white according to age. It is said to be quite hardy, and if so, we consider it one of the best additions to open-air flowers that has been

made for some time. Some admirably flowered plants grown in the open air were shown by Mr. R. Dean, Ranelagh Road, Ealing.

ODONTOGLOSSUM CRISPUM (hybrid).—An extremely handsome variety unlike others of a similar stamp with which we are acquainted. Its nearest ally seems to be *O. Andersonianum*, but the flowers are much larger with more attenuated sepals and petals, having a citron ground colour, heavily and copiously blotched with cinnamon-red. The plant was shown by the introducers, Messrs. Sander & Co., St. Albans, but the flowers were not fully developed.

PELARGONIUM FUTURE FAME.—A hybrid variety of the Ivy-leaved class, and one of the finest yet raised. Its growth is tall and slender, and it produces large trusses of flowers of a brilliant amaranth-purple, and of a larger size and better shape than those of other varieties in a similar way. Mr. George, Putney Heath.

BEGONIA DR. DUKE.—A double-flowered tuberous variety, one of the finest yet raised. Its blooms are large and very double, forming quite a rosette of petals, and the colour is a brilliant cherry crimson. Exhibited by Messrs. Laing & Co., Stanstead Park Nurseries, Forest Hill.

CARNATION FIELD MARSHAL.—One of the tree or perpetual flowering class. It is vigorous in growth, and appears to be very floriferous. The flowers are large, fully double, and bright scarlet in colour. Shown by the raiser, Mr. Turner.

AZALEA DR. HERMANN WEIGEL.—A variety of *A. indica*, with large double flowers of a bright rosy purple, produced plentifully even on small plants. Shown by Mr. Turner.

BEGONIA PRINCE OF WALES.—A double-flowered variety of the tuberous section, with unusually large rosette-like blossoms of a bright crimson colour. From Messrs. Laing.

PHILADELPHUS MEXICANA.—One of the finest of the Mock Oranges, and a lovely hardy shrub. It has large cup-shaped white blossoms, with a tuft of yellow stamens in the centre. Like most of the other species, it has a strong perfume. Cut blooms of it were exhibited by Mr. Walker, Thame.

FRUIT COMMITTEE.—A cultural commendation was awarded to Mr. Mortimer, Purley Park, Reading, for samples of a handsome new Cucumber which he has raised and named Purley Park Hero. The committee considered it to be "a handsome stock of the Telegraph variety." The fruits are large, spineless, and said to possess excellent flavour. Mr. Jenks, Brainlettye, was also awarded a cultural commendation for a very fine dish of Peaches which, had they been among the competing dishes, would probably have been first. Mr. Ward, Earl Radnor's gardener at Longford Castle, sent a new Melon called Longford Hybrid and some fine fruits of *Citrus medica*, for which he was awarded a cultural commendation.

THE ASPARAGUS COMPETITION.

The following are the prizes offered for the competition of the present year, which will take place in the Royal Horticultural Gardens at South Kensington on June 12.

PRIZES FOR GARDENERS IN PRIVATE PLACES, AMATEURS, AND OTHERS NOT GROWERS FOR MARKET.

For the best bundle of *Asparagus* grown by the exhibitor: 1st prize, £4; 2nd, £2 10s.; 3rd, £1 10s.; 4th, £1. The bundle of *Asparagus* is to consist of eighty heads. Prizes will not be given where, in the opinion of the judge, there is no merit. The *Asparagus* must be free of earth, and the bundles will be opened by the judges in all cases where they think it well to do so. No imperfect or "double" heads will count.

For the best fifty heads grown by the exhibitor, £2 10s.; second prize, £1 10s.; third prize, 15s.

PRIZES FOR MARKET GROWERS (ENGLISH BLOWERS ONLY).—For the market grower who shall exhibit the three best bundles, grown by the exhibitor, each containing one hundred heads, £5 5s.; 2nd prize, £3 3s.; 3rd prize, £2 2s. These

prizes are offered by M. Godefroy-Lebeuf, of Argenteuil.

The season generally is a fortnight later than usual as regards this vegetable.

NOTES OF THE WEEK.

TOMATOES DEAR!—We noticed some good home-grown Tomatoes in Covent Garden this week priced at the modest rate of 4s. per pound! What are our growers about? What use is made of our innumerable glass houses if our markets cannot be supplied in May with a vegetable so much in request? Less than one-fourth of this would give a good return for their culture.

COULSDON COMMONS, fifteen miles from London, near Catterham Junction, were formally dedicated to the use of the public on Saturday last by Mr. Shaw Lefevre, who with the Lord Mayor and a large party went there for that purpose. At a subsequent dinner at the Crystal Palace in celebration of the event, Lord Sherbrooke said that although he could not hope that there would be any immediate use made of these Surrey highlands, the time would come when the action thus taken would be justified. Mr. Shaw Lefevre said there was nothing but gratitude felt by the people of London towards the City Corporation for having secured for the public Epping Forest, Burnham Beeches, and Coulsdon Commons.

ATTENDANCE AT THE MANCHESTER SHOW.—Whatever effect horticultural exhibitions may have on gardening in general, there can be little question about the influence in a two-fold direction which the Manchester Whit week gatherings at the Botanical Gardens have had—first on the improved cultivation through the surrounding district of the various kinds of plants for which competition is invited, and secondly, by the diffusion throughout the district of a taste for these displays, as evinced by the numbers who yearly attend the shows. It is well, too, to bear in mind that the success of the Old Trafford exhibitions rests on horticultural productions alone. There are no extraneous attractions, such as supplement, and no doubt aid much in drawing the public at most of the great gatherings elsewhere in the provinces. The show just over has been the most successful the society has ever had, the attendance for the collective days being 55,500, and leaving, after all expenses are paid, a balance of just on a thousand pounds. On Whit Monday the number of persons who entered the Gardens was 17,000.

THE BRILLIANT WEATHER which we are now experiencing is a welcome change; indeed the heat in this part of Somerset is almost tropical. On this day (the 17th inst.) the thermometer, fully exposed at 7 p.m., but not in the sun, indicates 70°, and this with an almost clear sky and a rising barometer. It might truly be written this year that winter and summer have met without any intermediate season. So wonderful is the change in the aspect of the country, that we seem in the space of a few days to have been transferred to another region. In looking round the garden I find that Roses have suffered a good deal from the cold March weather, but on the other hand Pansies, Violas, Tulips, and similar hardy plants are making a better display than could be expected seeing how much they suffered from cutting east winds. Bush fruits have recovered wonderfully; Pears, too, are setting fairly well, but Plums so far are less satisfactory; Strawberries, although somewhat weak, are showing an average crop of flowers. The most promising of all hardy fruits is, however, the Apple. Many trees are literally sheets of pinkish white so thick is the bloom on them, and the fine weather which we are now having must do much towards securing a crop of fruit. Notwithstanding the unfavourable summer last year for ripening the wood, the trees were not overloaded with fruit; therefore they were able to perfect their fruit buds, a circumstance to which we are doubtless indebted for the fine display which they are now making.—J. C. C.

Recent garden appointments.—Mr. James Riddell, as gardener to Earl Feversham, Duncombe Park, Yorkshire; Mr. James Campbell, as gardener to Whalley B. Nutt, Esq., the Grange House, Edinburgh; Mr. James Brown, as gardener to Stephen Adam, Esq., The Lodge, Balerno; Mr. William Burnett, as gardener to J. J. Dalgleish, Esq., Braunton Grange, Culcross, Alloa, N.B.; Mr. John Harrison, as gardener at Thornycroft, Cheshire; Mr. Robert Slightholm, as gardener to T. Dymond, Esq., Burntwood Hall, Barnsley; Mr. John Birch, as gardener to Sir William Cooke, Bart., Wheatley Park, Doncaster; Mr. John George, as gardener to J. Kerr, Esq., Church House, Church, Lancashire; Mr. McKay, as gardener to the Duchess of Sutherland at New Tarbat, Ross-shire; and Mr. Macaulay as gardener and forester upon the Duchess's estate at Strathpeffer. Mr. G. Robertson, gardener to Mrs. Ellis, Invergarry, Fort Augustus, Inverness; Mr. J. Fleming, gardener to Mrs. Alcock, Eardmont, Crayford, Kent; Mr. E. Dumper, gardener to J. G. Bannatine, Esq., Summerville, Limerick; Mr. A. Barker, gardener to Earl Dunraven, Adar Manor, Co. Limerick; Mr. A. Langley, gardener to Dowager Lady Ripley, Bedstone Court, Salop; Mr. J. Bohill, gardener to Sir C. R. Boughton, Downton Hall, Shropshire; Mr. H. Mantelov, gardener to Mrs. Thompson, Inholm, Holmsbury, St. Mary; Mr. J. Todd, gardener to Sir J. C. Orde, Kilmory, Lochilphed; Mr. J. Robertson, gardener to Captain C. Hope, Cowden Knowes, Earlestone, Berwickshire; Mr. G. Beaton, gardener to Miss Ludlow, Yotes Court, Maidstone; Mr. W. Evans, gardener to F. Pine, Esq., West Tree Villa, Maidstone; Mr. A. Tait, gardener to A. Y. Herries, Esq., Spottes, Dalbeattie; Mr. G. McGill, gardener to A. F. Maclean, Esq., Ardgow, Fort William, N.B.; Mr. J. Rose, gardener to Sir R. Lloyd Lindsay, Bart., Lockinge, Wantage.

OBITUARY.

WE regret to have to record the loss of a good gardener, Mr. WILLIAM COX, who died on the 8th inst., aged sixty. He was upwards of forty years gardener at Madresfield Court; indeed, he was hardly anywhere else, for in his nineteenth year he went there as journeyman, in four years afterwards he became head gardener, and there remained until his decease, having during that time served four Earls Beauchamp, with credit to himself and satisfaction to his employers. He was the raiser of the Madresfield Court Grape, a hybrid between the Black Morocco and the Muscat of Alexandria, and also of Golden Gem Melon. His illness was long and severe, and a few months ago he had to give up the active superintendence of the gardens at Madresfield.

Manchester exhibition building.—In the report of the Manchester show (p. 456) the size of the new exhibition building should have been 252 feet long by 54 feet wide; not 25 feet long by 54 feet wide, as printed.

Lawn mowers.—Allow me to inform Mr. W. J. May, Walton-on-Thames, that I shall enter into no private arrangements with him in this matter until he signifies his willingness to fulfil the challenge (as proposed by himself and accepted by me) in the same public manner in which he made it.—AN OLD LAWN MOWER.

Rose Merville de Lyon.—In our report of the Regent's Park show in last week's GARDEN we stated that Messrs. Paul & Son, Chesham, received a certificate for this Rose, whereas it was shown by Messrs. W. Paul & Son, Waltham Cross, who also received a certificate for it from the Royal Horticultural Society.

Names of plants.—*C. D.*—1, *Geum montanum*; 2, *Rubus arcticus*; 3, *Sisyrinchium anceps*; 4, *Lithospermum purpureo-corneum*; 5 and 6, cannot name without flowers.—*Mrs. Tassell*.—Apparently *Rhododendron Nuttallii*.

H. M.—*Dendrobium thysiflorum*.—*Mrs. Ward*.—*Nephrolepis exaltata*—*T. R. Smith*.—*Cypripedium Hookeri*.—*C. M. O.*—Please send again.—*Hull*.—Apparently *Saxifraga aizoon* variety, *Tulipa Celsiana*, but the specimens are both too small to name correctly.—*T. Crisp*.—A species of *Vaccinium*; will endeavour to name it.

"This is an Art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES AND READINGS.

HARDY PLANTS AT MANCHESTER.—The Rev. F. Tymons has cleverly netted your esteemed correspondent, Mr. Brockbank, among the "florists proper" lately as an extensive grower, exhibitor, and raiser of florist's flowers, and one naturally turns enquiringly back to Mr. Tymons when we read the following from Mr. Brockbank himself last week on the hardy plants and alpine at the Manchester show. Speaking of the "melancholy sight" these plants presented through being grown under glass for exhibition purposes, he says, "If this is to be the future manner of exhibiting alpine, the Royal Botanic Society will certainly not foster a healthy love of Nature in our midst. It would have been easy to have taken a far more showy and better lot from any good collection of alpine, flowered naturally and in proper character, and this ought to be a criterion in judging as well as rarity and beauty of bloom." How does this affect the Auricula grower who has never grown or exhibited that alpine subject in any other way than that denounced by Mr. Brockbank? Forced or not forced, however, an alpine or hardy collection beats a table of Auriculas or of any special florist's flower, and such exhibitions are doing much to familiarise the rising generation of gardeners with select hardy subjects. Allowance can be made for protection and culture that hardly misleads anyone regarding the character of the plants; and without protection such collections could not be got together early in the year.

HORTICULTURAL LECTURES.—It is to be hoped the Royal Horticultural Society, under its new auspices, will not spend too much of its time in "lecturing." Among some who are listeners the long lectures are found to be a little wearisome if borne with patience. Lectures were a very good thing when no other means of disseminating information existed, but they are now a relic of bygone times, and occupy much valuable time that could be better spent in discussion and observation. Lectures can only be addressed to a very limited body of individuals—often sleepy ones. Meetings of scientific bodies and the like are now conducted on better "business" principles than they used to be. I think if a "British Horticultural Association" was to meet annually somewhere and record the discoveries and real work of the past year and its speculations for the future, it could say nearly all it had to say in lectures, and, like angels' visits, that are few and far between, they would be much better appreciated. The lecturers would also be more careful to have something to say, and their subjects would be less trite probably. Such an association does not need to encumber itself with a provincial flower show at the same time—all that is well taken off its hands now—but it might meet at the same place and time at which some of our great exhibitions are held. In this way gardeners would have placed before them a clear record of progress which at present they have no accurate means of estimating.

A HARDY GARDEN.—Those who are interested in the comparative merits of bedding *v.* hardy plants will in a short time have an excellent opportunity of comparing the two for decorative purposes at the Manchester Botanical Gardens, where a garden of popular hardy plants and another in the bedded-out style are laid out side by side. When we saw them last the bedded-out spring bulbs made the best show, but the hardy plants and annuals have not been long planted. Each bed of the latter contains one variety or species, such as Tritomas, Carnations, Delphiniums, Phloxes, Anemones, and other popular

and good things, not arranged perhaps as they would be in a private garden, but in a good way to test the merits of the varieties themselves if the experiment be successful, as no doubt it will be under such an able curator. The "botanical collection" which formerly occupied the same site has been relegated to the botanical border in a less public part of the gardens and nicely labelled.

MYOSOTIS GRANDIFLORA.—Without saying that this is a better variety of Forget-me-not than others in cultivation, there can be no two opinions regarding its perfectly distinct character. The plant is dwarf, erect, and close in habit, and the flowers are produced in broad, Cockscomb-like corymbs, borne at the top of stiff stout stalks partly fasciated, and often half-an-inch or more in breadth. Their colour is of the same turquoise blue as *sylvatica* and *disitiflora*, but they are more circular and even, like a good *Cineraria*; have from seven to nine petals against the other two's five, and have a larger and more distinct eye. The variety comes true from seed, and is very neat and pretty.

RED-LEAVED PLANTS.—Since the note on this subject appeared it has been suggested to me that the common Beet and its varieties, including the Mangold Wurtzel, contradict the idea that red colouring matter in the leaves renders a plant more hardy, as the dark-leaved Beets as a rule produce the smallest roots, and are the least hardy. When such varieties as Dell's Red-leaved Beet sport back to the greener leaf of the original type, the change is at once indicated by a taller and more vigorous growth. The same remarks apply to Rhubarb.

TULIPA RETROFLEXA.—In what light does the "florist proper" regard this flower, which represents probably the widest possible departure from his standard "cup of beauty" that could be conceived? And yet it is a handsome flower, with widely-separated petals of graceful curvature—just such an one as an artist would choose to depict, although the consistent florist would no doubt throw it on the rubbish heap. It is a conspicuous object in show collections of hardy plants at present.

RHUBARB.—Critics have not yet, so far as I am aware, affected to distinguish great differences in the favour of different Rhubarbs, and the only distinction cooks acknowledge between the sorts is measured by the quantity of sugar they require to sweeten them to the right degree. There are, however, green sorts and crimson sorts and coarse and fine textured kinds. The red sorts are, as a rule, the earliest and tenderest, and are most appreciated on account of their colour, for now-a-days colour is in the culinary art almost as important a matter as it is in the flower garden. Rhubarb is one of the most lucrative vegetable crops grown, whole fields being devoted to its culture near the large midland towns, where length and weight of stalk go for a good deal. When in season it makes a better tart than either green Gooseberries or green Grapes.

LONG GRASS LAWN MOWERS.—Lawn mowers were never designed to cut long Grass, that is, Grass 5 inches or 6 inches deep, notwithstanding the verdict of judges at "exhaustive trials" at shows and elsewhere. The idea of the mowing machine was borrowed from the cloth manufacturer's snipper, an exactly similar machine in use for shaving the pile of certain fabrics long before the lawn mower was suggested, but these cloth cutters are only adapted for cutting pile of a certain length, and the Grass mower is only adapted for cutting Grass about the length of half the diameter of the knife cylinder. Longer than that the knives miss their grip, or get too large a mouthful and "choke." Mowers of the present pattern adapted to cut long Grass could be contrived, but the power required to drag them would not come within the compass of a man or a horse,

hence for hay Grass and Corn resort is had to the reaper, constructed on an entirely different principle.

A CROP OF GRAPES.—The writer referred to in this matter lately in these notes has, I observe, fallen into an error in supposing that I set up an estimate of the crop he praises in opposition to his. This was not the case. It was his own estimate, not mine, which was given. He specified a certain area bearing a specified quantity of fruit which gave just less than 1 pound to every 2 square feet, and this result, after a fortnight's reflection I observe is not challenged. Extravagant eulogy ill assorts with arithmetic. How a writer who has for years grown Grapes himself could regard such a result as amazing, astonishing, murderous can only be explained on the principle on which the Lilliputians regarded Gulliver. As to packing Grapes, it was not "great, jutting shoulders" that were commented on, but the transparent apology offered for growing small bunches. Neither in theory nor practice can it be shown that large bunches will not pack and travel as well as small ones. One fails to understand the difference between a 20-lb. basket of big bunches and one of the same weight of small ones, such as fruiterers often receive.

EXHAUSTION BY PROPAGATION.—Has this idea any foundation in fact? It has been much insisted upon in connection with the propagation of new and scarce varieties of Vines and the like. The way these are propagated is as follows: Once the variety is proved, every plant, consisting necessarily of young one-year-old canes for the most part, is cut up into eyes and propagated. In other words, the Vine is multiplied from bits as fast as it will grow from its very infancy, and that is supposed to enervate its constitution and account for many of the failures in raising Vines that have been heard of, and the question that arises is, has the argument any force? Is a Vine propagated from an eye from good wood from an adult Vine stronger than one from a one-year-old cane propagated maybe for one or two generations from similarly youthful plants? and are Vines propagated by means of green cuttings? How far is the young plant influenced by the organised matter, stored up sap, or whatever you like to call it, in the original morsel of wood attached to the eye? After the young Vine plant begins to root fairly on its own account, does it soon become independent of parental assistance?

AS TO PROPAGATING VINES by the green tops, I do not think the plan is a ready or successful one, and it would be interesting to know in what nursery and with what particular Vine it was adopted extensively, as stated in the *Journal of Horticulture* lately. Mr. Barron, in "Vines and Vine Culture," says on propagation: "Roots are very readily produced from the old or ripened wood. But never under any circumstance do we see roots being produced from the young or growing wood; and although by great skill and care a few plants might be so propagated, the number would be very limited (p. 9)." This is the opinion of most growers. As a matter of practice one would therefore like to know when and where Vine cuttings were rooted in that way "as often as cuttings could be had." Such practice would be suicidal in the propagation of a new Grape from a commercial point of view, and of the growers who have raised or distributed new Grapes lately, we are pretty sure none of them adopted the plan. We have seen and examined many new young Vines sent out by the trade and by raisers, but never yet came on one not raised from a hard-wooded eye. Whatever answer may be given to the above questions, it may be safely stated that none of the characteristics or peculiarities of the new Grapes sent out originated in any way from debility by over-propagation; nor can it be supposed there is much in the hypothesis at all, or it would have been seen in other garden plants that have been multiplied for many years in succession by the

express method, as, for example, Roses on the Brier root and many other hard and soft-wooded plants.

PEREGRINE.

ORCHIDS.

EXHIBITION OF ORCHIDS.

SUCH a sumptuous feast of Orchid bloom as Mr. Bull has provided at his nursery in the King's Road, Chelsea, is in truth a rare and beautiful floral sight—a sight that reveals at a glance the wonderful range of colour and diversity of form that exists among exotic Orchids. No one, we imagine, even if he lacked predilection for Orchids, could fail to be enamoured with such a spectacle, representing as it does the loveliest and rarest flowers that the Tropics have yielded to us. Here we have them cultivated and flowered to perfection and arranged in a tasteful and picturesque manner in association with noble Palms, elegant Ferns, stately Aroids, and other plants. Under one capacious roof Mr. Bull has gathered, from every available source, seemingly, this vast assemblage of Orchids, which represents every important race of the family within the Tropics, from the hot jungles of the east to the cool mountainous regions of South America. The occupants of the hottest and the coolest houses, and even some hardy species, are thus associated, and all combine to render this unique show even more charming than its predecessor last year,—the second of Mr. Bull's special exhibitions of Orchids. The present display eclipses that of last season not only as regards the quality and excellence of the plants, but also in extent, for the length of the show house has been doubled, and now measures over 100 feet. This spacious house is filled to overflowing with flowering plants, which may be numbered by the thousand. The arrangement of this great gathering has been a work of care, for due regard has been taken to create harmony of colour and to prevent any harsh contrast. One striking feature above all others is the absolute freedom of the thickets of spikes which fall about elegantly without tie or stick to support them, and the absence of these imparts such a light, airy appearance to the plants.

The house has a broad central stage and a narrower one skirting the sides, and the Orchids rise as it were from a carpet of delicate greenery of Maiden-hair and Hare's-foot Ferns, which tends to throw up the brilliant hues of the flowers. Each end of the house is covered with mirrors, and these give a reproduction of the whole scene, so that the visitor appears to be looking through long vistas of gay Orchid bloom. These mirrors were a capital idea, as they considerably enhance the effect of the display. The brilliancy of this delightful Orchid show is heightened, inasmuch as it comes upon the visitor unawares, for before reaching it he has to pass through the entrance vestibule—a veritable grove of Tree Ferns, Palms, Cycads, and other luxuriant tropical-foliaged plants, which form a violent contrast to the gay tints of the Orchids. We like the way in which some of the varieties are grouped better than the mixed style, for when a colony, so to speak, of one or allied kinds is seen the fullest expression of beauty is derived from it, and such a style of arranging gives more variety, for then one side of the house is not a reflection of the other. The exhibition is remarkable not only for the enormous quantities of flowering plants it represents, but also for the wealth of species and varieties, some being extremely choice. To do, however, full justice in a notice of it would take up more space than we have at our disposal, so that we will confine our notes to the most prominent plants.

ODONTOGLOSSUMS are perhaps beyond all others the leading feature in the display, and particularly the undisputed queen of the genus, *O. vexillarium*, which was never more numerously represented in any one collection or seen in such diversity of forms or so uniformly well cultivated. Of this species alone there are some thousands of blooms expanded. In some cases a few plants form a little group by themselves, intermingled

with the graceful Ferns, which shows to advantage the delicate pink tints of the Orchids, the whole making a lovely picture. The most distinctly coloured varieties of *O. vexillarium* have been named, and some of these are remarkably distinct. There are about a dozen named varieties, the names in most cases being suggestive of the colour. Thus there are *atropurpureum*, the deepest toned of all; then comes *rubrum*, roseum, with every intermediate shade, to the pure white album, which is indeed an exquisite variety, the very embodiment of purity of colour and elegance of form. A very striking variety is *bicolor*, which has a pure white labellum, but rosy pink sepals and petals. *Pictum* and *picturatum* are in the same way, but distinct, the colours of the lip and sepals not being so contrasted. Another, called *amabile*, is truly a lovely variety, and so is *venosum*, remarkable for the distinct veins of deep rose-pink which traverse the light rose sepals, petals, and lip. It is marvellous to see so much variety in an Orchid that has been introduced so recently, and it is a pleasure indeed to see the plants in such perfection of health as Mr. Bull's Orchid growers bring this species to. The forms of *O. crispum*, too, seem to be endless, and likewise the hybrids which have sprung from it, but as we have so frequently alluded to the rich collection here of these, we will pass on to some of the other species, among which is *O. polyanthum*, represented by one of the finest varieties we have ever seen, only comparable with the handsome form shown by Mr. Lee at South Kensington a short time since under the name of *grandiflorum*. The difference between a poor and a fine variety of this species is very great, but those who possess a really good one such as that under notice certainly have a handsome Orchid. The large, bold flowers, with a yellow ground, so heavily blotched with chestnut-brown, renders it most attractive. Another rare variety here is *O. Jenningsianum pauciguttatum*, it differing from the type in the flowers having fewer spots. *O. perisigne* is one of the most beautiful of all *Odontoglossums* and quite new. The little white *O. Oerstedii* is flowering well, and very pretty it looks embosomed among a group of *O. vexillarium*. The spider-like *O. cirrhosum* throws up its tall elegant spikes above the rest, as also *O. cordatum*, of which there are some exceptionally dark forms of a deep chestnut hue; *O. nebulosum pardinum*, the rare *O. facetum*, *O. Halli*, *Coradinei*, and a new relative of it recently named by Professor Reichenbach *O. ligulare*, and *O. Ehrenbergi* are among the other species which contribute to the display, nor must we omit the queenly *citrosimum*, which is among the gems of the whole tribe of Orchids. Of this species, again, Mr. Bull possesses a whole host of varieties, the most distinct of which he has named according to their colours. That called *rubrum* is the deepest of all, then come *roseum*, *delicatum*, and the pure white album. *Giganteum* is for its unusually large flowers of a delicate tone of pink, and another named *punctatissimum* has its blossoms profusely spotted with minute dots of purple on a pink ground, thereby rendering it extremely beautiful. The long gracefully drooping spikes of *O. citrosimum* and the delicious odour they diffuse, together with the delicate colour, combine to make it one of the most valuable of Orchids, and one, moreover, that is more easily grown than many others. Leaving the *Odontoglossums*, we come to the

MASDEVALLIAS, which alone make an exhibition and afford quite a study, so numerous and diverse are they. Even of one species, *M. Harryana*, there are at least a dozen or more distinct varieties, all exceedingly beautiful. Mr. Bull wisely gives characteristic names to the most distinct, and of these named varieties there are no fewer than a dozen all more or less distinct either in colour, form, or size. The most remarkable structurally is the splendid *acanthifolia*, as rare as it is beautiful. The flowers are large, of a brilliant crimson-magenta, but its most palpable distinguishing character is the spiny process which occurs on the stalk of the leaf, which is seen in no other variety. Among the others is

one called *brilliantissima*, an appropriate name, as the colour is intensely brilliant, and so deep at the tips of the pointed sepals as if the colouring matter had run down to drop out at the points. Bull's Blood variety, *illustris*, *mirabilis*, *princeps*, *regalis*, *delicata*, *magnifica*, *Regina*, *lilacina*, *coccinea*, *splendida*, *sanguinea*, *cœrulescens*, *gloriosa*, and *ignescens* are remarkable for their splendid colours, which are simply indescribable, their being no pigments on the painter's palette with which to compare them. We noticed two that had distinctive names on account of the form of the flowers; one is *conchiflora*, the blossoms of which are shell-like, as if chiselled out of marble, so firm and thick are they. These numerous forms of *M. Harryana* contribute in no small degree to the display, for their sheaves of slender flower-stalks are seen peeping out at every turn. Of the winter flowering *M. ignea* there are two rare varieties in bloom named *Mas-sangeana* and *Stobartiana*, both extremely handsome. The flowers of both of these varieties are considerably larger than those of the type, and of rounder shape. The first is of an orange-scarlet colour; the other is of a lighter hue with the face of the flower distinctly lined with deep purple. *M. Veitchi* and *Lindeni* are, of course, included in the collection, besides numerous species of the less showy class, such as the charming little *Shuttleworthi*, which was originally introduced to this nursery; *M. Peristeria*, *bella*, *Chimera*, and the Humming Bird Orchid (*M. trochilus*) a fine plant of which in luxuriant health is carrying three or four of its exceedingly curious, though not very showy, blossoms. These and crowds of others of the so-called botanical Orchids are not, we observe, ignored by Mr. Bull, as they lend additional interest to the exhibition.

THE CATTLEYAS, with their gorgeous blossoms, are necessarily an important element, and they are in great profusion, particularly those such as *C. Mossiae*, *Mendeli*, *Warneri*, *Skinneri*, which are in the height of their flowering season. At every turn we meet them, some standing out boldly in an isolated position, others peeping from amidst the delightful greenery of Maiden-hair Fern, and others again are formed into a little group by themselves, where, as we before remarked, they are seen to the best advantage, as the extra brilliancy of one variety shows off the delicacy of another. Of the very variable *C. Mossiae* there is quite a crowd of varieties, scarcely two alike. Those that exhibit any remarkable characters are named, and the list of these named varieties is already a long one. The most prominent in flower are *Chelsoni*, *picturata*, *marginata*, with an exquisite white frilling to the labellum; *rubra*, the deepest tinted of all; *aurantiaca*, with a splendid yellow throat; *superba* and *gigantea*, the latter being remarkable for its unusually large flowers. In many instances the difference between these varieties is entirely one of colour, and the gradations of shades is so delicate, that it is quite impossible to intelligibly describe them; and the same with the forms of *Mendeli*, *Skinneri*, and *Warneri* Cattleyas, though there are some, such as *Mendeli delicatissima*, that are so distinct from all the rest, and so fascinating withal as to excite the admiration of everyone. Some dark forms of *Skinneri* were noteworthy, as also an exceptionally fine variety of *C. Leopoldi*, which stood out conspicuously from its fellows on account of its large blossoms and deeply pronounced markings. The greatest beauty, however, we thought of all the Cattleyas was a variety of *C. Trianae* named *Victoriæ*, one of the loveliest we have ever seen. The flower is large and the broad petals are held firmly together, so as to make a compact flower. The labellum is the chief feature of beauty, it being quite circular, beautifully frilled at the edge with pure white, while the other part is a glowing amaranth tint, and a bright blotch of orange-yellow extends down the throat. Rarely have we seen a Cattleya that pleased us so much as this one, which Mr. Bull rightly esteems highly. That magnificent ally of the Cattleya, *Lælia purpurata*, is a great beauty, and forms may be seen of it from the typical to the pure white alba, with sepals and

petals as white as snow in contrast with the richly adorned lip. The above are the principal of the Cattleyas at present in bloom, which very shortly will be succeeded by the splendid *C. gigas* and others of its race, and so carry the Cattleya bloom on till the end of the exhibition in July. Although the flowering season of

DENDROBES is on the wane, there are still a large number in bloom. There are some fine plants of the pretty *Devonianum*, with its long slender stems thickly wreathed with flowers, and *Pierardi* is likewise still in bloom. One of the gems of the genus is unquestionably *D. primulinum giganteum*, and here Mr. Bull has it to perfection, the stem being thickly clothed with the large shelled lipped flowers of a soft primrose yellow. The yellow *Dendrobies* are represented by *thyrsoiflorum*, *clavatum*, *chrysotoxum*, the rarely seen *dixanthum*, a sweetly pretty species, and *densiflorum*; of the latter there are some gigantic specimens some 4 feet through, bearing a perfect thicket of stout stems, from which hang in graceful profusion golden yellow clusters of bloom. Such grand specimens as these are so seldom met with that they well deserve a special note. The favourite little *Parishi* attached to blocks and flowering in profusion is one that never fails to arrest the attention, as also the white *Bensoniae* which must be included in every collection, however choice, and *D. Jamesianum*, *infundibulum*, *macrophyllum*, and the uncommon *cariniferum* may also be seen in bloom.

ONCIDIUMS make their presence felt, and the exhibition would be shorn of a deal of its brightness were it not for the long spreading spikes of *O. Marshallianum*, crowded with brilliant yellow blossoms comparable only to a swarm of golden butterflies. Then, again, the long dense spikes of *O. concolor* is nearly as showy as the preceding, but the finest of all the yellow species is undoubtedly *O. macranthum*, of which there is a grand specimen carrying a long branching spike of blossoms, each between 2 inches and 3 inches across, and of various shades of yellow, from a clear chrome to a bronzy hue. It is a veritable Goliath among *Oncids*. Among the rarities of the genus are the new *O. metallicum zebrium*, which has zebra-striped petals; *O. tetracopis* and *cryptocopis*, both of the serratum type, with chocolate-brown flowers on long rambling spikes. *O. phymatochilum* is flowered beautifully, and so is such as *leucochilum*, *unguiculatum*, *sphegiferum*, the latter in the way of the neat little *O. pulvinatum*, but a larger edition of that species and brighter coloured. *O. pubes* and the singular *O. unicorn*, with a horn-like process projecting from the labellum, and a host all help to lend interest to the display.

MISCELLANEOUS GENERA represented include the following: Of *Sobralia macrantha* there is a dwarf variety not exceeding more than 2 feet in height bearing large flowers of as rich and as deep a colour as we have ever seen in this *Orchid*. The summer-flowering variety of *Angraecum sesquipedale* is a noteworthy plant, as it shows that the normal season of flowering may be altered even in *Orchids*. Of *Cymbidium Lowianum* there are grand plants, sending out long spikes of their pea-green blossoms with the lips stained with crimson. This crimson varies in intensity considerably, and one form here named *atropurpureum* has the deepest tinted lip that had hitherto come under our notice. The ivory-white flowers of *C. eburneum* are still in perfection, though the season is so late for this *Orchid*. *Vandas* make a noble show, their stately growth being prominent among those of dwarf stature. Of tricolor there are many varieties, and one we singled out called *Meleagris* we thought particularly fine, the colour of the lip being so rich. The rare *V. Denisonianum*, with ivory white flowers, may be seen, and likewise a host of other East Indian species, such as *Aerides Fieldingi*, *crispum*, *Lindleyanum*, *odoratum*, *Saccolabium*, and others. The bright orange-scarlet spikes of *Epidendrum vitellinum majus* is everywhere seen, and among other flowering species of the genus we noted the rare *E. falcatum* or *Parkinsoni*, with its white

skate-like blossoms; also *E. glumaceum*, not often seen; and the *Frog Orchid* (*E. raniferum*) of peculiar interest, as some parts of its flowers strongly resemble a frog. The flowers are green and spotted, and depend in large dense clusters from the top of tall Reed-like stems. This *Orchid* by its singular appearance fastens the attention of almost every visitor. The *Lady's Slippers* contribute towards the show, and there may be seen potsful of the dainty little *Cypripedium niveum*, the whitest and sweetest of all the species. The *Javanese C. virens*, extremely rare in gardens, is to be seen, likewise fine specimens of such handsome species as *C. Parisii*, *laevigatum*, *Dayanum*, *Hookeri*, and *Acaule*. Other kinds we made note of included *Lycaste Skinneri* in great variety; *Phalaenopsis amabilis*, with long, elegant spikes of white moth-like flowers; *Anguloa Clowesi*, with its large yellow Tulip-like blossoms; *Laelia majalis*, the lovely *Flor de Mayo* of the Mexican natives; *Eulophia scripta*, a species not often met with, but pretty in colour and elegant in growth; and *Phaius Wallichii*, *Calanthe veratrifolia*, whose spires of blossoms rise above all the rest, and help to create diversity of outline.

These are some of the chief elements in this exhibition, but any description fails to give an adequate idea of it, for it must be seen to be realised. It has already been visited by a great number of the nobility and gentry, and we believe Mr. Bull intends to keep it open until the latter part of July, but the best time to see it is now and during the next month.

Odontoglossum citrosimum album.—

By far the finest example we have seen of this lovely *Orchid* is sent us by Mr. Soper from his garden at 307, Clapham Road. The flower-spike, produced from a large plump bulb, measures in its full length just upon 2 feet, and quite half of its length is furnished with large blossoms of waxy whiteness, with only a dash of golden yellow in the centre to mar their chaste purity. No fewer than twenty-five flowers were borne on one spike, which was branched in its upper part. Mr. Soper seems to be particularly successful in cultivating this *Orchid*, for last year we had to note a fine specimen of it from him. We hope soon to give a coloured plate of this *Odontoglossum* and its varieties.

A fine *Cattleya Mossiae* flower is sent us by Mr. Allan, Lord Suffield's gardener, at Gunton Park, Norwich. It is one of the finest flowers we have ever seen. From the tip of the upper sepal to the end of the labellum it measures 8 inches, and is just the same dimensions across the lateral petals, which are both 3 inches in width. The sepals and petals are of a deep pink-mauve tint, and the labellum, which measures 2½ inches across, is of a rich amethyst on the lower part, while the throat is a bright orange-yellow. The margin is exquisitely frilled, and is of a lighter tint than the other part. Mr. Allan says in his note, "I bought the plant of a new importation that had not flowered some four years ago of Messrs. Veitch. Two out of the four I bought have turned out to be grand varieties; the other plant has had fifteen flowers on it, and I fancy all the plants are worth as many guineas as they cost shillings."

Odontoglossum Halli magnificum.—

A plant so named was shown at South Kensington last week from Mr. Pollett's collection at Bickley, by his gardener, Mr. Wilson. It represented, without doubt, the finest variety that has ever been seen in this country of this handsome *Orchid*, and well it deserves the name of *magnificum*, for even the finest of the varieties we had hitherto seen were poor compared with it. The flowers were some 5 inches across, the sepals and petals being broad in proportion, and the lip extremely large. The ground colour was pale yellow, and the dark blotches and spots were uncommonly heavy. The plant was a fine one, and bore two flower-spikes, one carrying ten the other eleven flowers. The plant altogether bore evidence of skilful culture, and the committee awarded the exhibitor a cultural commendation, though why

such an extraordinary fine variety as this was not considered a fit subject for a first-class certificate is one of those queries probably only answered by the members of the committee, who the previous meeting were so lavish with certificates, awarding them to third and even fourth-rate plants.

FERNS.

THE BEAUTY OF YOUNG FERN FRONDS.

AMONG plants with handsome foliage none possess such delicate tints as are to be found among Ferns, especially at this time of the year, when the young fronds are unfolding. To those who look upon Ferns as masses of unvarying green I would say, Come in either the cool or the warm ferneries, and see in the first the most delicate tints of *Adiantum decorum*, whose young fronds, produced by dozens on ordinary sized plants, are of a pale, tender, yellowish green, edged and suffused over with rosy pink, which tint they retain for a long time, forming thus a very pleasing contrast with the dark, rich colour of the outer matured fronds. A similar tint is also observable in *Osmunda palustris*, another essentially greenhouse Fern of larger dimensions, which differs from other *Osmundas* by being thoroughly evergreen, thus adorning the cool house with its delightful light-coloured foliage all the year round; while among the dwarf kinds requiring little or no artificial heat at all nothing is more attractive than the prettily-coloured

PELLEAS, whose glaucous hues give them such a conspicuous appearance during all seasons, but principally now that a fresh beauty is imparted to them by their delightful pale bluish spring growth. Foremost among them is the now very scarce *P. cordata*, whose fronds, averaging about a foot in height when fully developed, stand nearly erect, thus showing to perfection the heart-shaped pinnæ, which are of the most pleasing form, and their natural and pretty glaucous colour all the more showy on account of the stipes and rachis being straw colour; then the gracefully pendulous *P. flexuosa* with beautiful fronds hanging down and showing themselves to perfection when grown in a basket near the glass. *P. ternifolia* also requires to be grown in the same way to show to the best advantage its prettily coloured fronds, which are rendered more attractive still by their curious and uncommon shape, the pinnæ being disposed in whorls, forming little stellate clusters of pale blue foliage set at equal intervals all along the thin black stem, which is no stouter and as shining as that of an *Adiantum*. The charming *P. andromedefolia*, *atropurpurea*, *ornithopus*, *Bridgesi*, *brachyptera* would, in fact, furnish sufficient materials for a special study, but as I am here treating of their colours alone, and as they nearly all possess the same refreshing tints, it will not be necessary to describe them all. This same delicate glaucous tint is not restricted to dwarf-growing *Pelleas* alone, for in the greenhouse what can be more effective than that highly decorative old favourite,

POLYPODIUM AUREUM, or the scarcer and more distinct still *P. sporocarpum*, both strong growing kinds, and making a very pleasant effect in the fernery, where the bold and massive foliage of the former, of quite a blue tint, forms a singular contrast with the colours of those around it? The latter species, although of a somewhat more rigid habit, is nevertheless one of the handsomest coloured Ferns in cultivation, and wherever it is placed cannot fail to attract attention on account of its erect fronds, deeply pinnatifid, slightly waved, and very glaucous. Then, again, in the cool house there are now to be seen and admired the lovely *Adiantum fulvum* and *pubescens*, as well as the curious *Davallia Tyermani* or the *Doodia aspera* and the variety *multifida*—all species of small dimensions, and whose foliage at this season bears a lovely metallic tint, which is also shared, and even to perhaps a more marked degree, by the strong growing kinds of Japanese *Lastreas*, such as *L. erythrosora*, of large and handsome proportions, and producing fronds in great abund-

ance; *L. opaca*, with leathery fronds possessing very lasting properties; the comparatively new and charming *L. prolifica*, which has all the appearance of a finely-cut form of *L. erythrosora* as to the mode of growth and the glorious tint of its elegant fronds, which are besides covered with young plants, produced as plentifully as on the fronds of *Asplenium bulbiferum*. *Lastrea varia*, a species seldom seen in cultivation, is particularly remarkable by the rich, glowing, velvety metallic colour which covers its young fronds, which afterwards turn of a splendid dark velvety green. If we add now to the above list the highly interesting *Woodsia polystichoides* Veitchi, with its foliage rendered like a sheet of white silk by the numerous brilliant scales covering the fronds, and also the many tints of green, varying from the palest green of *Adiantum venustum* and *Lomaria discolor bipinnatifida* to the dark colour of the foliage of *Pellaea rotundifolia* or of *Polystichum venustum*, we shall have an array of colours not to be equalled in any other classes of plants. It is not, however, in the greenhouse that the many-tinted fronds are mostly found; these are brighter and also in greater numbers in the stove, where, no doubt, a greater amount of heat is particularly suitable for the development of the colours, and where

ADIANTUMS of course form the predominating element and surpass in brightness as well as in variety of forms and habits any of the other Ferns. Indeed, the extraordinary tints of some, such as the charming little *A. rubellum* with suberect fronds varying in colours from the yellowish pink, which they assume when they don their spring foliage, to the magenta and then the bright purple border which is peculiar to them in their further development, also the bright carmine of *Adiantum macrophyllum* with large pinnæ of a peculiar shape, and the brilliant rose turning later on to the beautiful copper colour that is found in *A. Hendersoni*, all combine to make that this interesting group *par excellence*. For instance, look at the fascinating dwarf *A. Legrandi*, whose close and yet elegant fronds form a beautifully compact head, appearing as it does when loaded with half developed fronds or over-suffused with the brightest colour. The same might be said of the commoner *A. gracillimum*, which can hardly be surpassed for gracefulness when grown in a basket and near to the glass, which treatment seems to completely alter its habit, the young fronds, light and feathery, being then of an intense rosy pink. *A. concinnum*, *tinctum*, and *Ludemannianum* are also among the gems of a good collection, the latter especially with its pinnules brought into a small tuft and forming a little rosette, in which, if grown near the light, will, at this time of the year, be found not only many shades of green, but also a very attractive pale magenta edge. And among the larger growing kinds where is there in other foliage plants anything to approach the delightful and subtle tints found in a well-grown frond of that queen of the Maiden-hairs, *A. farleyense*? When it has been kept near the light, instead of having the sickly yellowish appearance which is so detrimental to its well-being, if the temperature of the house has been kept up to between 65° and 70°, and if the plant has at all times enjoyed an abundance of moisture at this season, the pinnules are of a pale green, relieved by a wonderfully pretty purplish border, adding another to the very numerous charms it already possesses. Then, again, the lovely *A. Veitchi*, the gigantic *A. cardiophyllum*, with fronds 3 feet to 4 feet high, of a pale green when mature, but of a beautiful semi-transparent rosy colour in their young stage; the elegantly pendulous *A. peruvianum*, with unusually broad pinnules of a delightful metallic tint when young; and lastly, the beautiful *A. Williamsi*, of comparatively recent introduction, most distinct and conspicuous among all others by the pale green, almost yellow, tint of its long hanging fronds formed of prettily rounded pinnules of a peculiar shape. This species by-the-by does much better in a basket for which it is well adapted than for pot culture where it has the tendency to become of a straggling habit,

like all pendulous plants, however graceful they may be, if they are grown without due regard to their requirements. The only way to make a good plant of *A. Williamsi*, if it must be grown in a pot, is to have it placed above all other plants, as at the Victoria and Paradise Nurseries, where it is the admiration of everyone, but I should think it better and certainly more natural to grow it in a suspended basket, as in large fernery at Kew Gardens, or some smaller specimens also grown suspended from the roof at the Royal Exotic Nursery, Chelsea.

DIDYMOCHLENA TRUNCATULA is one of the most effective of Ferns with copper-coloured young foliage, and as it is a strong grower and a handsome habited plant as well, it follows that it has become a general favourite wherever it has been introduced. The same also with the truly magnificent *Davallia polyantha* (divaricata), which produces immense fronds gracefully arching over, and whose colour may safely be termed chameleon-like, as before they reach the dark glossy green which is peculiar to them these fronds pass through a whole series of tints and shades from the deep purple to magenta, then to light bronze, &c., and all these transformations only require a few days to take place, and as the plant is evergreen and grows all the year round, there are almost always some richly coloured fronds on it. Another species, *Brainea insignis*, still scarce in cultivation, but promising to become plentiful, as a host of seedlings have been raised lately, also possesses very handsomely coloured foliage, which can almost rival the better known, although rare, *Lomaria l'Herminieri*, of dwarfier stature and more sturdy habit, whose bright long fronds are produced in abundance all through the summer. Besides that all the various shades of green found in the ferneries at this time of the year help to make them very attractive, especially when the fernery is carpeted with many-coloured *Selaginellas*, such as the beautiful *S. cæsia*, *cæsia arborea*, *Kraussiana aurea*, *rubella*, and others, as is happily the case in many well-cared-for collections where Ferns and *Selaginellas* receive the kind attentions that they so well deserve, and which little extra trouble they repay so well.

With a view to help those who would like a good collection of Ferns which have their young fronds coloured, I have drawn up the following list, which, though not exhaustive, is sufficient to show how numerous they are:—

<i>Adiantum aneitense</i>	<i>Doodia aspera</i>
* <i>cardiophyllum</i>	<i>multifida</i>
<i>colpodes</i>	<i>candata</i>
<i>concinnum</i>	<i>Goniophlebium appendiculatum</i>
* <i>latum</i>	
<i>decorum</i>	* <i>Lastrea erythrosora</i>
<i>Edgworthi</i>	* <i>opaca</i>
* <i>farleyense</i>	<i>prolifera</i>
<i>fulvum</i>	<i>Steboldi</i>
* <i>gracillimum</i>	<i>varia</i>
* <i>Hendersoni</i>	<i>Leucostegia immersa</i>
<i>Legrandi</i>	* <i>Lomaria chilensis</i>
<i>Ludemannianum</i>	<i>l'Herminieri</i>
<i>macrophyllum</i>	<i>Osmonda japonica corymbifera</i>
* <i>pentadactylon</i>	<i>palustris</i>
* <i>peruvianum</i>	* <i>Phlebodium aureum</i>
<i>pubescens</i>	<i>sporodocarpum</i>
<i>rubellum</i>	<i>Platylova atropurpurea</i>
* <i>Sanctæ-Catherinæ</i>	<i>brachyptera</i>
<i>Seemani</i>	<i>andromedefolia</i>
<i>tinctum</i>	<i>Bridgesi</i>
<i>Veitchi</i>	<i>flexuosa</i>
* <i>venustum</i>	<i>ternifolia</i>
* <i>Williamsi</i>	<i>Woodsia polystichoides</i>
<i>Athyrium Goringianum</i>	<i>Veitchi</i>
<i>tricolor</i>	<i>Selaginella africana</i>
* <i>Blechnum corcovadense</i>	<i>atroviridis</i>
<i>occidentale</i>	<i>cæsia</i>
* <i>Brainea insignis</i>	<i>arhorea</i>
* <i>Davallia Mooreana</i>	<i>Kraussiana aurea</i>
* <i>polyantha</i>	<i>rubella</i>
<i>Tyermani</i>	
* <i>Didymochlena truncatula</i>	

The kinds marked thus (*) are strong growers.

S.

Gymnogramma "gloriosa."—Under this name M. Linden, of Ghent, showed at South Kensington last week a beautiful Fern which appeared to be the same as that shown at the late Ghent show by M. Maron, under its true name, *G. schizophylla*. It is unquestionably an extremely finely developed specimen of this specimen, but it

certainly does not appear to differ sufficiently from the type to justify even a distinctive varietal name much more a new specific name, and that an absurd one, for a Fern. Dubbing plants with unauthoritative names can only lead to confusion, particularly when the new names are intended to supplant the recognised ones. *G. schizophylla* is one of the loveliest Ferns that has yet been introduced, and no better example could possibly be seen of it than that shown by M. Linden.—*FILICES.*

A novel Fern basket constructed of Ivy stems as thick as a man's finger is sent to us by Mr. E. Sandford, gardener at Dale Park, Arundel, who says he has made a quantity of them for suspending Ferns in. The basket is about a foot in length, and is sugar-loaf shaped, the diameter of the widest end, which is the mouth, being 6 inches. The stems are held together firmly by zinc wire. The basket has a rustic appearance with the stems clothed with shaggy, dry roots, and here and there sending out green leaves.

Drymoglossum piloselloides.—The reviewer of "Indian Ferns," after giving a good description of this *Drymoglossum*, states that he is not aware that this species has ever been brought home in a living condition, having never seen or heard of it being in any collection. For the benefit of your readers, particularly those who are lovers of Ferns, I wish to state that there is a living specimen of this Fern in the collection here. I am not acquainted with the length of time during which we have had it, but it is now growing freely, and gives promise of being in a flourishing condition in the course of a few months.—*THOMAS JENNINGS, Botanical Gardens, Sheffield.*

THE BEST CULTIVATED FERNS.

(Continued from p. 418.)

DAVALIA TENUIFOLIA STRICTA, a native of the Pacific Islands, is no doubt only a handsome form of the before-mentioned species, of the same mode of growth, being also deprived of rhizomes; but it is a much stronger grower, its more robust fronds often reaching the height of 3 feet. They are erect, with pinnæ broadly cuneate, and of a very pleasing colour. This forms a very decorative plant in a short time, and is exceedingly useful for indoor decorations. It is also one of the Ferns whose fronds last a very long time when cut and mixed with flowers. Greenhouse.

D. TENUIFOLIA VEITCHIANA.—An extremely beautiful variety from the East Indies of recent introduction. It is by far the handsomest of all the *Davallias* without rhizomes. Its elegant feathery fronds, from 2 feet to 2½ feet long, are borne on slender stalks of a rosy colour, which contrasts singularly with the pale green of the pinnæ, cuneate in form and finely cut. Although of robust growth, it is most elegant in its general outline, as the fronds, which are produced in great abundance, are tripinnate and ovate-lanceolate in shape, with their edges slightly incurved; the light pinnæ loosely set give the plant a very plumose and delightful appearance. It makes a very fine object when in a basket suspended from the roof where good space is allowed all round, so that its fronds can develop freely. Stove.

D. TYERMANNI.—This very striking species is distinguished at first sight by its slender rhizomes, which are densely clothed with large silvery white chaffy scales. They produce, but rather sparingly, handsome deltoid tripinnate fronds, triangular in shape, about 8 inches or 10 inches in length and of about the same breadth at the base; the pinnæ, cuneate in form, are finely cut and rich dark green in colour. This species is exceedingly useful for covering dead Tree Ferns, on the stems of which it grows apace and makes a very pretty object, the silvery points of the rhizomes peeping out in all directions. Greenhouse.

DENNSTADTIA.—This genus is composed of beautiful and mostly strong-growing Ferns, provided with creeping rhizomes which differ from those of *Davallias*, inasmuch as they require to be kept underground, or partly so, to be of any benefit to the plants. Most of the species possess a bold

stock of hardy plants, was favoured by Mr. Nelson with the stock of this plant, which seems to be a free seeder. He doubts if it should be classed as a perennial, but time will settle this point. At any rate there is no doubt but that the best habited kinds may be increased freely by cuttings, and if that be so, its value is much enhanced, not only as a border plant, but also for pot culture. It may be asked why, if coming so freely from seed, should it be propagated by means of cuttings. To that query there is a reasonable reply. From seed the hybrid assumes various habits and characters more or less desirable, the very best forms being seen in the beautiful plants shown at Kensington by Mr. Dean, whilst others, if less showy, are so only because they are so very dwarf and tufty, and seemingly are as pretty for rockwork as could be conceived. Then, though the suffused tint pervades all the flowers, none are of poor quality. Again, all those seedling plants which have pale or woolly foliage are tender, and do badly. If only the best form be selected, no doubt the seed stock will presently become quite set and true, although there is a botanical theory prevailing that the seed progeny of true hybrids always exhibits a tendency to revert to the types of its parents. However that may be, it is interesting to find that a hybrid is so fertile in the production of seed. A plant of similar habit, and not less beautiful, the hardy *Cheiranthus Marshalli*, held to be a true hybrid, is, however, quite barren. So much has been done by selection from time to time by persevering florists, that there can be little doubt persistent effort will presently overcome the hybrid's erratic nature, and create a strain that shall be as true as can be desired.

J. K.

THE WHITE TRUMPET DAFFODILS.

A VERY interesting chapter could be written on the different varieties of the white Trumpet Daffodil, but at present we are concerned with what are supposed by the older writers to be natural varieties. Parkinson assigned them to Spain, and, so far as the knowledge possessed by the present generation of amateurs, there is no proof either for or against Parkinson's statement. Haworth describes four varieties of these, but at present there are only three in cultivation, and form the subjects of the woodcut representing the flowers half the natural size. No. 1, the largest, has a remarkably long trumpet, terminated by an elegant rim-like flange, and on first parting from the perianth is a pleasing sulphur colour for a few days, when it changes to white. The divisions of the perianth in a good specimen of this variety are considerably shorter than the trumpet; it is called *albicans*. No. 2 is a somewhat smaller flower than No. 1, with a straight trumpet, which slightly expands at the mouth and is elegantly scalloped; when first opening the trumpet is light sulphur, but very quickly becomes white. The divisions of the perianth are somewhat shorter than the trumpet and more or less twisted; this is called *tortuosus*. No. 3 is the smallest, and it may be said the most elegant, differing mainly from No. 2 in the divisions of the perianth being as near as possible the same length as the trumpet. This is called *cernuus*, and is supposed to have given the two beautiful double white Trumpet Daffodils, now very scarce.

At some future time I may give some account of the new beautiful white hybrid Trumpet Daffodils, of which I have several in my collection, but only two kinds in sufficient quantity for commercial purposes.

PETER BARR.

12, King Street, Covent Garden, W.C.

Birds destroying Primroses.—Birds have been very destructive here this spring in picking off the blooms of the various kinds of Primroses. Some plants they pulled off every one, completely covering the ground round the plant. Nor did they confine themselves to the garden kinds, but helped themselves with some of the common kinds we have in shrubbery borders, the double sorts as well as single. Some have thought

it was for want of water; others think there is some insect they get from them. Be this as it may, I watched the chaffinches pull the flowers off and throw them on the ground, and did not appear to pick anything out of them. They quite spoilt them this season. This is the first time they have done so.—J. C., *Farnboro'.*

HARDY PLANTS AT THE MANCHESTER AND LONDON SHOWS.

OPINIONS will vary as to the character of the exhibition which took place at South Kensington last week, but my own opinion is very decided on the matter. I think that it can hardly be questioned that there is a lamentable falling off in the character of all our metropolitan exhibitions. The Crystal Palace is but a shade of its former self; and although there was a slight improvement this year, yet those who remember it in days gone by must surely write "*Ichabod*" on its glories. The Botanic, by far the prettiest of the three, shows manifest symptoms of decay; and although it secures what the Royal seems unable to do, the patronage of some members of the Royal Family, yet it cannot secure the collections of plants that it at one time did. It is a delightful promenade, and on a bright sunny day such as it had this year nothing can be more charming than the appearance of the gardens, so happily laid out by Mr. Marnock, when the fashionable world flock in thousands to enjoy the same. As to South Kensington, the show seems to be going down the broad incline which the Society itself has so rapidly been taking. It had not even the attractions of the Botanic; there was no space for a promenade, for all the space round was filled up with implements, while an unpleasant odour of fish and cookery made itself very manifest the moment one left the tent, and I met with no one who did not feel the same kind of despair as to the Society's position. We are sometimes told that the frequency of these exhibitions in London has detracted from their popularity. Now, an *habitué* of these shows is hardly a fair judge on such a point; he is *blasé* with them. I could, before entering the tent at South Kensington on Tuesday last, have pretty well indicated what plants would be there, and who the exhibitors would be; but although the same thing holds good at the Botanic, that does not prevent thousands of people from attending, and the same with the Crystal Palace. But the simple truth is, the gardens at South Kensington are not a fashionable lounge, and horticulture fails to win its way.

But whatever opinions may be held on the merits of the show as compared with the Whitsuntide exhibition at Manchester, there can be no question that in two classes of plants, representing, if I may so say, the two extremities of the horticultural scale—Orchids and herbaceous plants—there is a woful distance between the merits of the two exhibitions. We have many large and successful growers in and around London, but, as a rule, they are conspicuous by their absence. Well, if I had a collection of Orchids I should probably do the same. I should hardly like to expose choice plants to the possibility of cold and even frost for two days. In Manchester all this is provided for in the heated show house; the same reason does not hold with regard to the herbaceous plants, for if Orchids are the aristocrats of horticulture, these are without doubt the bourgeois; if the one is the rich man's hobby, the other is one which even the cottager can indulge in; and yet what a miserable display—if display it can be called—these made the other day at South Kensington, and evidently how very different to that at Manchester. I had not the pleasure of being there this year, but those shown last year by Mr. Brockbank, Messrs. James Dickson & Co., and others gave a rich treat to all lovers of this class of flowers. Of those exhibited at South Kensington the other day, I can emphatically say they were rubbish, and hardly worthy even of the second prize which was awarded them. Why is this? Why does not Mr. Ware, who surely owes much to the revived

fancy, do something to show the world what treasures there are within their reach? Mr. Parker, of Tooting, used to do them well, but he is no longer a grower of them. I have heard many men say, "Oh! I can sell enough without exhibiting." I do not think this is quite right; it may be so, but at any rate let us see these things. We have private growers, too, around London whose gardens are famous for these things. It is all very nice for them to expatiate on their beauties, but surely they would be conferring a kindness on their fellow-mortals were they to bring them forward on such occasions, for I can truly say that if anyone wished to take up their culture, and went to the show the other day, he would come away with the strong determination to have naught to do with them.

I am quite at one with Mr. Brockbank as to the absurdity of showing large forced masses of flowers as herbaceous plants where the character is altogether gone. For instance, I saw a mass of *Opuntia Rafinesqui* shown at Manchester last year, with large leaves and large expanded flowers, which had evidently been brought forward in a greenhouse with artificial heat. How deluded a person would be who imagined he was going to grow it in the open ground in the same manner. I believe the most satisfactory way would be to have two classes, one of sturdy alpine plants, limiting the height at which they were to grow, and the other of herbaceous plants; and excluding Lilies from these, there are ample materials for both classes of exhibits, and it would tend, if rightly done, to a greater interest being taken in the cultivation of these valuable plants—valuable, not as Orchids are valuable for the high prices which they bring, but valuable as affording at all seasons of the year something to please, and it is with the hope of helping forward this good end that I have made these few remarks on the exhibits of herbaceous plants at Manchester and London, and have shown how much we have, as in many things, to learn of these enthusiastic exhibitors. I am a rigid florist where florists' flowers are concerned, but ready to acknowledge and welcome beauty wherever I see it. DELTA.

LILIES OF THE VALLEY EXPOSED AND IN SHADE.

EVER since I was a boy I have been taught to believe that the only satisfactory way of growing Lilies of the Valley in the open air was to plant them in a shady place. It did not matter whether the crowns were to be taken up and forced, or whether they were to be left to flower at their own time; it was thought that growing them in the shade was absolutely necessary, in order to secure fine plump crowns that would give fine spikes of flowers. I am willing to grant that, in some soils and in favourable situations, the practice may be right, but it does not necessarily follow that it is applicable to all cases. Having to deal with this Lily where it is required in rather large quantities, and in a soil and situation unfavourable to an early maturation of the crowns (a most essential point when required for early forcing), I find that when they are prepared for forcing by being grown in a shady position, the result is not by any means satisfactory. There is not only a scarcity of flowers, but the few that are produced are poor and weak, a result attributable to our cold, ungenial soil and high situation. Finding this to be the case, some years ago I decided to prepare my stock for forcing by planting them in the full sun, and the result, I am glad to say, is eminently satisfactory. The preparation of the soil has been in no way unusual, for we always make it fairly rich by the application of well-rotted manure. In order to keep up a supply of plants, we have to make a fresh plantation every year; and as it takes three years to secure fine strong crowns, some amount of forethought is necessary to prevent a break in the supply. We select a position for our Lilies in the narrow borders of the kitchen garden, which lies well to the sun. Generally we make new plantations in April, just as the young growth is peeping through the soil, but we are not very particular in this matter. If work presses, we

plant as soon afterwards as may be convenient, and I should not hesitate to plant in June. If well watered after planting, and the border is kept shaded for a week, the plants soon take hold of the new soil, and are but very little the worse for the change.

Respecting the advantages of growing Lilies of the Valley in a sunny position when required for forcing, little or no argument is necessary. Between those grown in the shade of a wall or a building and those grown fully exposed there is at least ten days' difference in the starting into growth in spring, that is to say, those plants which have the benefit of the sun are ten days earlier than those grown in the shade; and if there is that much difference in the early growth, it seems clear that there must be a corresponding forwardness extending through the summer, viz., those grown fully exposed are earlier in coming into flower than those in shade. There must, too, be an earlier maturation of the growth, so that from the first stage to the last there is a decided gain. Experience proves this to be the fact, for the foliage of those grown in the open garden dies away fully three weeks earlier in autumn than that of plants cultivated quite in the shade; and no one experienced in early forcing need be told that the earlier any plant goes to rest in the autumn, the better condition it will be in for forcing. It not only responds more readily to artificial heat, but the flowers or fruits will be finer, owing to their having had a longer resting time. It is proper to remark that we force our Lilies in boxes made specially for our use at the Weston-super-Mare potteries; they are 28 inches long, 6 inches deep, and 9 inches wide. To fill these boxes closely with crowns, we grow them thickly on the ground; therefore we simply drain the boxes, and put 2 inches of soil in the bottom; then we take them to the bed, and with an edging knife cut out the crowns in masses exactly the size of the box in which they are placed without disturbance. A little fine soil shaken over the surface makes all neat and tidy. A thick layer of green Moss is then laid on the surface, with a view to start the crowns in darkness, and then the boxes are taken to a cold pit for a week or two prior to being placed in heat. On the subject of planting it may be truly said that Lilies of the Valley may be planted at any time; but unquestionably the earliest results are obtained from spring planting. When, however, this is not possible, they may be removed with perfect safety at any other time, if only ordinary care is observed, and the succulent roots are not allowed to remain exposed to the air for too great a length of time.—*Field*.

Raising Anemone coronaria from seed.—I should like just one word more about these flowers to correct "S. D." in his assumption that I have either advised or practised the sowing of seed in heat. I have advised the sowing of and do practise the sowing of it under glass, but not in heat, because heat is not at all needed to induce it to germinate freely. Were the notion to get abroad amongst amateurs that heat was necessary to induce germination, it might seriously tend to make unpopular one of the hardiest, easiest grown, and most beautiful of garden flowers. It is all very well to practise sowing in the open ground when the grower has ample seed and a genial soil in which seeds can germinate freely, but it is not every one who is so fortunate. Those who have but a seedman's packet to start with will do well to sow in shallow pans or boxes, and when the seedlings become thick and strong shake them out singly and dibble them 6 inches apart each way into a bed of rich, well-prepared soil. No practice can be simpler or more successful, and, what is important, every seedling plant is utilised. I recommend shading the seed pans with newspaper or some similar thin substance, until the seed has germinated, and specially so is it desirable that amateurs should take such trouble, because they are not always at hand to see that water is needed at a critical moment. The seed will not be a bit longer in germinating on account of the shading, which need only be given during the hottest hours

of the day. I have plenty of seed to sow, but I could not trust it outdoors in such tenacious soil as I have here. I have had truly beautiful flowers from seed sown in the middle of June.—A. D.

"Golden-leaved" Cow Parsnip.—Will your correspondent "J. M." Charmouth, be kind enough to spare me seedlings or seed of his gold-leaved Cow Parsnip? There is a magnificent plant lately imported from Japan called *Heraclium Frederici splendens*, which I can recommend to "J. M." It is to be obtained of M. Mater, Leyden, Holland. It is a large variegated kind. Some years ago a correspondent of THE GARDEN mentioned a variegated Rhubarb in his possession. If any reader of this has such a plant, I would be most grateful for a little seed.—FRANK MILES, *Bingham, Notts*.

Names of Poppies.—We agree with your correspondent, Mr. Denis Knox (in your issue of the 12th inst.) that the nomenclature of the Poppies is undefined. This may be mainly attributable to some Continental cultivators, who obtain their supplies from uncertain sources, and thus propagate the errors in this country. There are two varieties of *P. orientale*, natives of South Europe and the Levant. One is a crimson self; the other crimson with black spots. This latter variety, again, much resembles *P. bracteatum*, which has, or should have, a harder constitution, being indigenous to Siberia and the Caucasus. This species has also been called *P. pulcherrimum* by some botanists. There is thus a strong likeness between *P. bracteatum*, *orientale*, and *pulcherrimum*, and all are very handsome plants. It is evident there is some confusion in the nomenclature of Poppies which ought to be set right. Mr. Wolley Dod's statement that *P. umbrosum* is yellow in colour surprises us. The species we offer under this name is an annual, about a foot in height, and is of a crimson-scarlet colour, with a black blotch at the base of each petal.—JAMES CARTER & Co., *High Holborn*.

SHORT NOTES.—FLOWER.

Lychnis dioica with a forked spike, one branch bearing pink the other with pure white blossoms, is sent by Mr. Kingsmill, of Eastcott, who rightly considers it very peculiar as well as very pretty. We have never seen a similar instance before.

Tulipa sylvestris is one of the most graceful of spring flowers; its clear, yellow, delicately cut hanging bells have rather the look of a Fritillary. *Tulipa florentina*, almost identical from a gardening point of view, is of equal value.—G. J.

Diseased garden Anemones (J. R. D.).—The disease is not caused by a scale, but by a parasitic fungus named *Æcidium quadrifidum*. The wild Anemones of our woods are often attacked by an allied species named *Æcidium leucospermum*. The former plant has brown spores; the latter white.—W. G. S.

Hairbell and Bluebell.—If Gerard is referred to, it will be found that *Scilla nutans* is called Hairbell on account of the hares eating the leaves in spring. This I write from recollection. Hairbell and Bluebell are probably *Campanula rotundifolia*. A little investigation on this point from those who have time to look up the question might be useful.—F. M.

Aquilegia glandulosa is undoubtedly the best of all the Columbines, and for the first time in Berkshire I have succeeded in flowering it. It seems to require a stiff, retentive soil, but ours being on the sandstone I have always failed with it. Last autumn I planted it in old, well-decayed cow manure mixed with rich yellow loam, and have had very successful results.—A. BROWN, *Pusey Gardens, Faringdon*.

Helleborus niger maximus.—The other day I questioned a friend who has been in the nursery trade for some thirty years as to the origin of this Hellebore. He said as far as he knew it originated in Aberdeenshire about fifty years ago. Wherever he met with it its origin could be traced to Aberdeen. It was first known to him as *Helleborus niger major*. In his capacity he bought and sold thousands of it yearly. The late Miss Hope, of Edinburgh, sent a special messenger to Aberdeen for it.—R. FARQUHAR, *Fyvie Castle*.

NOTES.

NICOTIANA AFFINIS.—If I were asked to name the best of all the "soft-wooded" plants of recent introduction I should say it is this sweet-scented Tobacco. A plant of it has been in flower with us for the last four months, and the long leafy shoots are now fairly laden with its long-tubed flowers. Seeds sown now and the young plants grown on in a cold frame until October, and then housed along with winter blooming zonal Pelargoniums, will flower from January onwards until June, or even later if required, and by successional sowings I feel assured the plant might be had in bloom all the year round. Although introduced two years ago or more, this plant is not seen so often as it deserves to be, and yet only yesterday the representative of a large seed merchant wrote to make inquiries about it and where its seeds might be procured. Here it seeds but rarely, and cross-fertilisation has not assisted us to a crop in any way. By crossing a large-flowered red variety of *Nicotiana Tabacum* with the pollen of *N. affinis*, however, we have abundance of seeds, and a sowing having been made we are awaiting the results of the experiment with some little curiosity.

THE BRONZE LEAF.—"And what may 'Veronica' mean by the Bronze Leaf?" writes a lady amateur who has a right to be proud of a well-stocked garden. "Can it be *Rodgersia podophylla*? If so, I think Rodger's Foot Leaf seems to be the most appropriate English name." Yes, *Rodgersia podophylla* is, as I take it, the Bronze Leaf by all good right; but everyone to their taste. It was discovered and is named after Commodore Rodgers, who found it in Japan, and it is figured in the *Botanical Magazine* (t. 6691). It is a most remarkable plant, call it what you will, but I am afraid neither Mr. Maries nor Messrs. Veitch were the first to introduce it to our gardens. Grown in deep, rich, peaty earth, in full sunshine, it is one of the very finest of all hardy fine-leaved plants.

MODERN ORCHID SALES.—Now and then we get a genuine Orchid sale. Genuine sales, indeed, are plentiful enough, but what I mean to express is that now and then such genuine and well authenticated plants are offered that they fetch sometimes more than their weight in gold. The late Mr. Dodgson's sale the other day is a case in point, and after hearing a good deal of "bad times" it is a little refreshing to read of the prices *bona-fide* good varieties realised under the hammer. *Cattleya Trianae* Dodgsoni fetched 185 guineas; *Laelia anceps* Dawsoni, 82 guineas; *Cattleya exoniensis*, 56 guineas; a smaller plant, 50 guineas; *Cattleya Trianae* Osmani, 215 guineas; and *Dendrobium Ainsworthi*, 66 guineas; and these, be it noted, only a few of the plants which sold well. The day's sales fetched something like £2000; indeed, as a friend writes, "talk of bad times, why, what are we coming to?" This sale seems to point a moral for all who import Orchids. As we know, in recent times consignments of ordinary varieties have, in many instances, barely paid expenses of collection and carriage. The fact is the country is flooded with weedy Orchids of all kinds, and many amateurs now will only purchase varieties known to be, and what is more guaranteed to be of the first quality. The time of indiscriminate collecting abroad is over; buyers now-a-days seem to wish value for their money. Only the other day Mr. Low told me that he sold Mr. Dodgson a dozen plants for £10 some years ago, and from that nice little lot these two varieties originally came.

HYBRIDISM OR CHANCE SEEDLINGS.—In THE GARDEN for March 31 (p. 296) there is an "American note" on "tree sports"—not a good heading, by-the-by, since some of us like to limit the word "sport" to vegetative or bud vagaries rather than to variations originating from seeds, whether they be of hybrid or cross-bred origin. Mr. Robert Douglas, the veteran nurseryman of Illinois, says that he is sorry to be compelled to confess that all

and rather handsome habit, and will succeed well in either the cool or the warm house, where, on account of their peculiar appearance, they make a special feature. Although mostly adapted for planting out in the conservatory, several of them make elegant specimens under pot cultivation. They are all of very easy culture and grow apace in a mixture of peat, loam, and coarse sand in about equal proportions, with thorough drainage, requiring, as they do, a good supply of water at the roots, and heavy syringings over their foliage during the growing season.

D. ADIANTOIDES (*Sitobium adiantoides*).—This very ornamental species from Tropical America is an exceedingly handsome and free-growing kind, with very thick rhizomes, producing in quantities its splendid bi or tripinnatifid fronds from 3 feet to 4 feet high. These are of a cheerful bright green colour, with obtuse pinnules, and have a very striking appearance on account of the sori being large and prominent. Although it grows fairly well in a cool house, it is grown to perfection and is altogether finer in the stove.

D. ANTHRISCIFOLIA (*Dicksonia anthriscifolia*).—A Tropical American species and a very handsome, strong-growing plant, with fronds 3 feet to 4 feet high, bi or tripinnatifid, of a bright shining green colour, and borne on robust fleshy stalks; the pinnæ are extremely long, sometimes exceeding a foot in length, and the segments of the pinnules are broad and obtuse. Besides the above distinctive characters it is thoroughly evergreen and peculiarly distinct through its prominent and reddish brown sori, which produce a charming effect. Stove.

D. CICUTARIA (*Dicksonia cicutaria*).—This is also a strong growing and handsome Fern provided with underground rhizomes, producing fronds in great abundance; these are tripinnate, almost triangular in shape, and often reach 4 feet in height; they are of a bright light green colour, which they keep until they quite wither away. It is essentially evergreen, and propagates itself very readily when planted out in the border, and although a species native of Tropical America, it grows luxuriantly in a cool or intermediate house, but in any case requires a quantity of water at the roots.

D. DAVALLIOIDES (*Sitobium davallioides*).—A very elegant Australian species, and one of the most graceful of all the genus. The fronds, which are bi or tripinnatifid, are produced in enormous quantities from thick fleshy rhizomes; they grow from 2 feet to 3 feet high and about 15 inches in breadth, with pinnules cuneiform and pinnæ cut into small segments, of a dark, rich green colour, and rather pubescent. It is also an easily managed species. Greenhouse.

D. DAVALLIOIDES YOUNGI.—This highly ornamental species is a native of the New Hebrides, and of very robust habit and vigorous growth. The underground creeping rhizome is thick and fleshy, and produces fronds of noble proportions, attaining the length of 10 feet, and have stout, erect, or sub-erect stalks, quite smooth, rounded on the underside and flattened on the opposite or upper side with a furrow running along their entire length. The leafy portion of the frond is beautifully arching, bi or tripinnate, broadly lanceolate and acuminate; the pinnæ are sessile or subsessile and spreading; the rachis is furrowed on the upper side like the stalks, and the pinnules are of a light, cheerful green and finely cut. The aspect of the whole frond is very airy and graceful. It is a grand Fern for a warm conservatory, and is unsurpassed as an exhibition plant, and as a central subject in grouping where bold and spreading foliage is required. It is also a very rapid grower. Stove.

D. PILOIUSCULA (*Dicksonia punctiloba*).—An elegant and comparatively dwarf growing species from North America, all the more interesting as it is perfectly hardy under this climate. The underground rhizomes are slender and very abundant, and produce in profusion their pretty lanceolate and subtripinnate fronds which seldom exceed 18 inches high, so that it is not only the hardiest, but also the dwarfiest species of the whole

genus; the stems are slightly hairy, the pinnæ very finely divided and of a light green colour; the habit of the plant is rather erect, differing on that point from all the other species in the genus, which are all more or less arching, even the strongest-growing kinds.

DEPARIA MOOREI (*Cionidium* and *Trichocarpa Moorei*).—This evergreen species from New Caledonia is a very conspicuous looking Fern, inasmuch as the sori are situated upon the apex of the veins, which are extended beyond the margins of the fronds; these are from 12 inches to 18 inches high, bipinnatifid and triangular in shape with pinnæ distant, the lower pair being pinnate. It is a compact habited plant of rich dark green colour, not so much cultivated as it deserves, as it has a sin-

INDOOR GARDEN.

THE BIRD PLANT OF MEXICO.

(*HETEROTOMA LOBELIOIDES*.)

THIS is so called on account of the suggestive form of the flower, which fancifully gives the idea of a bird in flight, with its wings meeting above the body. It is very pretty and curious, though not very showy. The corolla is split to the base on the side nearest the stem, and is prolonged below into a large spur, which secretes at the bottom a large quantity of nectar, alluring, no doubt, to insects, which perform at the same time the operation of pollination. This spur is of crimson-lake colour, and the upper part of the

Flowering spray of *Heterotoma lobelioides* (colour, crimson and yellow). Drawn from a plant at Munstead.

gular and unique appearance produced by the sori standing out beyond the margins of the fronds, like if they were supported on little thread-like footstalks, yet it is a very manageable plant of good growth provided that it be potted in good fibrous peat and silver sand, and has a good supply of water at the roots, but it dislikes syringing overhead. Stove.

D. PROLIFERA.—This species, from the Sandwich Islands, forms with the one just described the entire genus *Deparia*. Like the preceding one, it is a most distinct and handsome species, and will thrive equally well under a similar treatment. The fronds, which grow from 2 feet to 3 feet high, and are somewhat triangular in shape, rise from a stout creeping rhizome; they are bipinnatifid and light green in colour, and occasionally bear young plants on their points, hence the specific name. The sori are marginal and situated on the extremities of the veins, as in *D. Moorei*. Special attention must be given to the drainage, which should not be allowed to be deficient in any way, as it is the principal cause of failure in the cultivation of *Deparias*. Stove.

PELLÆA. The corolla is canary-yellow. The raceme bears from twelve to sixteen flowers, and they measure from the anthers or head of the bird to the tip of the spur or tail rather more than an inch and a half. Good specimens are flowering in the Cambridge Botanic Garden, where they usually grow about 2 feet high; in growth they are erect, and every stem comes from the base bearing rather handsome cordate-ovate leaves with long points. These plants were kindly presented by Mrs. K. L. Davidson, of Salisbury, and have been grown chiefly in a warm greenhouse, which appears to suit their requirements. They have been potted on into 6-inch pots in a mixture of about half peat and loam, and as the pots become well filled with roots, a saucer for water was placed under each, which evidently has been of great advantage. It appears likely that good flowering stems will grow only from the base, and therefore it would be desirable to cut away old stems for the purpose of encouraging strong growth from below. If the plants are made to branch much, it is probable that the individual inflorescences will be small. Cuttings which have been put in appear likely to

strike without difficulty. Insects have not yet given any trouble, but a tiny white fly (*Aleyrodes*) has evidently a great liking for the plant, though it appears to do very little or no harm.

R. IRWIN LYNCH.

[Our illustration was drawn from a specimen from Miss Jekyll's garden at Munstead, but it unfortunately was not a well developed one. The flowers are shown to be nodding forward about a quarter of a circle from the true position. A few days ago Mr. Lynch sent us some extremely fine specimen long shoots terminated by a numerous raceme of large and highly coloured blossoms. Grown as it is at Cambridge, it must be a really pretty plant. It is at present a very uncommon plant, though it was first introduced in 1861.]

WINTER PELARGONIUMS.

OF all greenhouse plants *Pelargoniums* I think the most useful, especially the zonal section, both single and double, as by a certain course of treatment they may be had in bloom quite nine months out of the twelve, and many sorts even the whole year round. To get them to flower during the autumn and winter, when they are of the most value, it is necessary to prepare them specially, and the way to do this is to stand or rather plunge them out doors in some exposed spot where they can have the full influence of the sun, as the great point is to harden the growth, for unless the shoots become well consolidated and ripened they never bloom in the free manner they ought.

THE BEST plants for winter flowering are those struck early in spring, which should now be shifted on into 6-inch or 8-inch pots, according to the size and strength of the plants, but as a general rule the less root room they have the better they do, for if they want help that can always be given at any time by watering with liquid manure. The soil most suitable for zonal *Pelargoniums* is a fibry loam, which may be improved by adding just a sprinkling of soot, and incorporating the same with it, as the soot not only acts as a fertiliser, but assists greatly in keeping out worms, and adds to the colour both of blossoms and leaves, to the latter of which it imparts a deep healthy green. Towards autumn, just before taking the plants in, it is a good plan to keep them a little dry that they may have a short rest, and it will be found that directly they goulder glass they will begin to send up their blooms. To have these at their best and prevent damping the plants should be stood on shelves or other positions where they can get plenty of light and air, and a temperature ranging between 45° and 55°, which degree of heat is requisite to keep them steadily moving. Although most varieties will flower during the entire winter, there are some better adapted for that season than others. The best winter bloomers are *Vesuvius*, *Jessica*, and *Ianthe* in the single class, and *F. V. Raspail* and *Wonderful* in the double. Not only do zonal *Pelargoniums* required for winter bloom do best when grown outdoors, but those required for the embellishment of greenhouses during summer are greatly improved by similar treatment, but they should not be placed out till they have been prepared for the change, as any sudden transition from the protection and shelter of glass to the open is sure to injure the leaves, which under such circumstances become scorched and discoloured.

SHOW AND FANCY KINDS, though perhaps not so serviceable as the zonals, are very beautiful, and make a grand display at this season, while some may be had in soon after Christmas. The best for that early period are the old *Alba multiflora*, *Alma*, and some of the new varieties, such as *Crimson King* and *Duchess of Edinburgh*, both of which are very fine. To have any of these good early, cuttings must be struck at once, and old plants intended to be kept cut back, that they may break again and become refurnished below. The later flowering sorts also require the same treatment, but before cutting them back it is necessary to have them well ripened. The ripening may easily be brought about by standing the

plants in the full sun and keeping them rather short of water at the roots, which at once lessens the flow of sap and causes a general hardening of the shoots. Many lay the plants down on their sides, but that way of bringing about ripeness is a very objectionable one, it being much too sudden, as the bark becomes contracted and the tissues dried up instead of the parts being made hard and woody, which is the point to be aimed at. In cutting back, *Pelargoniums* they should be shortened to within three or four buds at the base of each shoot, but if extra large plants are required they may be left longer, so as to form a frame, as it were, to furnish up with young growths. The proper time to shake the plants out is as soon as the buds have started, when the roots should be trimmed in a bit and the plants re-potted in smaller pots, giving them the same kind of soil as that advised for the zonals. The potting complete, the best place for the plants is in a pit or frame, where they can be kept somewhat close and shaded for a week or so to give them a fair chance of making a start. What assists them very much in this is a syringing overhead both morning and evening, which, by keeping the atmosphere moist, is much in their favour. As soon as fresh growth commences the plants should have full light and plenty of air to induce the young shoots to become short-jointed, sturdy, and strong. Although the show and fancy kinds do well up to a certain time in pits, they will not winter there without

SPOT COMING ON THE LEAVES, a disfigurement generally regarded as a disease, but it is not so, and only occurs through the action of damp and a low, unsuitable temperature. The most suitable place to winter the plants is on light, airy shelves up near the glass, where, if not over-watered, they are sure to remain healthy and strong. The fancy varieties, being a little more tender than the show sorts, require a little more heat to do them well, and for these the temperature should never be allowed to fall much below 45°. Excepting aphides, which are very troublesome, this latter class are not subject to insects, but to keep them clear from green fly requires much vigilant watching and frequent fumigation by Tobacco of the house they are in, which is the safest and best remedy against this pest, and kills it quickly without harming the plants. D.

CULTURE OF EPACRISES.

AMONGST greenhouse plants now in cultivation none are more serviceable than *Epacris*, as not only are they of great use for decorative purposes, but they are of much value in a cut state, their long, slender shoots clothed with gay blossoms being just the thing for vases, where, if kept supplied with fresh water and not subjected to a dry heat by being placed too near a fire, they last a long time in perfection. *Epacris*, being hard-wooded subjects, are generally supposed to be difficult to grow, but in reality they are not so; on the contrary, they may be managed much more easily than *Heaths*, as they will endure a confined atmosphere better, and do not object to a certain amount of artificial heat, of which most *Heaths* are exceedingly impatient, and soon show signs of the injurious effect which it has on them by becoming mildewed and falling into a bad state of health.

EPACRISES ARE NOT DIFFICULT TO GROW, but they are to propagate; as this, however, is carried out extensively by professional and skilled hands in nurseries, and as plants may be bought very cheap, it is hardly worth while attempting to strike any; indeed the attempt to do so would be more than likely to end in failure. Those who would like to begin their cultivation should purchase plants at once; by getting them now when in flower, choice may be made of the sorts. When the blossoms have faded, cut back the shoots in order to induce the plants to break again below and form a number of young ones at their base; it is on these young shoots that the flowers of the following year will be borne. The extent to which they should be pruned depends on their

strength, but in a general way about a couple of inches of the old wood is quite enough to leave, and to insure this portion breaking well, it is always advisable to stand the plants in a house where they can be kept tolerably close and have a warm, moist atmosphere just to give them a start. A slight syringing now and then on the mornings and evenings of bright, sunny days will help this matter materially, and as soon as they are fairly on the move it will be high time for potting all that require a shift. The only

SOIL that suits *Epacris* is peat, which should be of as fibry a nature as it is possible to get it, and when chopped up tolerably fine have a heavy sprinkling of sharp silver sand cast over it and the whole thoroughly mixed together. In potting it is important to have nice clean pots, and to see that they are well drained by having an inch or so of finely broken crocks in the bottom, over which should be strewn a little dry Moss to prevent the interstices becoming filled up with the soil. The pots prepared in this way, all will be ready for shifting the plants, and in doing this it is very necessary to ram the peat hard in around the old ball, so as to make it as solid as possible, otherwise the water when given will pass through and leave that part unmoistened, and the plants will languish and die. *Epacris* make their growth best under glass, but when that is complete they should be stood in some shady position outdoors, where, exposed to the air and night dews, they keep more healthy and are enabled to ripen their wood. D.

THE BEST CASSIAS.

ALTHOUGH the species of this genus number several hundreds, those of a sufficiently ornamental character to merit a place in the garden are but few. As seen growing under natural conditions, many of the *Cassias* are strikingly attractive, especially those of an arborescent character, the general appearance of which is said to closely resemble that of our own *Laburnum*. The difficulty, however, of reproducing those conditions which are essential to many of these and other beautiful tropical trees makes it almost impossible to cultivate them with anything like success in this country. We have, however, about half-a-dozen useful *Cassias*, speaking horticulturally, and in addition to these there are several species to be met with in botanical collections. Of the ornamental kinds, the annexed woodcut represents one of the best, viz.:—

C. FLORIBUNDA.—This is a handsome yellow flowered species, and one which thrives in a warm greenhouse or stove where it yields an abundance of flowers almost all the year round. It forms a compact shrub, grows very freely, and is easy to manage, being at home in any open soil, and likewise suffering very little from the attacks of insects.

C. CORYMBOSA is a handsome greenhouse species, of which a description and cultural information were given in Vol. XXI. of THE GARDEN. It may be used for sub-tropical bedding in the warmer parts of the country, and if planted in good soil in spring, it forms a good sized shrub in a short time and flowers very freely.

C. ALATA may be treated in the same way, and is quite as handsome as the last mentioned. *C. Sophora* is a good plant for training along rafters or pillars, as it is very accommodating, growing freely and flowering literally during the summer months. *C. florida* is another shrubby species, which bears large panicles of deep yellow flowers.

C. MARYLANDICA is perhaps the best known of the *Cassias*, being often used in the herbaceous border. It is a very pretty perennial, growing to a height of from 3 feet to 4 feet, and thriving well in any garden soil. This species is largely cultivated in North America for its leaves, which form one of the *Sennas* of commerce; it is sometimes called wild *Senna*. *C. Fistula*, the Pudding-pipe tree, *C. angustifolia*, *C. angustiloba*, and *C. Alexandrina* are the most important of the species, possessing valuable medicinal properties. B.

FLORISTS AND THEIR FLOWERS. TO THE EDITOR OF THE GARDEN.

SIR,—If it were true that the florist is responsible for the displacement or neglect of the garden Auricula, "J. M.'s" indignation with him would, no doubt, be abundantly justified, but I do not see that the charge is sustainable. The old florists, whose work is being continued now, were, as is well known, toilers in the town, and it scarcely fell within their scope either to promote or to hinder the cultivation of purely garden flowers. They did the work that lay to their hands, and beautiful work most of us think it is. Fashion is mainly answerable for the neglect of the Auricula, as it has been for the temporary obscurity of hardy flowers generally, and of many another good thing besides. It would probably be much nearer the truth to say that we owe it to the never-ceasing devotion of the florist to this flower that the Auricula has been kept before us in any shape. "J. M." appeared to be under

(p. 442), "is naturally a rock plant, likes a dry soil, and is easily managed in pots." We only seek to give it in this way essential conditions which we cannot guarantee it in the open ground. But if the florist's Auricula requires this partial protection in our over-moist climate, it amply compensates us by its strength in another direction. It defies the smoke fiend, before which so many other beautiful hardy plants succumb. With those other favourites of the florist, the Carnation and Picotee, it is, for this reason as well as for its beauty, of priceless value to us townsmen. In regard to form in the florist's Auricula, which "J. M." says is condemned by the educated artist, who is best fitted to judge of the matter, I should wholly decline to take the judgment of the artist alone as to the value or quality of the work of the gardener and the florist. The artist is a poet, and looks at flowers from the poetical standpoint. He would give us little else but the Dog Roses and the Daisies and the other simple types of flowers

flower can only render them his most hearty well-wishers.—M. R.

— "J. M." blames florists for not producing garden Auriculas; if he will come to Brockhurst I will show him Auriculas grown outdoors as well as indoors, on the rockeries and beds as well as in frames, but I do not risk valuable sorts worth a guinea apiece, to the chances of slugs and weather when I can conveniently protect them. The Auricula is hardy if anyone likes to plant it out, and a great many Auriculas are planted out. He then states that the Primrose is not grown as it deserves; but if he will come here, I will show him as fine Primroses as he ever saw, and these by hundreds. The Primrose has been as carefully fostered by me as has the Auricula, and in the course of six years of florist culture it has been immensely improved, and not only in my garden, but the whole district has followed suit, and beautiful Primroses abound everywhere around us. The florist aims at the production of perfect flowers, and the rules by which their qualities are judged are well settled and acted upon. They are the outcome of a century of florist work, and I believe that in every case it can be shown that they are based upon true principles of floral beauty and perfection. This applies to the Carnation, Dahlia, Tulip, Pink, and Auricula. Each has its model before it, and it is the pride and pleasure of the florist thus to strive for perfection of form. I think it cannot be denied that this is a wholesome hobby, and when we bear in mind that working men for the most part constitute the florists in any society, and that they have not long purses and large gardens, it is scarcely wise to give them nicknames, and to flout their honest endeavours after beauty and perfection as "J. M." does. If he wants to establish a society to grow shapeless common flowers for anybody's garden, let him set to work and give the example, and we will come to his show at South Kensington and see how it looks. It is my pleasure and privilege to know a great many florists who are hard-handed working men, and I can testify to the good influence this growing of florists' flowers has upon them. I only wish there were more such societies as the National Auricula Society in our busy centres of industry, and that more gentlemen than the few there are associated with working men in a pursuit of common interest and of an elevating tendency.—WM. BROCKBANK, *Brockhurst, Didsbury.*

Flower branch of Cassia floribunda (much reduced).

the impression that the "pip men" were regardless of the beauty of the garden Primrose, but I was able to show him that the Primrose had no more earnest and practical friends than the very "pip men" he derides. He is, I think, equally unjust to them in the case of the Auricula as he was in that of the Primrose. But even if we assume that the florists are blameable in not having taken up the culture of the garden Auricula, that does not, as "J. M." argues, prove that the work which they have done in their own line is contemptible. He may rightly or wrongly reproach them for what he considers their neglect in one direction, but that gives him no title to disparage what they have actually accomplished in another. In the matter of hardiness, I venture to think that the garden Auricula is not so universally hardy—if by "hardy" we mean the capacity of thriving under all influences—nor the show Auricula so tender as "J. M." alleges. I know the way Auriculas can be grown in the country. I had some last year and the year before with root-stocks, as "J. M." describes, like Turnips, but this did not avail them in my inferior climate against the excessive wet of the spring, which rotted nearly all of them. Of my show sorts, on the other hand, brought last summer and "coddled," as "J. M." would say, in pots and cold frames, I have not had to lament the loss of a single plant. The Auricula, as Mr. Brockbank usefully points out

—beautiful indeed in their simplicity. This, it may be allowed, might please the aesthetic sense of the artist, but it cannot be pretended that it would satisfy the longings of humanity. The artist and the florist has each his vocation, and the more they get to know of each other's work, the more likely they will be to understand and appreciate instead of misconceiving and undervaluing it. In connection with the question of forms and colours, "J. M." finally asks, "What is a green edged Auricula but a monstrosity?" I answer that a monstrosity is something ugly and hideous. But a good green-edged Auricula is beautiful in its shape, beautiful in each separate feature, and exquisitely harmonious in its colours. I have no pretension to call myself a florist, but even to my uneducated eye it seems like a want of appreciation, almost parallel to that of colour blindness, which can lead to the describing of a flower like Colonel Taylor or Lancashire Hero as "a monstrosity."

As to the advancement of our knowledge of the garden Auricula, which "J. M." has so much at heart, the florists are pretty well occupied with their work as it is, and the accident of their location would preclude many of them undertaking much in the direction "J. M." indicates. But if "J. M." can do anything to improve or extend the cultivation of the garden Auricula, he may rely upon it that the affection of the florists for this

I am sorry to trespass further on your valuable space by noticing "Peregrine's" lucubrations on this subject in THE GARDEN (p. 445), but I fancy I see my way to eliciting a wholly new and original piece of information, which will doubtless be of much interest to many of your readers. Speaking of what he calls "popular races of flowers" and the improvement which has been effected in them, he says, "it was only when the work was taken out of their (the florists) hands and conducted on broader lines that any great strides in improvement were made." I pass over the rather contradictory statement in the preceding paragraph when he states that "florists have had but little or no hand in such work." What was never in our hands can hardly with propriety be said to be "taken out of them." But what I demand to know is this: What are the flowers which have been thus taken out of the florists' hands, and have made great strides in improvement in consequence? This is really an important question, for if "Peregrine" can sustain his statement, he goes far, indeed, to convict florists of being the worst enemies of floriculture. This is, to say the least, so novel a position, that he must expect that we shall demand that the proof shall be ample. Nothing less will suffice than a list of the plants which were once in the florists' hands and were taken out of them, and great strides in improvement made in consequence. When one reflects on the work which has been effected by florists, it seems almost ludicrous to be obliged to defend them against such charges as "Peregrine" brings. He evidently knows nothing whatever about florist's flowers. But surely this is no justification for assisting those who do. As well might

I denounce a pigeon fancier for making much of certain points and qualities of which I know nothing about; or a print collector for setting great store on some rare copy "before letters." "Peregrine" may care as little for the florist's pursuit as I do for those mentioned; but I certainly do not feel called upon to express my contempt for pigeon fanciers or print connoisseurs, or to presume to tell them the rules by which they proceeded were narrow and contracted. Yet this is the sort of criticism which "Peregrine" has no hesitation in using towards florists, for the simple reason that he knows nothing and cares nothing about their pursuit. Well, we can put up with his censure as best we may. I doubt that our florist will see the error of his ways in consequence of such criticism. In the meantime we await with interest such a justification of his charges as I have indicated.—FREDERICK TYMONS, *Cloghan, Co. Dublin.*

—Mr. Tymons (p. 417) does not appear quite to understand the objections which the lovers of flowers in their natural state have to the productions of the florist. The first objection is the tendency to produce varieties of hardy flowers which will not stand the rough usage of open ground cultivation. This is an objection which only affects people who put their trust in named varieties, as anyone can with a little care and selection raise good hardy varieties of all hardy florists' flowers which can be cultivated in the open border without protection. The secret objection is that the florist's ideal is a totally wrong one, and that as regards form what he aims at is ugliness, not beauty; degradation, not improvement. Nature is the standard of all beauty; art must go to Nature for her canvas; not promiscuous Nature, but Nature in her highest and most perfect expressions. Even ornamental or decorative forms are good or bad as they approach or recede from natural forms. When we begin to attempt improvements on Nature we must keep to her lines and style, or we go utterly wrong. We may enlarge her flowers, vary their colour or markings, or even double them, so long as we retain delicate and subtle curvature of outline and marking, play of light and shade, and harmony and grace of form. The most legitimate double flowers are those of the Aster, or composite family, for these are not truly double, and we only do with them what Nature does in the Dandelion. Additional petals may be an improvement, as in the Carnations and Pinks. Stamens and pistils may even become petals, as in the Rose, so long as grace, variety, and harmony of form are not interfered with. When, however, the beautiful forms of Nature are cast aside, and the florist dictates that a Tulip must consist, not of six spoon-shaped divisions of beautiful form such as Nature makes, but of six badly-formed petals forming a cup with a margin as nearly straight as possible. That a Carnation or Picotee must have all its petals alike, and all marked alike; that a Pansy must be flat, and a perfect circle, so that the two upper petals are almost totally hidden; and that an Auricula must present a series of rigidly concentric circles; then every one who appreciates the true beauty of flower-form must object to this substitution of designs borrowed from the draughtsmen's room of a machine factory for those subtle natural outlines which require some years of systematic study of drawing before they can be transferred to paper correctly. That kind of improvement is simply attempting to bring down Nature to the level of wholly untrained perceptions of form instead of endeavouring to train up the perceptions so as to be capable of appreciating and enjoying the beauty of Nature's handiwork. Take, for instance, Mr. Tymon's favourite flower, the Auricula; the increased size of the flower; the lasting of the first flowers until the whole truss is expanded; the varied and distinct colours are all commendable, but the circular outlines are the reverse of that. The circle is the ugliest of curves; it has no variety, and curved forms only become beautiful as they recede from circles or parts of circles. Take a single Auricula bloom simply as a decorative

rosette in colour. The natural form of petal is very beautiful, especially when the indenture in the centre of the tip of each petal is distinctly marked; the attempt to improve such a form is to spoil it. To treat such a simple rosette in four distinct colours a decorative artist might allow the centre to be a circle, but he would certainly abolish the circular paste and make that project with an obtuse point into the base of each petal. Then the best treatment for the margin or lacing would be to start almost at the paste with a fine line, increasing in thickness towards the tip of the petal, and dipping into the petal with a neatly outlined widening just at the indenture in the centre. The outlines between the colours would by such a treatment be harmonious and advantageous to the display of distinctly contrasted colours. Run-back seedlings from laced Polyanthus often show a tendency to that form of lacing, showing that such a form could be easily perfected. J. D.

LEAVES FROM THE SOUTHERN ALPS.

COMPOSITE PLANTS are very largely represented in the Tasmanian flora—Eurybias or Asters, Helichrysums, Senecios, Brachycomes, and many other genera comprising a large number of species represent this class. I shall have something to say about the Eurybias when I come to discuss my friends on Mount Wellington. In the Domain the composites are chiefly represented by three or four forms—two Helichrysums, a very pretty Australian Daisy (Brachycome), and the Leptorhynchus squamatus, an unattractive herb with a number of yellow heads like Pansy pips. Both Helichrysums are yellow and very pretty. First and most attractive is the little yellow Immortelle, *H. apiculatum*, grown in England, and, I believe, largely used where Evergreens are in demand. The leaves, like those of many of the Helichrysums and Gnaphaliums, are covered with a dense coating of silky wool, and the corymbs of flowers rise well up and are of a very bright, deep canary yellow. *H. scorpioides* is another Domain variety, larger and looser in habit than the one just mentioned, but a handsome flower of a deep corn yellow. I may go out of my way to mention here a fine Helichrysium which I found at New Norfolk, a Hop-growing settlement about forty miles up the Derwent. It is *H. semipapposum*, a singularly handsome plant if somewhat lank and loose in habit. It has a rigid stem 1 foot to 3 feet high, clothed its whole height with long linear leaves. The great beauty of the plant is its large clusters of very small brilliant yellow heads, as nearly approaching the colour of bright gold as any plant outside the Lichen family does. This is a Helichrysium which I think might become a very fine garden subject under cultivation, especially if a dwarf habit could only be induced, for I must acknowledge that, beautiful as the golden flowers are, its gawky, sprawling habit detracts seriously from its merits as a garden plant. The specimen of this plant that I have before me now is just as fresh and rich in the colour as when plucked, and the same may be said of the apiculatum species. I afterwards fell in with *H. semipapposum* in Victoria.

YELLOW seems to preponderate amongst the Domain wild flowers, for of a very bright Buttercup colour is the little creeping *Goodenia hederacea*, a very prostrate spatulate-leaved plant that would look neat and bright amongst low-growing rock plants. Very attractive, too, is the low-growing *Pimelea humilis*, the small, though not the smallest, representative of a Tasmanian family of seventeen. I shall have occasion to notice some of the shrubby members of this family in dealing with the Mount Wellington flora. *Pimelea humilis* grows in small clumps from a very woody root to the height of 3 inches or 4 inches; my herbarium specimen, root and all, measures about 6 inches. Each plant has several stems clothed their entire length with ovate leaves somewhat silky in texture. Each stem bears one or more tassels of florets mounted on a pretty whorl of bractal leaves. The small funnel-shaped florets are of a creamy white, and are gathered

together in pretty thread-looking tassels, which are, however, not pendent, but upright. A very curious order of Australian plants, the Stylidiaceæ, is represented here by the interesting

STYLIDIUM GRAMINIFOLIUM, or Grass-leaved Trigger plant. It takes its generic name from the curious arrangement of the stamens and style, which join into a column, bent back with its top resting on the lip of the corolla. When the column is touched it springs back suddenly to the other side of the flower, and by the violence of the movement scatters the pollen and secures fertilisation. The flower no doubt is—at any rate it ought to be—in cultivation in English gardens. The Tasmanian waysides and pastures are in some places red with its slender spikes of bloom. Amongst hundreds, possibly thousands, of plants in flower I came upon one white specimen, which I dug up carefully and packed away with other specimens to be sent home. Most people know something of the

LITTLE GODDESS OF THE WOODS, the pretty blue Dianella, which at the time of my visit was somewhat past its best, the blue seed berry being formed in most cases. Yet it is of such frequent occurrence, that I was able to come upon one here and there in a state of good preservation. It has long, narrow leaves, and the panicles of flowers rise high, sometimes 2 feet or 3 feet above the ground, the stem dividing and redividing into many rigid branches, which terminate in numerous slender wiry filaments on which tremble the little azure disks, set off in the centre with rich golden stamen threads and brown velvet anthers. The species are far from distinctly separated, so that I do not venture to give a name to the specimen which I secured. The Dianella is the very ideal of a wild flower, not perhaps very effective at a general glance, but one that grows upon you the nearer you look at it, like the pink-spotted blossoms of some of the Saxifrages. Under the lens it is extremely beautiful, for only then is the full beauty of the interior of the flower fully appreciated. The last Domain plants I shall notice are two not very attractive in themselves, but having points of interest, nevertheless. The one is *Acæna ovina* and the other is *Xerotes longifolia*. The *Acæna ovina* is a near relative of our *Sanguisorba*, which is native also of Tasmania and Australia. *A. ovina* has some of the *Potentilla* foliage with very tall flower-stems, surmounted by a tenacious little ball or burr like its New Zealand congener. The adhesive calices of this *Acæna* are said to be very troublesome, and the name would indicate that it is more particularly a wool pest. The *Xerotes* is a peculiar Australian genus of the Rush family, in appearance something like a Sedge, with much branched panicles of flowers, the greenish prickly florets being arranged along the scape in little balls. A corner of the Domain facing the river Derwent is occupied by

GOVERNMENT HOUSE AND GROUNDS and by the Royal Society's Gardens. Government House is a somewhat ornate and very handsome building of sandstone; the stone for which has evidently been taken from quarries in the Domain, one of which is filled with water, and devoted to the cultivation of Water Lilies and frogs. The other has been put to no purpose, and is now overgrown with a growth of young Wattles and various native and British weeds that like a ledge of sandstone to hang over. In front of the governor's residence, and, indeed, forming a continuation of the grounds, are the Royal Society's Gardens. They occupy a piece of undulating ground sloping to the Derwent and command a large number of very lovely views of this very beautiful river, and of the blue Eucalyptus-clad hills that rise up on all sides round Hobart and stretch away in gentle rounded lines, growing bluer and bluer till they vanish in the distance. From some seats glimpses of the town and shipping may be seen; from others little pieces of the river between the trees with the pleasant little headlands and receding bays on the other side towards Kangaroo Point, forming a very pretty background. The gardens are evidently

under very careful and intelligent management, and I must here acknowledge the courtesy of Mr. Abbott, director of the gardens, in showing me over them, and the valuable assistance he rendered me in identifying the flowering plants that I collected. Trees, shrubs, and flowers from all lands are well represented in

THE GARDENS OF THE ROYAL SOCIETY. If I have any fault to find with them, it is that the flora of Tasmania is very inadequately represented. There are good collections of New Zealand and Australian shrubs. Amongst the former were specimens of *Metrosideros diffusa* (in flower), *Pittosporum* of kinds, *Brachyglottis*, and *Entelea*. One large bed was devoted to Palms, amongst which I observed large plants of *Areca*, *Seafortia*, *Chamærops*, *Corypha*, and *Cycas revoluta*. The various Pine families were well represented, and it was very pleasant to see magnificent large specimens of conifers, familiar enough to me in a smaller state, and to make acquaintance with some absolutely new to me. Norfolk Island Pines (*Araucaria excelsa*) were well represented by fine, straight, well-grown trees rising like spires. The Maiden-hair tree (*Salisburia adiantifolia*) of Japan was also there, and the glaucous-leaved *Amboyna* Pine of Borneo (*Dammara orientalis*), the Moreton Bay Pine (*Araucaria Cooperi*), *Cedrus Deodara* and *atlantica*, various *Piceas*, and *Pinus* of many kinds. Strange to say, both in Tasmania and Australia there are few specimens to be seen of the *Araucaria imbricata*, a fact which, though I mentioned it to various horticulturists, I did not have satisfactorily explained. In Victoria—particularly in the Melbourne Fitzroy Gardens—there are magnificent specimens of the Queensland *Araucaria Bidwilli*, a tree which when well grown is quite as beautiful as *A. imbricata*, though its beauty is of a different kind, its habit being looser and less formal; but I do not remember seeing a single *Araucaria imbricata*, though, no doubt, trees are to be met with here and there. Those to whom I remarked the absence of this tree were of opinion that it could not withstand the heat of Victoria, but this will not explain the rarity of its occurrence round Hobart. One particularly interesting feature about these gardens is a long and high brick wall, one side of which is covered with a large selection of well-grown

CLIMBERS. The height of this wall might be about 15 feet, and in most cases the climbers reached the coping. All of them were not in flower at the time of my visit, but there can hardly be a spring, summer, or autumn month in which something is not in flower. There were the two varieties of *Bougainvillea* bearing a few racemes of mauve blossoms. *Ipomœa Leari* was there, a magnificent plant, but not in flower. Afterwards I saw it richly laden with bloom on Melbourne verandahs. The Clematises were represented by *C. Flammula*, with small dusky blooms; *C. leptophylla*, a North American species with a much cut leaf, and various hybrid varieties. *Passifloras* by *P. peltata*, *P. elegans*, *P. Ballotti*, and others. *Tacsonias* were numerous, and included *Van Volxemi*, *Mortii*, and a very fine example of *exoniensis*. *Tecomas* were also in good variety, but the remembrance of them pales beside the recollection of the *Tecoma splendour* which I afterwards saw in Melbourne. A very fine plant of the Canadian *Aristolochia sempervirens* was covered with its amber cornucopias. *Rhynchospermum jasmminoides* was very large and loaded with fine flowers. A very interesting plant on this wall was the Kumquat (*Citrus japonica*), bearing at the same time fruit and flower. The small Citrons were about the size of a Spanish nut and of various degrees of ripeness. The flowers were very pure and very substantial—not unlike a single pip of *Stephanotis*, and very strongly perfumed. A large sunny slope facing the Derwent is devoted to a collection of

HERBACEOUS PLANTS and bulbs, natives of all countries. Amongst other plants I observed—taking bulbs and herbaceous plants indiscriminately—*Brodiaea coccinea*, *Calochortus Somisti*, *Ixia alba*, which I remarked for the great purity of its white; *Cooperia pedunculata*, with a very

lustrous white flower of the shape and size of a Sparaxis; *Oxalis esculenta*, its leaf rising about 12 inches from the ground and divided to the stalk, the divisions forming a sort of dome or umbrella, and the pink flowers rising in large clusters well above the leaves. There was a good collection of *Campanulas*, some good, but some weedy, including *C. glomerata*, *C. sarmatica*, pale lavender; *C. alliariaefolia*, white flowers with edge of petal scalloped; *C. pyramidalis*, *C. Speculum*, *C. Groszeki*, *C. grandiflora*, *C. grandis*, and a good many others; *Callirhoe macrohiza*, the pretty blush flowers having five fringed petals; *Silene*, *Saxifrage*, *Coronilla iberica*, a fine showy yellow rock plant; *Minuria Candollei*, a pretty Australian composite; *Geum coccineum*, *Erigeron glabellum*, with Aster-like flowers of a pale lilac; *Phyteuma comosum*, various herbaceous *Veronicas* of dwarf or medium height—*V. incana*, *orientalis*, *argentea*, *amethystina*, and others, *Omphalodes verna*, *Achillea Filipendula*, *Enothera macrocarpa*, *Papaver bracteatum*, and *Papaver pilosum* with salmon-coloured petals. Besides these and many other plants, beautiful in themselves or interesting from the associations connected with them, the gardens were a blaze of colour from the various annuals and florists' flowers that grew in profusion in all directions. Of these I may mention only the wonderful specimens of ivy-leaved *Gerauiums*, which seemed to grow without training into fine large pyramids covered with bloom. There is a clearness and freshness in the blooms of *Pelargoniums* grown in the open in Tasmania which we here could only hope to have under glass. Altogether, what with the delightful weather, the brilliancy of the flowers, and the depth, variety, and freshness of the greenery, the Hobart Gardens were as fair a bit of garden scenery as I can ever hope to see. Though I afterwards found the Melbourne Gardens grander and more instructive, I cannot say that they gave me so much pleasure.

PAKEHA.

TREES AND SHRUBS.

FORESTRY FOR JUNE.

TOWARDS the end of the month coniferous seeds will commence to germinate. The beds should be kept carefully weeded, and in the case of tender species a little protection should be afforded if found necessary. Gather Elm seeds, and have them sown at once before the coating on the seed begins to harden. Young seedling *Wellingtonias* are sometimes apt to be cut over by slugs and worms; a slight dressing of salt, powdered lime, or both will assist in getting rid of these pests. Look over all young stock and disbud, cut back, or remove all rival leaders at the top. *Rhododendrons* as they finish flowering should have their dead flower-trusses cut off, which not only gives the plants a tidy appearance, but is better for their health. Standard plants that have been grafted should be examined, and any suckers that may appear at the roots below the graft should be pinched off. Prune young Oaks and other deciduous trees by removing all superfluous leaders, and cutting back any strong rambling branches in order to form a well-balanced, uniform top. Stem-prune by cutting off all side branches for a distance of one-third the height of the tree. By this means the foundation will be laid for the formation of clean, sound, valuable timber. Trees that have been managed according to the above rule in early life seldom require much attention in the way of pruning after they attain a medium size.

LARGE ORNAMENTAL TREES on the lawn or in the park that have had any branches broken off by wind should have the wounds dressed by paring off all splintered wood in order to render the surface hard and clean, and so prevent decay by the lodgment of water. Large branches and limbs that run the risk of being torn off by storm and wind should be cut back in order to lighten them and lessen the risk of accident. Holes in the trunks of trees where branches have been torn off are open receptacles for insects to

lodge and breed; these should be cleaned out and all dead wood pared off, and the places washed out with a strong mixture of lime and water, which will not only banish the insects, but also destroy their eggs, and kill all cryptogamic or other vegetable growths, and assist in the formation of clean, healthy bark. Old trees that are showing marks of decay should be thoroughly examined, and the forester should take a note in writing of the apparent cause of failure, which will be of use as a reference when he is about to apply a remedy. Towards the end of this month young plantations should be examined, and all young trees that are being choked by grass or weeds should have them cut away, care being taken not to break off the terminal buds on the leaders of the young plants. See that all standard trees and shrubs on the lawn are properly protected from the inroads of cattle. Young shrubberies and ornamental plantations will be benefited by having the surface soil stirred with a hoe, even in places where no weeds are appearing, yet the plants will thrive much better after the operation. Oak barking will soon be drawing to a close in the south of England and Ireland, but in the north it is at its height. In felling large timber care should be taken not to allow the falling tree to crash into its neighbour, as serious damage is often done in that way which takes a series of years to repair, and indeed sometimes never can be repaired. In the case of coppice wood have the stoles dressed in such a way that water cannot lodge on the top to cause rot. Take advantage of fine, dry weather to have wood and iron fences painted where necessary. Carts, wheelbarrows, &c., should get a coat of paint in dry weather, which will not only assist in preserving the wood, but also give them a clean, tidy appearance. Rid every place of weeds before they begin to shed their seed, bearing always in mind that cleanliness and neatness constitute one of the principal points of good forestry.

J. B. WEBSTER.

Eucryphia pinnatifolia.—In the garden of Mrs. Hammersley, next door to Mr. Veitch's, at Coombe Wood, are three immense plants of this splendid shrub. They are growing in sandy peat with a gravelly subsoil; the highest is more than 9 feet. In autumn they are smothered with flowers. This garden once formed part of Mr. Veitch's nursery and is full of specimen plants, including the largest *Bambusa Metake* I have ever seen.—FRANK MILES.

New plantations.—When the formation of these is contemplated the ground should be fenced and all wet places properly drained, in order to give it time to drip and cleanse itself before being planted. In the case of flat peat bog it should be drained several years before planting operations are commenced, and the first or preliminary step to be taken is to lay off the main arterial drains in such a way, if possible, that they will answer the double purpose of a fence and outlet for the principal flow of water. The next step to be taken is the formation of roads. These should not be too broad, otherwise they would never get dry and firm, say about 24 feet broad, and by cutting a drain on both sides and parallel to each other the bog will gradually subside and get firm, thus forming a base for harder material. Summer is the best time to have this sort of work carried out, and before commencing great care should be taken to have all the levels properly taken, in order to save trouble and extra expense in carrying out the works. I have generally had this sort of work done by contract, the prices for which vary considerably according to the texture of the bog and other local circumstances. After the preliminaries have been finished and the surface water drained off, the small minor drains may then be cut when convenient.—J. B. WEBSTER.

Trees in Old and New England.—I have seen in an hour's drive in various parts of England more numerous and finer trees (excepting the American Elm alone) than I have seen in all New England.—EMERSON'S "Trees and Shrubs of Massachusetts."

Clematis montana.—This is, I consider, one of the prettiest of all the climbing flowering plants. Its pure white blossoms, borne so profusely, look at a few yards distant like clusters of Stephanotis. Here against a wall it rambles at will for about 8 yards or 9 yards. As the flowers last well in a cut state, I think, be a good subject for growers for market; and it is usually in bloom at Whitsuntide, when white flowers are scarce. The foliage, unlike that of most of the Clematises, is very useful for cutting during the summer months. This species stands the hardest frost with impunity.—A. BROWN, *Pusey Gardens, Faringdon.*

Magnolia Campbelli in Ireland.—One of the most annoying and (to florists) bitterly disappointing effects of the almost unexampled prevalence and long continuance of harsh north-easterly winds, with bright sun and low night temperature, during the month of March to which we have been subjected along the seaboard of Cork harbour, has been the postponement for another year at least of the flowering of the magnificent hardy Himalayan *Magnolia Campbelli*, which has not yet bloomed in the United Kingdom or indeed anywhere in Europe save in one or two favoured gardens on the banks of the Lago Maggiore, in Italy, notably in the nursery of Messrs. Rovelli, where it has also ripened seed. The finest of several well-grown specimens growing in the richly-stocked shrubbery of Mr. W. Crawford, at Lakelands, near Cork, and some 35 feet in height, showed some thirty bloom buds this spring for the first time, produced singly on the ends of young and slender twigs, but on attempting to cast their outside protecting envelopes towards the middle of March, the delicate petals inside were shrivelled up and burned black by the severe and ungenial weather that at that time prevailed.—W. E. G.

Pernettya mucronata.—Your excellent coloured plate of Mr. Lennox Davis's new varieties of *Pernettya* gives a very exact picture of the plants, and I should like to say a word in favour of these new and beautiful berry-bearing Evergreens. We have fourteen of these new varieties on a new limestone rockery here, and although they are in bud, the bright berries of last year remain thickly clustered on many of them, making a beautiful show against the limestone. For rockery purposes there is no better Evergreen shrub, as it affords a shelter without encumbering the ground, and admits of the choicest alpine plants being placed close upon its roots. No more remarkable result of patient care in the crossing of beautiful sorts, and the successful production of new forms in every shade and colour, with varieties of habit and foliage, has ever been achieved than in these new *Pernettyas* by Mr. Davis, and I can strongly advise all who are cultivating rock plants to obtain a supply of them. They are more beautiful in winter than in summer, and will be valuable for indoor decoration as well as in the hardy garden.—W. BROCKBANK, *Brockhurst, Didsbury.*

RECENT PLANT PORTRAITS.

CALADIUM L'AUTOMNE (*Revue Horticole*, May 16).—A seedling raised by the well-known raiser of nearly all the finest varieties of these handsome foliage stove plants, with leaves of the peculiar golden hue of Poplar leaves when about to fall.

ALLIUM GIGANTEUM (Regel's *Gartenflora*, plate 1113).—Apparently the largest of all the family, producing huge spherical heads of small blush flowers on the top of straight stems of about 3 feet in height, with broad loose foliage resembling that of a Yucca.

BATEMANIA BURTI AND B. MELEAGRIS (*Gartenflora*, plate 1114).—These are two brown flowered Orchids; the first and larger and more conspicuous flowered of the two is a native of Costa Rica; the latter, which has smaller and paler coloured flowers, and comes from the Brazils.

GARDEN FLORA.

PLATE CCCXC.

THE PITCHER PLANTS.

(WITH PLATE OF *NEPENTHES MASTERSIANA*, CHELSONI, AND *MORGANIAE*.)

YESTERDAY on a steep mountain side in County Wicklow I was looking at the charred turf and Furze, from which the fresh young Brake Fern fronds were springing as if quite unconscious of a scorching fire having swept over their roots a week or two ago. I was the more interested in the fact since I saw just the same thing in Singapore, only that instead of Brake Fern it was *Nepenthes* of different kinds, but principally *N. Rafflesiana*, which cropped up so luxuriantly after the forest or jungle fires. *Nepenthes* are so emphatically the offspring of a climate in which the chief essentials are heat and moisture that I have often wondered at their springing up thus, Phoenix-like, from the ashes of a scorched and blackened sod. Some plants, however, seem to like the *débris* of the fires. I shall never forget the luxuriance of *Adiantum diaphanum* growing on the site of former camp fires at the base of Kina Balu when I first had the honour of exploring the rocky sides of that great grizzly giant among Bornean mountains for Mr. Harry Veitch, and this brings me to the home or head centre of the whole *Nepenthes* family. Here on the sides of Kina Balu, or "Chinese Widow Mountain," the most strange and gigantic and interesting of all Pitcher plants are found as wild, and as free, and as unrestricted as Dock roots in an English ditch, or as Daisies and Buttercups in an English meadow. I particularly want to emphasise this point, for I find it so hard to convince ordinary stay-at-home people that all introduced plants, however rare and valuable here at home, are absolutely wild on some portion of the world's surface; all are but Groundsel or as Dandelions—weeds in the world's great wild gardens. So "weedy" are they "at home," that, as I have already said, not even a raging jungle fire blown by a north-west monsoon can eradicate their firm grip of mother earth, all of which seems to us gardeners here at home most unaccountable, seeing how erratic and exacting to boot *Nepenthes* are under cultivation in our hothouses.

HEAT AND CONSTANT MOISTURE they must ever have under cultivation, and shade is congenial alike to their health and beauty. In large airy or roomy structures they rarely succeed; a moisture-laden atmosphere suits them exactly, and too much air should not be given; indeed, very little is necessary, and more than a modicum artificially afforded proves actually detrimental to their welfare. So also of direct sunlight, which turns their leaves of a rusty colour; nor do the pitchers attain their full size or colour if too much light be admitted into the house wherein they are grown. In this way *Nepenthes* seem to be the exception proving the rule, for the largest and most highly-coloured pitchers I ever saw abroad were those on plants when growing in the shadiest part of the forest, or in deep ditches, or in water-worn gullies near rivers, and the finest and most richly coloured of all were those completely buried in dead and rotten leaves, wet moss, and rich forest *débris* of different kinds. Mentioning this fact in a letter to Mr. David Thomson some time ago, he said, in reply, that his own observation also bore out this

* Drawn from plants in the Royal Exotic Nursery, Chelsea, in September last.

fact, and I am quite sure if cultivators would take a hint from Nature in this case they might enhance the charms of these plants in the manner above indicated, and at but little trouble to themselves. Although, without a doubt, almost all the species are terrestrial, yet they seem most amiable and manageable when we suggest a sub-epiphytal mode of culture here at home. As a rule they resent pot culture, or do not arrive at full luxuriance when so grown. In loose, open compost of fibrous peat and living Sphagnum with charcoal nodules intermixed, they have been well grown in pots, but generally speaking basket culture is the better and less troublesome system, especially in the case of the dwarfer growing kinds, and I observe that the plants are never so vigorous as when the black hair-like roots escape from the heat and wind around the teak rods of the baskets or stitch themselves in and out of the living Sphagnum. Of all things when so grown drought or even moderate dryness is fatal to them; indeed I firmly believe that when the roots of a *Nepenthes* are in question dryness and death are synonymous terms. Constant syringings with tepid water is life to them. Some of the very finest

SPECIES are epiphytes pure and simple. *N. Veitchi*, *N. Lowi*, *N. Edwardsiana*, and some others are of this class naturally, although the first-named lends itself to basket culture fairly well here in our hothouses. Even *N. Rajah*, although really terrestrial at home in Borneo, seems to like its roots in fresh open compost through which moist air can permeate freely here with us. A seedling plant of it given to me by Mr. Veitch absolutely refused to grow, and was well-nigh rootless until by accident the root-stock became exposed below the compost, when it at once emitted roots and is now growing away quite freely. *N. Northiana* (of which an illustration lent by Messrs. Veitch appears at p. 496), from the limestone rocks in Sarawak, also seems similar to the last in growth, and may also do best under cultivation if treated in a sub-epiphytal way. Both these plants are naturally so robust and noble in leafage that probably these cultural hints may enable growers to manage them even better than already has been done. I must again reiterate here my opinion that

THE DAY OF PITCHER PLANTS is yet to come. We yet want two or three of the very best of all the Bornean species. *N. Wardi*, a grand species from the Seychelles in the way of *N. Lowi*, is as yet quite unknown in our collections; then there are the species from New Guinea; and who shall say what noble species there are not yet to be found on the limestone peaks of Mount Mulu or in the cloud-zone of Tilong, in North-eastern Borneo, not far from the place where poor young Ilatton, the explorer, recently fell a victim to science, with his faithful Dyaks around him. Even if we knew not—hoped not for other kinds—those we already have are really wonderful in interest and beauty when well grown. To see the range of houses devoted to these plants as I saw them recently is a great treat—none the less enjoyable because I have seen a large proportion of the species in a wild state. Pleasant as it undoubtedly is to see the finest of all the kinds growing among the wet Sedges and dripping rocks on Kina Balu, one can none the less enjoy the sight of great urns dangling by the hundred in the houses at Chelsea, which one may at any time do quite safely and pleasantly without either the

possibility of snakes or the certainty of hungry mosquitoes being near one. So much for the wild species of *Nepenthes*, but we must not forget

THE HYBRID or "home-bred" kinds raised by patience and industry in our gardens at home, and by Mr. Taplin in New Jersey. Messrs. Veitch have given me a complete list of all the hybrids raised at their Chelsea Nursery, and I hope Mr. Taplin will some day at his leisure give us details as to that fine batch of seedlings he was lucky enough to raise in America some few years ago, and one of which (*N. Morganianæ*) is represented in the plate. Messrs. Veitch's list will be so handy for future reference, that it is best to give it in full.

NEPENTHES.	SEED PARENT.	POLLEN PARENT.	RAISER'S NAME.
<i>Dominii</i>	<i>Rafflesiana</i>	species	Mr. Dominii.
hybrida	<i>distillatoria</i>	" spotted	"
" maculata	"	" "	"
<i>Sedeni</i>	"	"	Mr. Seden.
<i>Chelsoni</i>	<i>Dominii</i>	<i>Hookeri</i>	"
hybrida maculata elongata	species	<i>Dominii</i>	Mr. Court.
<i>intermedia</i>	"	<i>Rafflesiana</i>	"
<i>Courti</i>	"	<i>Dominii</i>	"
<i>lyrata</i>	hybrida	<i>Rafflesiana</i>	"
rubro-maculata	species	hybrida	"
<i>Rafflesiana</i>	"	"	"
<i>pallida</i>	hybrida	<i>Rafflesiana</i>	"
<i>Mastersiana</i>	<i>sanguinea</i>	<i>distillatoria</i>	"
		(Glasnevin variety)	"

OF ALL THE HYBRIDS, however, none are to my mind so distinct, so robust, or so handsome as *N. Mastersiana*, which rivals its beautiful mother even in boldness of form and in its rich blood-crimson colour. It is a grand success, and Mr. Court may well feel proud of having originated such a noble plant, second to no other, I consider, of the *Nepenthes* we have at present in our gardens. Its constitution is so robust, that it succeeds where many of the ordinary kinds fail to grow, and those who cannot obtain *N. sanguinea* rubra may content themselves with this plant, which is nearly equal to it in beauty, and even more vigorous in habit, while its cost is very much below that of *N. sanguinea*, and below what it is likely to be for some time to come, at least. And yet if perchance some one climbing Mount Ophir on business or pleasure intent should come across a stalk of brown pods filled with good seed, it might soon be otherwise.

AT CHELSEA they have an especial knack of persuading the slender Pine leaf-like seeds to grow if once they come there with life in them. As to the beauty of *Nepenthes Mastersiana*, I need say no more; the plate tells this story pretty well, and is certainly not exaggerated in size or in colour. I may point out, however, the fact that this plant is likely to exceed all others in usefulness, since not only is it vigorous and compact or dwarf in habit, but it is singular in its power of retaining its old leaves and their dependent pitchers fresh and beautiful for a long time, longer by far than is the case with any other *Nepenthes* at present known. At Chelsea, where the plants figured were drawn by Mr. Moon, I recently saw leaves and urns quite two years old, and yet they were almost as fresh as the six months old pitchers beside them. Altogether this hybrid may be considered one of the best ever raised—the best we should say in its own family. *N. Chelsoni* raised by Mr. Seden, and *N. Morganianæ* raised by Mr. Taplin when at South Amboy, New Jersey, are both good varieties of great beauty, and therefore most valuable from a decorative point of view.

F. W. B.

SEASONABLE WORK.

FLOWER GARDEN.

PAMPAS GRASS.—This is one of the noblest and most graceful of all the large ornamental Grasses, but, unfortunately, it is not perfectly hardy, scores of plants having died from the effects of the severe winters of 1880 and 1881; therefore, in exceptionally sharp frost a little protection is necessary, and there is nothing better for this purpose than Bracken, worked round about the base and crowns of the plants. In deep, loamy soil this Grass attains a height of from 10 feet to 12 feet, the spikelets of flower growing even taller than that. The most suitable positions in which to plant it are single specimens in front of evergreens. The plumes of flower are thus shown off to the best advantage. Another equally good position is on the banks of a lake and in large clumps in woods, especially in such spots as can be seen from the windows of the mansion or the walks of the pleasure grounds. It is easily raised from seeds sown in heat in spring, and by division of the roots at the same season.

SUB-TROPICAL PLANTS.—Having finished planting ordinary kinds of bedding plants, sub-tropical plants should now be put out without delay. As to arrangements, they must necessarily be varied according to plants at command, position of garden—sheltered or exposed—and size and shape of beds. Our opinion, confirmed by practice, is that an entire bed of a species looks better than the incongruous mixtures that one sometimes sees; but this is a point that is best settled by each planter for himself. The following were among our most effective arrangements last year, some of which it is intended to repeat this: A large oval-shaped bed of *Ricinus Gibsoni*, with central plant of *R. Obermanni*, undergrowth of *Gnaphalium lanatum*, and edged with *Chamepeuce Casabonæ*, or Fishbone Thistle. A large circular bed had as a central plant *Eucalyptus globulus*, *Wigandia caracasana* over the whole bed, and an undergrowth of *Salvia argentea* and *Perilla nankinensis* alternated. Another round bed had for a centrepiece a plant of *Solanum giganteum*, next three plants of *Solanum marginatum*, then filled out with *Solanum robustum*, the edging and groundwork being *Lamium maculatum*. Beds of *Cannas* are planted in mixture, care being taken that the tall kinds have the central places; an appropriate edging plant for these is *Centaurea candidissima*. Palms, *Dracenas*, *Acacis* *lophantha*, and *Yuccas* look well in mixture, and a bed or two of these is desirable by way of variety. As soon as planted the plants should be staked and the surface mulched; there will then be no risk of a check either from drought or wind.

HERBACEOUS AND MIXED FLOWER BORDERS.—These are now very gay with *Pyrethrums*, *Aquilegias*, *Campanulas*, *Delphiniums*, *Geums*, *Pæonies*, *Potentillas*, &c., all of which need an occasional overlooking as to ties and supports, the removal of dead flowers and weeds. Any open spaces should be filled up by the planting out of seedling biennials, such as *Wallflowers*, *Sweet Williams*, *Canterbury Bells*, and *Delphiniums*, or, failing these, with *Asters*, *Stocks*, *Zinnias*, and *Everlastings*, and in back part of borders with single *Dahlias*, *Sunflowers*, and *Hollyhocks* for autumn flowering. Bulbous plants that have matured their growth should have their tops cleared away, and if time can be spared for such work—which, unfortunately, is very rarely the case—the bare places should be filled with surface-rooting plants, such as *Sedums* and *Saxifrages*.

GENERAL WORK.—This now principally consists of mowing, clipping turf verges, box edgings, the watering of lately-moved shrubs and *Roses*, and the syringing and washing of the latter to free them from blight, which is this season very prevalent. Keep bedding-out plants well supplied with water, and peg into form all that need such attention. It will be an aid to quicker establishment and more profuse flowering of the plants if the flowers now showing on *Calceolarias*, *Violas*, *Ageratums*, *Heliotropes*, *Pelargoniums*, *Verbenas*,

and *Petunias* be picked off, and the straggling growths of the plants pinched back.

INDOOR PLANTS.

HARD-WOODED PLANTS.—These in most cases will now be either carrying a crop of flowers or making growth vigorously, and will therefore need proportionately more moisture than in the winter, when they are comparatively dormant. With bright sun and drying winds, moisture gets quickly dried up independent of that which is absorbed by the roots, and where the latter lie thickly packed against the inner surface of the pots, they are sure to suffer if there is an absence of moisture if only for a few hours. *Cape Heaths* potted a short time back must be carefully watered until the roots have fairly entered the new soil; still they must not be allowed to get dry, or the leaves will turn brown. Give plants growing freely, or that are bringing forward a crop of flowers, enough water to support them. The freest growers require most moisture; but all should have sufficient during the active season of growth to keep the roots moving well, being careful never to give any until enough is required to moisten the whole ball.

WINTER-FLOWERING PLANTS.—Amidst the many things that occupy one's time at this season it not unusually happens that the winter-flowering stock of such subjects are annually propagated from cuttings does not get proper attention in the matter of pot room, the result being that the plants through getting cramped at the root do not grow freely afterwards. The different kinds of *Begonia*, *Plumbago rosea*, *Thysacanthus rutilans*, *Eranthemums*, *Sericographis Ghiesbreghtii*, *Salvias*, and others of a similar character should, immediately they require repotting, have prompt attention; the dimensions which the plants are required to attain will necessarily determine the size of the pots they are to occupy at the time of flowering. In the case of most things of a quick-growing character, like the different plants under notice, it is not advisable to move them too often; consequently as soon as the young stock has fairly filled with roots the 3-inch or 4-inch pots they may now be supposed to be in, they may in most cases be moved to those in which they are intended to remain. Much may be effected by the constant use of manure water from the time the soil gets pretty well occupied by the roots, provided there is no falling off in its application; in this way comparatively large, well-furnished plants can be grown and flowered in pots no bigger than would barely suffice to keep them alive without the aid of liquid manure, and if grown under favourable conditions as regards light, they will make stout, bushy growth that will often yield a greater quantity of flowers than larger plants in bigger pots less favourably circumstanced. Attend to stopping the shoots of all those things that require to be so treated in order to insure a bushy condition that will do with the least amount of sticks and ties, which should always be looked upon as necessary evils to be used as sparingly as possible.

POINSETTIAS.—If some of the old plants that were dried off after flowering were started a short time back, they will now have made shoots large enough for propagating; they should in all cases be taken off with a heel of old wood attached to them; cuttings thus secured will root in a fortnight in a brisk heat, but they must be kept sufficiently close and moist to prevent flagging. If very large heads are required, some of the old stools should be placed in larger pots, say 10 inches or 11 inches in diameter, and grown on with single stems, keeping them all through the season with their heads close to the glass, otherwise they get very tall. Smaller examples will often be found preferable to larger stock grown in the way described; but where there are large stoves to keep gay through the autumn and winter, big plants with their large heads associate best with other things amongst which they are placed.

EUPHORBIA JACQUINIÆ FLORA.—Everything necessary to insure free growth should be done

with the stock of this most useful winter-blooming plant, for the quantity of flowers forthcoming is dependent on the size and strength which the plants attain, and especially their ability to produce a second crop of bloom. Plenty of light and heat, with a little shade in the middle of the day, are essential to their well-being.

AMARYLLIDS.—Every needful attention should now be given to Amaryllids after they have flowered. Comparatively little pots suffice; but still, root cramping must not be carried too far, or the bulbs will not attain their wanted size, and their increase by means of offsets will be less than if more vigour was infused into them. Where additional room is required, give pots an inch or two larger, using good yellow loam if it can be got, in all cases ramming the soil hard in the pots and adding sand sparingly. Keep the stock sufficiently supplied with water at the roots, syringing freely every day to keep down insects, and let the plants be fully exposed to the sun. Among *Pancratiums*, *Crinums*, and *Hymenocallis* many will now be making new leaves; where large spikes of flowers are looked for the plants must have liberal culture, but with these no amount of attention in other matters will compensate for a deficiency of light; yet the foliage of some of the *Crinums* appear to be less able to bear full exposure to the sun in the middle of the day than that of the *Pancratiums*, which is tougher, but in all cases no more shade should be used than is found to be requisite to prevent scorching.

CINERARIAS.—These, like *Calceolarias*, *Primulas*, and some other plants that used to be all but exclusively propagated from suckers or by division, are now so much improved that varieties good enough for any purpose can be had from seed. Amongst these it often happens that a few plants of unusual excellence make their appearance. In such cases it is well to preserve them. When the seed which they bear is ripe the flower-stems should be cut away and the plants turned out in light soil mixed with vegetable mould, selecting a place where they will not be exposed to the mid-day sun. So treated they will make abundance of suckers that can be taken off and potted.

ORCHIDS.

EAST INDIA HOUSE.—Perhaps there are no more interesting, beautiful, or easier grown plants than the East Indian *Dendrobiums*. Most of them are now making their growths, and as these push rapidly from the base of the pseudo-bulbs, new roots also push freely from them, and whenever this occurs any plants that require shifting should at once receive that attention. In doing this all decayed composts ought to be removed without disturbing the roots. Nearly all deciduous *Dendrobiums* may be subjected to this treatment, and those that should be in every collection are *D. nobile*, *D. lituiflorum*, *D. Bensoniæ* (this species is always later than the others), *D. Falconeri*, *D. Wardianum*, and *D. crassinode*. In repotting or placing them in fresh baskets, see that the potting material (good fibry peat, Sphagnum, broken pots, and bits of charcoal) does not cover the young roots, as they like to run out on the surface and strike downwards themselves. The plants will require to be freely watered, as they would be injured if allowed to get dry. If any shoots start from the upright stems they will also root freely. They should be cut off with a portion of stem attached, and be planted in small pans or baskets. They like a high, moist atmosphere while they are making their growths, and up to the time when the growths are completed. *Dendrobium Dalhousianum* and the allied species, *D. moschatum*, are not so much grown as they ought to be; they form noble pendulous spikes, and if the plants are removed to a cool house when the spikes open they will last nearly a fortnight. If left in the warmest house they will not last more than five or six days. They require good supplies of water while developing their spikes. It is not necessary to repot them often, as they make the best growths when rather pot-bound. Much arti-

ficial heat will not now be required. It is easy to keep the temperature up to 70° with a little air on all night. Atmospheric moisture should be kept regular by means of evaporation from the stages and paths. The young growing shoots of *Dendrobiums*, such as *D. Devonianum* and *D. Falconeri*, may be syringed every day to keep red spider in check.

CATTLEYA HOUSE.—There will now be a great wealth of bloom in this house, and it must be kept in good condition as long as possible. A very moist atmosphere, especially if there is little or no warmth in the hot-water pipes at night, causes the flowers to spot. We do not care to throw any water about in this house, say, after three or four o'clock p.m., and if the pipes are kept comfortably warm with sufficient air on all night, the blooms will last a long time if the plants are also kept dry at the roots. Treated in this way, *Cattleya* flowers will last for three or four weeks. *Odontoglossum citrosum* is also in great beauty, but the flowers of this have even a greater tendency to spot than those of the *Cattleyas*. They require much the same treatment. We ought to say that letting such Orchids become comparatively dry at the roots may be slightly injurious to them. *Odontoglossum Roezli* is also now in great beauty; the flowers of these last well on the plants. As soon as removed, dip the plants in the solution previously recommended to kill red spider and thrips. The same remarks apply to *O. vexillarium*. The different species of *Anguloas* are now in bloom, and with the flowers the young growths will be pushing strongly, and consequently the roots also; they will, therefore, require plenty of water. The yellow aphid, which is very troublesome, must be eradicated very speedily on its first appearance, or it will get into the insides of the flowers and will be difficult to dislodge without spoiling them. On *Vanda suavis* flower-spikes are now showing themselves freely. This is a very showy, nay, a grand, species when well clothed with foliage and flowers. It succeeds best in a *Cattleya* house, and when it is found that plants of it retain their foliage in any one part of the house better than another, and grow more freely, it is best to leave them there. One of the best of the *Aerides* is the Indian Fox-brush (*A. Fiedlingi*), now in flower; its long-branched flower-spikes, usually very freely produced, are generally admired. Its leaves are sometimes infested with thrips, which must be cleared off with soap-water to which a little Tobacco liquor has been added. Green fly will also get amongst the flowers when they are opening. Brush it off before it does any injury. If the Sphagnum is kept in a healthy growing condition on the surface, the plants usually do well. In potting we fill the pots well up with clean drainage; the potting material consists of about equal parts broken pots, charcoal, and Sphagnum, finishing off with clean live-chopped Sphagnum on the surface. The temperature of the house will range about from 60° to 65° at night.

COOL HOUSE.—The largest proportion of the choice *Odontoglossums*, such as *O. crispum*, *O. cirrhosum*, *O. Pescatorei*, &c., will have now passed through the flowering period; of course, some are yet in flower, and others will bloom at intervals through the summer, the great value of *O. crispum* being its tendency to produce flowers all the year round. We have had plants which produced fine, strong spikes for three or four years in succession, and out of a dozen plants we had some of them in flower every month in the year. After flowering so freely for that period, the strain upon them seemed to be too much, for they did not make strong growths, and produced very weak flower-spikes for the next two or three years. The question is, should not the plants be prevented from flowering so continuously, especially when the flowers are allowed to remain on them until they fade? We think they should; the ultimate result would be more satisfactory. *Odontoglossum vexillarium* will flower itself to death in a period of four years, or at least become so exhausted, that the plants are not of much value afterwards. We have a few plants in this

house that ought to have been potted early in the year, but for several reasons they did not receive that attention. These will be seen to at once, or if they cannot be potted before May is out, perhaps it will be better to leave that operation until the autumn. The beautiful *Ocimum macranthum* is quite a feature in the cool house, its large golden flowers are so different from those of any other kind. It seems to like a good supply of water when making its growth, and the slugs are particularly fond of the young roots which are formed above the surface of the compost. The flowers are now opening on some of the plants, but as a rule this species does not flower until the end of June or July. Every night the plants ought to be looked over for slugs or small snails.

MARKET FRUIT GARDENS.

GOOSEBERRIES are now one of the principal crops requiring attention, not only as regards gathering and marketing in a green state, but also as respects warding off the attacks of caterpillars, which have for the last few years been very destructive. In plantations in which they were allowed to strip the foliage off unchecked last year there are very few Gooseberries to gather this season. Hand-picking, dusting with Hellebore powder, fresh slaked lime, and other remedies, such as placing under the bushes sacks smeared with tar on which the caterpillars are shaken, are being used. A good crop of Gooseberries, even at a moderate price per sieve, is a very remunerative one, as the yield per acre is very great where the land has been well treated. Small starved berries on bushes that look yellow and make hardly any young wood are useless for market; large berries grown quickly on bushes that are deep green in colour, owing to high feeding at the root, are the ones to pay. Where good rotten farmyard manure can be obtained there is probably nothing to surpass it as a winter dressing forked in lightly about the roots. It is a common practice to grow bush fruits under standard Apples, Pears, Plums, &c., and thus situated they do very well for a few years, but if really first-class bushes are wanted to yield annually heavy crops, there is nothing like letting them have the land to themselves. On good land, planting them 9 feet apart each way is not too much space. Red and White Currants should now or soon have the tips of the growing shoots pinched off, an operation which greatly helps the swelling of the crop, and assists the buds on the spurs to swell up and ripen well for next year. There is at present a great quantity of caterpillar, fly, and other pests on fruit trees and bushes. Washing with soft soap dissolved in water so as to make a mixture like strong soap-suds, and applied with force from a powerful engine, such as is employed for washing Hop bine, is the usual remedy in this part; even if the foliage gets partially destroyed by vermin the chance of next year's crop is gone, as well as the present one, that invariably drops prematurely if the foliage is injured to any extent.

HOING by manual labour, or scarifying with a horse or pony, is now being actively carried on, for, in addition to the need for destroying weeds, the production of a mellow, friable surface-soil is of great benefit to the growth of both trees and bushes. Large, heavy horses are not required for this operation; a pony, or even a donkey, will draw a light set of hoes set in a frame, and, with a careful driver to avoid injury to the trees, a large amount of surface soil may be stirred in a day, and as the trees or bushes are planted in straight lines each way, there is very little ground left unstirred, except close to the stems, where a man following with a draw hoe completes the work.

GRAFTED TREES require frequent attention, for where growing strongly the ties will need loosening, or they will cut the bark. As soon as the shoots get long enough to sway about with the wind they must be staked on both sides and loosely tied with stiff bast; this will keep them from snapping off. Trees grafted last year will now need divesting of all shoots produced by the stock,

so as to concentrate the energies of the trees in the grafts; take them off close to the stem with a sharp knife. Espaliers or wall trees, whether on farm buildings or other walls, should have all surplus shoots pinched back to three or four leaves while they are yet soft, removing all curled or blighted foliage, and washing the remainder with soft soap or Gishurst compound, consisting of about 4 oz. to the gallon.

FRUIT.

CHERRIES.—When the fruit on the early-forced trees is ripe, keep a free circulation of air through the house and damp the floors and walls every day, but discontinue wetting the foliage in near proximity to the fruit, which must be kept perfectly dry. If the house is light and bright, and it is thought advisable to keep the fruit in a plump condition for a considerable time, it will be necessary to shade lightly when the sun is very powerful, but shading must not be overdone, neither must it be left on the roof where it is not wanted, otherwise the fruit will soon mould and perish. The best shade of all for ripe Cherries is the tree's own foliage, and to insure this great care should be devoted to stopping, tying in, and regulating the young growths, so as to have a regular spread over every part of the house. This remark applies to permanently planted trees, as trees in pots, which soon leave off making much growth and only form spurs, can be removed to other houses, or even a dry, airy fruit room at pleasure. When all the fruit is gathered, good syringing will be necessary, and if the roof-lights are portable they may be taken off the house without delay, while pot trees may occupy a light, open, but sheltered situation in the open air where the roots can be protected with Fern or litter to economise watering, and the heads can be washed with the engine to preserve the foliage and keep it free from insects.

PLUMS.—If Plums and Cherries have been grown together, the difficulties which have often been pointed out will now be felt. All goes well with these two valuable additions to our early dessert until Cherries, which come in quickly, begin to ripen, and it then becomes imperative that we find fresh accommodation for one or the other, hence the importance of growing the Plums or Cherries in pots or tubs, and as either submits kindly to pot treatment, the choice is a matter which may be governed by circumstances. If the two are only divided by a glass partition, then the Plums may have more heat than would be good for Cherries, provided a liberal supply of air be admitted, and the swelling of the fruit is helped forward by early closing on fine afternoons. Continue the regular syringing of the trees until the fruit begins to change colour, using clear, soft water, or water which will not deposit sediment, for the purpose. Mulch permanently planted trees and water copiously with tepid water, but avoid producing a too gross habit in vigorous young trees by feeding before they begin to feel the weight of the crop. Top-dress pot trees with rich material, and feed with good liquid at every watering. Stop all strong and surplus growths at the fourth or fifth leaf, and guard against over-cropping, particularly where the best late kinds, like Golden Drop, are expected to become very fine, and to hang on the trees for a considerable time after they are ripe.

PINES.—A long period of bright dry weather having been highly favourable to sharp forcing without the aid of over-heated pipes, early started Queens have made rapid progress, and successions are throwing up clean vigorous shows, as is generally the case after a mild winter. In the fruiting department maintain the temperature ranging from 70° at night to 85° by day, and give moisture in proportion to the amount of fire-heat required. Also keep the evaporating pans regularly charged with water, to which strong liquid or a pinch of guano may be added twice a week, and lightly dew the plants over with tepid water after closing, and when the axils of the leaves become dry. If not already done, see that each fruit

is properly secured to two sticks, with cross-ties for keeping the crowns upright. Rub off all gills and offsets and reduce the suckers to one, unless the stock is scarce, when two may be left without robbing the fruit. As the greater portion of the September potted plants will now be showing fruit increase the supply of stimulating liquid, and if not previously done make them firm in the pots by placing pieces of fibrous turf round the stems. If any have missed fruiting, draw them out and submit them to a month's rest by plunging in a bottom heat of 75° with a free circulation of air. Dispense with fire heat as much as possible; let the temperature range from 65° by night to 80° by day; discontinue overhead syringing, and only give sufficient water to prevent the roots from feeling the ill-effects of drought. Keep successional plants growing on without a check until the pots are well filled with roots. Pot up small batches of suckers at short intervals, and divide the whole stock into small sections where a continuous supply of fruit is expected from a limited number of plants.

VINES.—Gradually reduce the temperature in early houses in which the Grapes are quite ripe, and maintain a fresh, healthy atmosphere, by damping the floors, and by giving just enough gentle fire-heat to admit of a free circulation of air. Cleanse the foliage with clear water as the Grapes are cut, and stop any extra strong growths to encourage a general break of laterals all over the Vines. Succession houses in which the fruit is now colouring may have more air whenever the weather is favourable, and a nice circulation throughout the night will be highly beneficial to the Vines, particularly where they have been hard pressed and perfect finish is doubtful. If Madresfield Court Muscats are growing with the Hamburgh, see that the roots at the time they commence colouring are in a nice growing border, neither too wet nor too dry. Mulch well to keep in moisture, as moisture after the skin is set causes many of the berries to crack, and allow all the laterals to grow to their full extent until after the fruit is cut. It will then be necessary to shorten back, and give more water to plump up the buds. Look over the main crop of Muscats, also the choice late kinds intended for autumn and winter use, and if any of the berries show signs of remaining small, let them be removed while there is yet time for those properly fertilised to fill up the weakest parts of the bunches. In the selection of the bunches of Gros Colmar and other sorts intended for bottling always give preference to medium-sized taper bunches of good outline, as they generally set well and keep better than larger clusters through which the air cannot pass so freely. Persevere with thinning the latest crops as they become ready. Mulch and water the inside borders as soon as this tedious operation is finished, stop gross laterals where they are likely to rob the fruit and weaker growths, and then help them along to the stoning period with plenty of heat, air, and atmospheric moisture. If late spring planting has not been finished free young Vines from this year's eyes may be put out up to the end of this month with every chance of their filling the trellis. Two points are essential to success; the borders should be made inside the house, and the temperature of the compost should not be less than 70° when it is placed in contact with the roots. For this kind of planting Vines struck in sods of turf are preferable to those which have been grown in pots.

KITCHEN GARDEN.

THERE is no operation in this department so useful or so profitable as mulching. It keeps the ground moist, smothers all weeds, and forms the finest path possible to walk on to gather the produce. Spring Cauliflowers are also mulched, and so strong and healthy are our plants, that after the heads are cut they send up strong offshoots, which in due time form small heads just the size for table. Hoeing among growing crops is the very life of vegetation. During the last six

spring Onions have turned yellow, occasioned by the sharp cutting east winds. We now sow them in the last week in March. It is a great mistake to sow small seeds outside early; they come up weakly, get stunted, and generally end in failure. Young Broccoli and other plants now making their appearance will be much benefited by being slightly damped the first thing in the morning and dusted over with a little soot and dry sand; small plant beetles play sad havoc among them, except such attention is paid to them. Sowing Lettuces (White Cos) on the Celery ridges where they have to stand is a step onwards. We never grew such fine examples of Lettuces as those sown with the Onions and allowed to stand and come to maturity; in fact, this practice of sowing seed where the plants are to stand is creeping slowly, but surely, to the front. Of Broccoli, we are still cutting some very fine specimens of Cattell's Eclipse.

KITCHEN GARDEN.

YOUNG CARROTS.

WHERE these are in regular request, as long as the weather will favour their growth, sowings must be made. For the first sowing we put up a hotbed about the end of January, and in order to secure a lasting temperature we use three parts leaves and one of stable manure. A frame furnished with glass lights is put on the bed, and about 6 inches of rather fine soil is placed in that on the surface. The seed is sown in drills 6 inches apart. Only an ordinary degree of attention is required in the way of watering, covering, and air-giving in order to produce young Carrots as large as one's finger by the end of April, and this is the size most in favour. The first crop to be obtained from the open ground should be sown early in February on a warm south border, the soil of which is light and rich. The most sheltered position should be selected, where they are not likely to feel the effects of late spring frosts, for even on south borders there is often a great difference as regards frost effects. For pulling when young I like all outdoor crops to be sown broadcast, and thinned if they come up rather thicker in places than is required. Where the demand is great another sowing should be made the third week in March, near that first sown. These two crops will invariably carry on the supply until the main crop, which is generally sown early in April, comes into use. To maintain a supply of successional crops a fresh sowing must be made in the open ground once a month up to the middle of August, after which the season will be too far advanced for sowing out-of-doors. For summer crops the seed may be sown in any part of the garden that is fully exposed to the sun; but as a large space for each sowing is unnecessary, a south border is as suitable a place as any for them. I may mention here that I like the old English Short Horn as well as any of the sorts for drawing when young. In gardens where pits and frames cannot be devoted to the production of a supply through November and December it is a good plan to sow a rather large breadth on a south border about the middle of August, and when frost occurs in November to cover the young plants up with dry leaves or Bracken. This will afford a supply for several weeks, but they will not be so fresh and tender as those protected by glass lights and kept free from frost; therefore where a brick pit can be spared it should be used for them. Bottom heat is not a necessity in this case, but the pit must be filled with half-rotten manure or some other material, and 6 inches or 8 inches of soil should be put on the top of it so as to bring the surface within 10 inches of the glass. The seed should be sown the second or third week in August, but the lights need not be put on until the middle of October; even after that time, however, plenty of air must be given, and the glass protected during frosty weather. In ordinary seasons a supply from this source ought to be obtained up to the middle of December.

J. C. C.

CUCUMBERS AND MELONS.

WHEN bedding plants are put out, pits and frames cannot well be better employed during summer than in growing Cucumbers and Melons, either of which do exceedingly well in such structures. To enable this to be done, however, they must be fairly started on a little bottom heat and the longer this lasts the better will they thrive and bear fruit. The first thing, therefore, is the fermenting material; the best and most desirable, so far as heat is concerned, is

TAN, which may be got in almost any quantity in towns for a mere nominal sum, and often for the labour of carting. The great point is to obtain it fresh, as that which has been lying exposed to the rain and weather loses its virtue and strength, and does not retain its warmth long, but fresh material will keep in a regular state of fermentation for months. Being of a mild, sweet nature, tan requires little or no preparation, but may be put into the pit at once, and the bed made and the plants turned out as soon as the heat gets up.

STABLE MANURE AND LEAVES, or the former and tan, also make capital hotbeds, the manure being almost indispensable for beds to stand frames on, as they cannot well be built up without it, the tan or leaves being altogether too short alone. In using horse manure it will be necessary to be very careful, as it is fiery stuff, the fermentation of it being violent, to correct which and get rid of the injurious gases it evolves, the manure should be got together in a large heap and turned over several times during the week. This will let out the rank steam and sweeten it, and as soon as this is done, it will be in fit condition for use. The size of the bed must be ruled by that of the frame, but for this latter to have plenty of base to stand on, it is always as well to build about a foot larger all round, the proper height being about 2 feet 6

inches when settled, which body of stuff will hold the heat for a considerable time. When built and the frame on, the next thing is to get in

THE SOIL, but before doing this it must be decided whether Melons or Cucumbers are to be

garden earth does very well for Melons, and this, when put in for them, should be trodden down, and as soon as it gets warmed through all will be ready for the plants. These should be young, healthy, and vigorous, and to fill each light

properly, two are needed, as one can then be trained from the middle to the front, and the other be led to the back. The way to manage

MELONS, so as to get them to cover the spaces quickly, is to stop the main shoot by pinching out the end, when, soon after, the plants will break below, and the shoots formed can then be trained out by the aid of a few pegs in any direction required. As soon as the ends have reached the boundary allotted for them they must again be stopped, the laterals and the main branches then throw out speedily numbers of flowers. These must be set when expanded by taking the male blossoms and using the pollen by touching them with it in the centre, by doing which they become impregnated and at once begin to swell and grow larger. As soon as they are about the size of Walnuts or eggs, and it can be seen they are safe, the fruit should be thinned, from four to five being quite enough for a single plant to carry out and finish off to perfection. It should be borne in mind that Melons when swelling their fruit want plenty of water, which ought always to be warm, and may be poured over them through the

Miss North's Pitcher Plant (*Nepenthes Northiana*). Pitcher about half the full size. Recently introduced from Borneo. (See page 492.)

grown. If the latter, the soil cannot well be too rough or loose, as Cucumbers like it in that way to run in, and though Melons likewise prefer coarse soil, it is necessary to make it very firm for them, or they grow far too strong and are shy in their fruiting. What Cucumbers do best in is the parings from the edges of Grass verges or newly-dug turf, which, chopped up, is just the thing for them, as being so full of fibre it affords them the food they require. Heavier stuff or even common

rose of a watering-pot, so as to wet the foliage, which, if done, as it should be, early in the afternoon before closing the frame, is very refreshing. As the fruits approach the ripening stage it is requisite for the plants to be kept drier, or the fruit will be of inferior quality, but to maintain the leaves in a green healthy condition it will be necessary to syringe or sprinkle them both in the mornings and afternoons on hot, sunny days.

CUCUMBERS enjoy this treatment too, and the atmosphere for them cannot well be too moist, as a humid, warm air is what they delight in. Many who grow Cucumbers go to great pains in setting the fruit in the same way they do Melons, but unless seed be required they are better without that operation being performed, as it helps to fill the fruit with seed and pulp in the middle. In growing either Cucumbers or Melons in frames or pits, the thing is to make the best use of the sun by closing at three o'clock or soon after, as then plenty of heat is shut in for the night, and the moisture with it keeps the plants strong and healthy. S. D.

Diseased Cucumbers (*F. G., Saxmundham.*).—Your Cucumbers are badly attacked by the disease termed by gardeners "gumming." It is immediately recognised (especially if a lens is used) by the small pieces of exuded material which greatly resembles gum arabic. It is sometimes accompanied by a fungus (as in your case), termed *Glaeosporium*. The disease is probably brought about by some defect in the mode of culture, but Cucumbers under the best treatment often show this disease, and it commonly baffles all treatment, even by the most experienced hands. They may improve as the season advances; if not, discard them and begin afresh. —W. G. S.

Late Peas.—Like Mr. Clarke (p. 455), I have not one word to say against *Ne Plus Ultra* or British Queen, although I consider the former the better Pea of the two. But of all Peas that I have tried, I, like Mr. J. Muir (p. 455), find none to equal Laxton's Omega for the last crop. It has this advantage over the other two varieties, viz., that it is dwarf and can be easily netted, an important point with regard to late Peas, in the case of which birds, especially tits, are very troublesome. I have had whole rows of the tall sorts spoilt by them, while Laxton's Omega has been secured under nets. —J. PARKES, *Northiam*.

—We annually grow a goodly quantity of late Peas, which are a daily necessity until far in October. We cultivate several kinds. British Queen is wholly discarded, and *Ne Plus Ultra* is occupying much less ground than formerly, both being replaced by Laxton's Omega, in every respect a most desirable variety. It is indeed the best late Pea with which I am acquainted. The other kinds just mentioned do not turn out at all satisfactory in wet autumns, being all haulm and no pods, and even in favourable seasons, not remunerative, as they require too much ground compared with the crop which they bear. —JOHN ROBERTS, *Tan-y-Bwlch, Merionethshire*.

Stott's Monarch Rhubarb.—Since I have known this fine Rhubarb I have been pleased with it. It is a sturdy sort, a real giant among Rhubarb, but in spite of its size it is tender, juicy, piquant, delicious, and, to my way of thinking, there is no sort grown which can compare with it. I write this, as your correspondent "A. D." says "there is no desirable feature in it." Now, my opinion is that every feature it possesses is desirable, and it grieves me to hear an old friend so spoken of. My opinion of Stott's Monarch Rhubarb (introduced by Stuart & Mein, Kelso, N.B.) is that if known no other Rhubarb would be grown in English gardens, except for forcing purposes, for I do not think it would bleach well. Late in the season, too, when old and past itself as a "pie plant," as the Americans call it, it makes a most delicious preserve. —W. H. CULLINGFORD, 7, *Phillimore Gardens, Kensington*.

Varieties of Rhubarb.—When I came here, now over ten years ago, I found two sorts of Rhubarb, both of which I had no recollection of having met with previously. The earliest sort is a really fine one, and quite distinct in flavour from all others. Its stems are rich crimson in colour, and as they sprang up so very early, I enclosed them in boxes on the ground for first use; with this protection only they came in in the beginning of February, and in mild weather sometimes sooner. It is small both in stalk and in leaf, but

very tender and delicious. Another, growing somewhat similar and nearly the same in colour, but stouter in the stalk, comes in just about the same time as the Victoria, and is preferred to that strong-growing variety, with which it is associated. I have not met with Johnston's St. Martin, but from descriptions of it which I have seen I have always fancied it to be the same as the early variety just mentioned. The second sort named can hardly be reconciled with "A. D.'s" Champagne (p. 460), as, although comparatively dwarf, it is much stronger than the first, which is contrary to his description. —R. STEVENS, *Paston, Northumberland*.

ROSE GARDEN.

ROSES AND THEIR ENEMIES.

THE Rose has so many enemies that it is hard to say which does it the most harm, but I think we are safe in concluding that the two principal ones are the aphid and the "worm i' th' bud," the latter being (I gather in translating from Lacharme's interesting book, "*Le Rosier*") the larvæ of the hymenopterous *Selandria excavator* and of the saw-fly (*Hylotoma rose*). On my Rose trees this spring I notice two distinct kinds of grub at the points of shoots on the standard Brier working vigorously at the newly-inserted buds as well as on those Brier buds which were left to draw up the sap, but on my dwarfs they are strangely conspicuous by their absence, hence, I presume, I am honoured by the presence of both the species named; on the other hand, the dwarf Roses seem, as if by mutual understanding, to be the peculiar prey of the aphid. For this caterpillar there seems to be no effectual remedy beyond a vigilant use of the watchmaker's lens, and a small penknife wherewith to open the tender, almost brittle young leaves in search of it, of course instantly crushing the marauder in case of a successful find. Where it is too late and the mischief done, we may derive some consolation from the fact that the young bud sends out in most cases two shoots in place of the one eaten, though the blooming of the Rose is delayed a month. It is almost impossible to find the young of the sawfly earlier than when operating, for the female deposits her eggs in a longitudinal incision made in the bark of the Rose tree by its saw, the minute head only of the larva afterwards being visible. By a wise foresight the fly, after laying the eggs in parallel grooves, gives a cross-cut above them and at right angles (similar to the cross-cut in budding), so as to arrest the downward flow of the sap which would otherwise heal up the wounds, and at the same time effectually entomb the young grubs or eggs. This cross-cut also causes the shoot to bend slightly, by which the presence of the enemy may frequently be detected. It is very admirable, but annoying also to note the wisdom of the sawfly in depositing its eggs near the summits or ends of the young juicy branches, so that a suitable repast may be at hand for the sustenance of its progeny. I may remark that where the "worm i' th' bud" is plentiful it will be better for more attention to be given to the cultivation of Roses on the Manetti or on own roots, my experience being that the standard Brier is their home and happy hunting ground. For the prolific viviparous aphid with its one sexual acquaintance sufficient for the birth of six succeeding generations, no one word of good can be said. Born alive at the rate of seventy per day from one mother, it instantly digs its beak into the soft skin of the young shoot or leaf and feeding on the juices of the plant, itself in turn giving birth, as Canon Hole says, "without love, courtship, or matrimony," to the next generation. We must, however, in our wholesale crusade against the aphid remember that we have many allies, sparing them when examining our trees, for they are even more intent than we upon the destruction of the pest; in fact, were it not for its wonderful fecundity it would soon succumb to the survival of the fittest. Although dealing with insects, it would be unfair not to mention the number of

small birds which we should entice to our Rose beds by a few bread-crumbs, so that whilst there they would no doubt catch sight of the aphid and work their way up the branches, consuming thousands. Ants also should be encouraged in the open garden instead of destroyed, for they are so fond of the sweet excrement from the aphid that they will seek them out and suck them to death. Next amongst our friends comes a very small ichneumon fly (*Ophion lutea*), which alights on the body of this aphid and deposits an egg in it; the wounded victim then separates from its companions, changes from green to rose colour, then to bronze, finally drying up in favour of the larvæ within it. The larvæ of the fly (*Syrphus pyrastris*) has a most curious and interesting method of helping us. The female lays its eggs, eighteen to twenty in number, from early April to September on Rose leaves laden with aphides; about a fortnight later the young larva appears, being provided with a spear or dart in its head. It has the power of standing on its hinder quarters, so to speak. Seeking in all directions for the aphid, and finding one, the spear is instantly protruded into the body of the victim and withdrawn with it impaled, from which the contents are sucked. This is done so rapidly that one has been seen to catch and consume six aphides in seven minutes. A keen watch in spring time with plenty of syringing (washing off the early female aphid, mother of the summer crop of many generations) is, so far as we are concerned, the most we can do. They rarely have strength to resume operations so far away, whilst should any of our little friends the ants or flies go with the rest they are no worse for the drenching. In various works we are told to suspect all insect life, yet as suspicion does not necessarily mean condemnation, I suggest to Rose growers that every insect and grub on Rose trees should be spared with the exception of the aphid and the self-evident grub frequenting any shoot points. R. A. H. G.

Horsforth, near Leeds.

ROSE PROSPECTS.

"D. T. F." writes so despairingly of the prospects of the forthcoming Rose season, that I cannot help thinking and sincerely hope that his case is altogether exceptional, and his losses must be due to other causes besides bad weather. Here in Durham the prospects never looked brighter, and with ordinary weather from now (May 28) Roses promise a glorious harvest of bloom, and this too in spite of the recent cold north-east winds and severe frosts in March. My own plants, pruned closely down early in February, are at the present time full of stout healthy shoots, and instead of there being a paucity in this respect, the only regret seems to be the nerve and time required to reduce the number of fine healthy growths to a reasonable number to prevent the plants being overcrowded. The only losses here are a few small plants on own roots, planted out early in April, and which ought properly to have been potted on and planted later; but Roses do so well here on Manetti and seedling Brier, and the plants never seem to grow old, that any extra trouble with own-root plants is so much time wasted. I think a great deal of harm is often done by late pruning, which often results in weak, unhealthy growth. The greatest drawback we northern exhibitors have to contend with this year is the lateness of the season, which will prevent us showing at the early shows, for it is hardly probable that the plants will be in bloom before the second half of July; but even this is difficult to foretell at present, for with snow in May sufficient to stop the traffic on the railway within twenty-four miles from here (here we had cold rain), who knows but what we may have a touch of tropical weather before long, for surely the seasons now are difficult to understand.

The Garden.—General Index to the first twenty vols. now ready, strongly bound, price 12s. 6d.

FLOWER GARDEN.

HARDINESS OF PANSIES.

IN "R. A. H. G.'s" description (p. 439) of what seems to be a judiciously planted small villa garden, he mentions the protection of Pansies during six winter months. As the Pansy is one of our most valuable hardy plants, more especially in cold localities, it is as well amateurs should know that, if properly managed, Pansies require no winter protection, but may be safely left to themselves in the open border. I planted out a lot of seedling Pansies in September, 1880 (show, fancy, and Bugnot's International Prize); they made good stocky plants before winter, and were just coming into bloom when frost caught them. They passed through a severe winter, being frozen hard for many weeks, and had to stand as much as 18° of frost on two occasions, and several nips of 15° and 16°. They opened a few blooms at midwinter, and were the first flowers I had in the spring, continuing in bloom until July. The purple selfs seemed to be the hardiest, then the crimsons, then the yellows, whites, and belted kinds, while the latest to bloom were the blotched flowered kinds with light grounds and the russet coloured ones. Not a leaf was injured of any of them, although the blooms, which were frozen hard for six weeks, were injured. The locality is cold and fully exposed to east and north winds. A part of one of my beds is excessively exposed to north and east winds, the wind being concentrated by buildings and shot across it as from a pair of fanners. The cutting frost winds of last March damaged in this bed the springing leaves of Tulips, *Anemone coronaria*, *A. fulgens*, *Phloxes*, *Hepaticas*, *Daffodils*, *Polyanthus*, *Narcissus*, *Gentiana gelida*, and *Scilla sibirica*, and destroyed those of *Polyanthuses* and *Primroses*, but Pansies and alpine *Auriculas* escaped unhurt. If an amateur has a good collection of named Pansies, he can keep his decorative beds and borders stocked with strong seedling plants sown in July or August with hardy biennials, and treated the same as these. Seedling Pansies are very accommodating as to soil and situation. I have a few now planted in a shady border where they never see the sun, and where they trail between clumps of *Spiraea japonica*; they do not flower freely, but give blooms in the heat of summer. I have also grown them successfully on a hot, sunny border facing southwest, with the help of a plentiful dressing of leaf-mould, and watering late in the evening when the ground had cooled. The method described by "R. A. H. G." is the readiest for propagating anything that may be thought worthy of preserving either as regards flower or habit.

J. D.

HARDINESS OF THE AURICULA.

THE *Auricula* exhibitor who told "J. M." at a late show that the *Auricula* could not be well grown out of doors must only have known the plant under glass. Gardeners and thousands of cottagers know better. Named varieties of *Auriculas* were amongst the first lots of hardy plants ordered by me for the garden here ten or twelve years ago, and though I have added to the stock since by seed and otherwise, I have still many of the original plants divided and re-planted at times, and not one of them have ever received the least protection. I have been familiar with the *Auricula* as one of the hardiest border plants since I first grew it in my father's garden many years since in a cold locality in Scotland. Our plants are large, and at present are as vigorous and broad-leaved as young Cabbages. I have cut off lumps with the spade this season, and in times past as big as my head, to give away, and that is our usual way of lifting and planting them. I had plants moved from a border in April just throwing up their flowers, six roots of which filled

a wheelbarrow, and on one of these plants now on the rockery I counted to-day close upon forty trusses bearing about 500 flowers at least, for they were too numerous to count, and many had faded during the past warm week. We have scores the same, and have been cutting basketfuls for a long time back. Two or three-year-old plants from seed do best, but offsets do well also, and the hardiness of the plant depends a good deal on the situation. It is most enduring on the rockery, but flowers best on a rich border. I know nurseries where they are grown by the thousand from seed, and one noted *Auricula* grower at least makes a good thing by selling his seed to the trade for outdoor culture. Even the flower-buds are wonderfully hardy. In March we had a spell of frost and cold winds which did much damage to shrubs and other things, but did not harm a single *Auricula* bud that was not expanded; they never were finer with us than they have been since. Why the *Auricula* should be so little grown in flower gardens has always been a puzzle to me, but I believe that in many cases it is because gardeners entertain an erroneous impression of its hardiness from the teachings of the

Varieties of white *Narcissi* (all much reduced).

2, *N. tortuosus*.1, *N. albicans*.3, *N. cernuus*.

florist. It is pretty well known, moreover, that those who grow *Auriculas* by the hundred or thousand under glass are not actuated by mere love of the flower. It is their interest to foster its culture as a florist's hobby, and some of them make a good thing of it in a commercial sense.

J. S. W.

NOTES ON HOLLYHOCK CULTURE.

CHOICE varieties of Hollyhock are usually grown in pots during winter; they are propagated in spring, and the young plants raised in that way are placed under glass until large enough to be inured to the open air, after which they are planted where it is intended they are to flower. Our plants have been out for some weeks; at first cold nights sadly checked their growth, but since the weather has taken a favourable turn they are making good growth. Hollyhocks, being gross feeders, like a rich soil, and their full beauty cannot be ensured unless the ground has been deeply trenched and plenty of manure worked into it. When well grown they rank amongst the most stately of autumn-flowering plants, and certainly no good garden ought to be without them; but what is the fact? I have visited many good gardens and large gardens—gardens in which there was no lack of means to purchase all the plants that might be thought necessary for every purpose, but there were no Hollyhocks. Fashion seems to have selected Sunflowers for the place once occupied by Hollyhocks. Sunflowers that used to nod their heavy heads in cottage gardens are now sought after by people of high degree. Owing to the neglect into which Hollyhocks have thus fallen, there is now some difficulty in obtaining them, and when one does obtain them the chances are that we get

DISEASED PLANTS. Ours were supposed to be free from disease, but it could be seen in a virulent form on them even in midwinter. It was useless to throw the plants away, for I did not know where to look for healthy ones. The plan I adopted, however, seems to have been so far successful, as now, when the plants are growing freely, they do not show any trace of fungus. Every leaf that had any upon it was pinched off and burned, and the plants were dipped in a strong solution of soapy water, into which a considerable quantity of flowers of sulphur was mixed. I carefully watched them every day for many weeks; during that time the disease did re-appear on them, but the instant a fungus spot was apparent on any of the leaves they were picked off and destroyed. In one or two cases the plants were almost defoliated. At intervals the remaining leaves were soaked in the soap and sulphur mixture. We shall be careful in future in introducing any fresh plants into our collection, and if the disease is fortunately stamped out, we are not likely to be troubled with it again, as there are no Hollyhocks, clean or unclean, anywhere near us. While the air remains cool there is not much danger from

RED SPIDER, but when hot, dry weather sets in this pest is likely to get troublesome, and unless it is destroyed the leaves assume a brownish, rusty colour, which will prevent the development of well-formed flowers. This pest is destroyed by soapy and sulphur water, or it may be kept in check by frequent syringings with clean rain water. Mulching the ground round the plants is also beneficial. See that the flower-stems are tied to the sticks as they increase in growth, which will prevent them from being injured by high winds. This is a good time to

SOW SEEDS of Hollyhocks. They may either be sown on a piece of fine soil out-of-doors or in pots and boxes in a frame. In the latter case the young plants ought to be pricked out as soon as the first rough leaf is formed. They should be cultivated in the open ground during summer and be planted out where they are to flower in September; by planting them at that time the plants become established before winter, and unless the latter is an exceptionally bad one they seldom sustain injury; indeed, few are killed by either frost or wet.

J. DOUGLAS.

IBERIS GIBALTARICA HYBRIDA.

THE finely flowered and singularly charming plants of this new hybrid *Iberis* shown at South Kensington the other day by Mr. Dean could hardly fail to direct attention to its merits not only as a hardy perennial, but also as a decorative pot plant. The plants in question were in 6-inch pots, and were about 9 inches in height and literally masses of bloom, the trusses being about midway between those of the little grown and somewhat coarse habited *gibraltarica* and the better known *superba*. The individual blooms were large, and, though opening white, soon deepen to a soft peach or lovely rosy lilac hue. Though grown in pots and kept in a frame for the winter, the plants shown had been in the open air for several weeks past, so their true habit and colour were clearly indicated. This new *Iberis* was raised by the late Mr. Nelson, of Aldborough. It is not believed, however, to have been an artificially obtained hybrid, but seems to have been a chance seedling, having *gibraltarica* for its seed parent, with, it is assumed, the dwarf growing biennial *Tenoreana* for its pollen parent. What is certainly remarkable is, that whilst neither of these kinds are specially hardy, some of the forms of the new hybrid are very hardy, though others, and particularly those which seem to follow after *Tenoreana*, die freely both outdoors and under glass, chiefly, it is believed, from damp. Mr. W. Thompson, of Ipswich, who has sent out from time to time so many beautiful additions to our

his attempts to produce anything good from hybrids have been absolute failures. Whatever he has produced of value has been produced by sheer accident, and in nearly every instance from common seeds sown in the nursery beds or nursery rows. This is depressing enough, but in the very next note on the same page (p. 296) it is reassuring to read that some of the finest of American fruits have been raised from the seeds of native or common types fertilised with pollen of superior varieties. After reading that note from the *Prairie Farmer* about Mr. Robert Douglas's failures we thought of what Knight, Rivers, Dominy, Seden, Court, Denny, Laxton, and half a hundred others of our own hybridists had done for us, and we pitied the man who so frankly acknowledges therein that Dame Nature had beaten him. She beats all who do not understand her—all who disagree with her; but then what a reward she has in store always for those who with knowledge help and assist her in her work!

MECONOPSIS NEPALENSIS is just at this season one of the most stately and effective of all hardy plants in flower. No other flower I know has such softness in the pale yellow of its petals, and their delicate satin-like lustre is made yet more effective and conspicuous by the tassel of rich orange anthers which tremble within the cup-shaped blooms. Even as a fine-leaved plant of distinct and noble port, this Nepaulese Poppy well deserves culture, but as a flowering plant it also is quite unique. Raised from seeds in the spring, the young plants are fit for planting out in June or July, and the strongest flower during the year following. *M. Wallichii*, with blue flowers, is not so common, and *M. simplicifolia*, with its large nodding solitary blue flower, is still more rare in our gardens.

THE ORRIS ROOT, OR FLORENTINE IRIS, a mass of glaucous sword-like leaves and great soft lilac flowers, is just now a fit companion to the crimson and rosy-flowered Pæonies, the Tulips and Pansies of this early summer-tide. Even the common German Iris is a beautiful object when well grown either on the Grass or on the open borders among Solomon's Seal and nodding Bluebells, also among the many pink and flesh-coloured and white varieties of the latter which are just now among the freshest and most graceful of all hardy bulbous plants. Purple Honesty and golden Wallflowers make quite a show of themselves, but of all our hardy flowers none please us more at this season than do the great clumps of Florentine Iris, bearing, as they do, such noble broad-petalled flowers.

PLANTS FOR ROOMS.—One of the very best and most satisfactory of room plants is the evergreen *Aspidistra lurida* and its white striped variety, but perhaps, all things considered, the green-leaved variety is hardiest and best. I have seen specimens recently having from twenty to thirty leaves which had been grown in windows for the past seven or eight years. Water occasionally and sponging when the leaves become dusty is all the attention this plant requires. *Cyrtomium falcatum* is one of the best of all room Ferns, and as a distinct and effective window plant none are finer than *Aralia Sieboldii* when laden with its seven-lobed digitate leaves, but nothing can be finer or give less trouble than the *Aspidistra*, or Parlour Palm. In Holland, I am told that the last named and Siebold's *Aralia* are amongst the most generally grown of all window or room plants, and to my mind they are far preferable to the ephemeral subjects too often used as domestic ornaments.

THE TIME OF IRIS BLOSSOMS.—Now that the Daffodils are well-nigh gone, and the Tulips are on the wane, what grace and variety of colour the many-hued Irises bring to our gardens. The Spanish and English bulbous kinds (*Xiphion*) are spearing up their swollen stems eloquent with promise of bud and flower. Iris sibirica has its elegantly pencilled blooms poised like butterflies on the slenderest of wand-like stalks, and *I. nudi-*

caulis, *I. pumila*, with many others are now gay in the sunshine, but of all the Irises we look forward with some anxiety to the blooming of the *I. lævigata* or *I. Kämpferi* race, which promise us flowers as large as *Clematis lanuginosa*, and of the most startling diversity in form and colour. Hearing of these being submerged in marshy or bog beds in Japanese gardens, we planted some in a border near the pond, where, after being under water most of the winter, they are now most strong and vigorous.

CHOICE BORDER PLANTS.—We have a plant flowering here now which is to almost all our visitors a stranger. It is a rosy-flowered form of the old Leather Columbine (*Thalictrum aquilegifolium*) growing 2 feet to 3 feet in height, each stem being crowned by a terminal corymb of rosy lilac finely fringed. White and yellow varieties of *Thalictrum* are common enough, but as rosy ones are rare, this one the better deserves notice. Another plant not at all too abundant is the vivid scarlet-flowered *Ourisia coccinea*, a plant of dwarf and compact habit, and worthy of the most careful culture. Those who have it not should note it as a "good thing." That the pure white *Anemone sylvestris*, the vivid Oriental Poppies, double-flowered *Narcissus poeticus*, and plenty of late blooming Tulips should be grown in quantity wherever borders are devoted to hardy flowers goes without saying, but just now for effect the Pæonies and Irises and *Anemones* blazing in the sunshine bear away the palm.

CHOICE WALL SHRUBS.—"What curious blue-flowered shrub is that on your wall?" is quite an everyday question, and the blue-flowered shrub is *Solanum crispum*, or, as "F. W. B." would no doubt call it, the Potato Tree. Quite near it the wall is rosy with the dense rosy clusters of *Spiræa bella*, and the white-flowered mountain *Clematis* (*C. montana*) hangs its white starred wreaths over the old grey stones. Here *Clematis alpina* is a mass of deep green leaflets, studded with its soft blue bells, and there the lilac spikes, or panicles rather, of *Veronica Hulseana* are tossing in the breeze at the foot of a warm wall. Tiny Banksian Roses nestle among their waxy foliage, and already ere June comes does our old Gloire de Dijon give us a foretaste of that sweet time of Roses which is to be. Broad masses of golden-leaved Ivy are now at their freshest and best. *Choisya ternata* and *Vella Pseudocytisus* alike add beauty to our wall drapery. VERONICA.

FRUIT GARDEN.

GOLDEN QUEEN GRAPE.

I HARDLY understand what "W. W. H." wishes to imply in his remarks (p. 404) respecting this Grape. I do not say that it is destitute of good qualities, but I do say that it is never likely to take a high rank amongst Grapes. I grant that it is a good grower and fruitful and that it sets well, but it requires very careful ventilation to keep the foliage in good condition; nor is its colour in any way pleasing, for unless the bunches are exposed well to the light during the later stages of ripening they assume a dingy brown hue, and the berries have a very poorly defined transparency that does not add to their appearance. Moreover, the sugary, unrefreshing character of the flesh is not likely to gain for them many admirers. All this I regret, because as regards matters of cultivation, if the foliage is kept right, I have nothing to say against it. It is certainly distinct; it has glaucous foliage and a peculiarly shaped berry which no one can fail to recognise. In a word, I may say that it is what I call "a gardener's Grape," by which I mean it is not a difficult variety to cultivate. It is sure to show plenty of bunches, and the berries set thickly without involving any of the trouble that belongs to the Muscats, and it will ripen in a temperature intermediate between that which suits Hamburgs and Muscats. Moreover, it is a fairly good keeper.—J. C. CLARKE.

Small-flowered Peaches for forcing.—"W. W. H." (p. 469) wishes to know the points by which I consider Dr. Hogg Peach and Lord Napier Nectarine are superior to the kinds he enumerates for early forcing. As he desires the term (early forcing) not to be misunderstood, I will fix the date for the fruit to be ripe—about the 15th of May—which will, I think, be quite within range of the usual acceptance of the term. 1st, I prefer Dr. Hogg Peach for its uniformity in size of fruit; and 2nd, for its great solidity, which renders it most valuable if required to be sent a long distance, especially by rail. As to Lord Napier Nectarine, its quality generally, and for forcing especially, it simply has no equal.—MR. WESTCOTT, *Raby Castle Gardens, Darlington.*

Grape nomenclature.—Will Mr. McIndoe, of Hutton Hall, be so good as to furnish the history of the white Grape shown in his collection at Manchester, and named Early Smyrna Frontignan. I cannot find the name of it in my edition of the "Fruit Manual," in "Vines and Vine Culture," or in the "Gardener's Assistant." To me and others who saw it, but did not taste it, it looked as like the Royal Muscadine as two Peas, only not quite so large in the bunch, and if it possessed the Frontignan flavour, I would have said it was the White Frontignan, such as I have seen exhibited at the same society's show by Mr. Tegg, late of Clumber, and which has many synonyms. I see by a report of the show that the Grape shown by Mr. McIndoe is described as being "the best early white Grape in cultivation," but I have an impression it is either the one or the other of the above old acquaintances, and which can be determined by the flavour.—J. S. W.

Small-flowered Peaches the best.—"W. W. H." has done right in calling attention to this, and it will be well to bear his words in mind. He says small-flowered varieties are the best for forcing, but I would go a step further and say that small-flowered Peaches and Nectarines are much the surest fruiters at all seasons and in all situations. I have seen many instances in cool houses, and in the open air too, where all the trees were completely clothed with bloom, but while the large flowering ones did not form a full crop or require any to be thinned, the small flowering ones formed many more than were required. I have been told by others that the same thing occurs frequently with them; in fact, it is the rule; and I am of opinion that fine full crops of Peaches and Nectarines would be much oftener secured if the greatest attention was devoted to small flowered varieties.—J. MUIR.

Fruit prospects.—After the effects of the past spring on Peaches and Apricots (the latter mostly), the subject as to the best protective material for fruit trees is again brought before our notice. Whether it is desirable to wire walls for these tender fruit instead of nailing seems to be an open question, but these are two important points in connection with the culture of fruit trees against open walls. As the season is near at hand when we shall be having the annual report of the fruit crop, I would like to ask those who contribute to it if they would note the kind of protection used in spring, and if the trees are nailed to the walls, or the walls wired. The neighbourhood they write from, too, is important to know in order to be of real value. In this garden we have but a thin crop of Apricots, and these are on shoots close to the wall; not one is to be found only in that position. The walls are nailed and covered with thick blinds. This induces me to think that wiring in our case would have been a mistake.—J. C., *Farnboro', Hants.*

Mouldy Strawberries (W. H. T.).—I believe the white powdery matter on your Strawberries is, as you suppose, a fungus, but so little was left on the fruit that I cannot be quite certain. Some fungi are as fond of dryness as others are of moisture. Are your plants kept too dry and without sufficient ventilation? Strawberry plants should always have moisture and plenty of fresh air.—G. S. S.

PLANTS IN FLOWER.

LITTONIA MODESTA.—As a cool house climber this is very effective. It is a Liliaceous plant, nearly allied to *Gloriosa*, and during the winter is kept in a dormant state, but with the return of spring its growth is rapid, and at the present time the pretty golden yellow bell-shaped flowers are expanded. In flower at Kew.

LILAC CHARLES X.—Dotted here and there in the shrubberies at Kew this Lilac stands out prominently from all others by reason of the deep rich hue of its blossoms and the massive clusters in which they are borne. Though there are now an almost endless variety of sorts, this is still one of the best of its class.

DOLICHOS LIGNOSUS is not only a pretty, but a most distinct greenhouse climber. It is a free-growing plant, producing Pea-shaped flowers in dense clusters. When first expanded, they are of a bright rose colour, but afterwards change to mauve. It helps to enliven the roof of the conservatory (No. 4) at Kew in a charming way.

CENTAUREA MONTANA RUBRA.—A bright and pretty variety, with tassel-like flowers 3 inches across of a pleasing rosy pink colour. It is, no doubt, as compact and neat in growth as the typical form, which is one of the most useful hardy border flowers we have in May. Messrs. Backhouse, of York, send us some fine blooms of it.

HABROTHAMNUS NEWELLI has brighter flowers than those of the well-known *H. fasciculatus*, and are borne in long pendulous clusters, which give the plant a very graceful appearance. It is now in flower in the temperate house at Kew. It is an excellent plant for adorning a back wall, rafter, or pillar in a conservatory or any other cool house.

GREENLAND POPPIES (*Papaver nudicaule*), in yellow, white, and orange-red colours, are sent to us by Mr. Kingsmill from his garden at Eastcott. The cup-like form of the flowers is handsome, and their bright and varied colours make them most important flowers in the open-air garden at this season, particularly when grown so fine as they are in the Eastcott and Munstead gardens.

DRACAENA BANKSI.—Although this is generally grown for the sake of its foliage, it is a very pretty object when in flower, in which condition it may be seen in the temperate house at Kew. A couple of shoots about 4 feet or 5 feet high have each produced from its upper part a large branching spike, which is studded with small pure white flowers, the whole having a light and elegant effect.

SARMIENTA REPENS.—This pretty little creeping Chilean plant produces in great profusion urn-shaped flowers of a bright scarlet colour, bearing some general resemblance to those of *Mitraria coccinea*. It delights in a peaty soil in a cool and moist situation with plenty of drainage. In a cool house at Kew a couple of plants suspended in shallow pans are just now very attractively in bloom.

RANUNCULUS REPENS FL.-PL.—The double creeping Crowfoot is really a pretty plant, having button-like flowers as double as possible and of a bright yellow. Mr. Wolley Dod sends us flowers of it, and remarks that it grows about a foot high, and is twice as floriferous as *R. acris*. The flowers remind one of miniatures of the florist's *Ranunculus*. It does not appear to be much known, for we seldom meet with it.

BLANDFORDIA FLAMMEA ELEGANS.—Among desirable, but neglected, plants must be included the *Blandfordias*, which are seldom seen in gardens, yet when in flower they are really handsome. One of the most showy is the above-named, which from a tuft of Grass-like foliage throws up a scape about 2 feet high, terminated by a cluster of a dozen pendent flowers, each from 2½ inches to 3 inches long, funnel-shaped, and bright crimson in colour, with yellow tips to the petals. These plants are natives of Australia, although the one under notice is said to be a garden hybrid. All

require a soil composed partly of peat, good drainage, and copious supplies of water when growing. We noticed this splendid variety in Mr. Bull's nursery at Chelsea, where several of its allies, particularly *B. princeps*, were rapidly throwing up blossoms.

ANTHURIUM ANDREANUM.—An exceptionally fine spathe of this plant is sent us by Messrs. Heath from their nursery at Cheltenham. It measures 6½ inches in length by 5½ inches in breadth, and the form is more rounded than usual. Messrs. Heath state that the plant from which this was cut has six of such large spathes as that sent; it must be a fine specimen.

PRIMULA SIKKIMENSIS.—Very large and graceful heads of this stately and beautiful Primrose come to us from Messrs. Backhouse at York, no doubt gathered from one of the snug and shady nooks in the unique rock garden in the nursery. The unusually fine growth indicates that it finds a congenial home there, and we should like to hear from Mr. Potter the conditions under which the plants are growing.

SCILLA FRASERI, best likened to a small form of the North American Quamash (*Camassia esculenta*), is really a pretty plant, graceful in form and extremely delicate in colour. The flowers are produced in a long, dense spike, terminating a stem from 1 foot to 2 feet high, and are of a soft mauve tint, a colour not seen in any other hardy bulbous plant in gardens. It comes well grown from Mr. Kingsmill's garden.

RUBUS DELICIOSUS.—This Rocky Mountain species is a very handsome spring-flowering shrub either as a wall plant or when allowed to assume its natural habit of a dense bush. Examples of both styles of growing it are to be seen at Kew. It is a spineless species, with three or five-lobed (not pinnate) leaves, and pure white flowers about 2 inches in diameter, produced in great profusion from the axils of the leaves. During the week we have received some elegant sprays of this plant from Messrs. Backhouse, a certain proof that it thrives well at York.

PROSTANTHERA LASIANTHOS.—The delicate markings of the flowers of this plant would compare with many Orchids both for strangeness and beauty. It is of shrubby habit, belonging to the Labiate family. The flowers, about an inch in diameter and pure white, are covered with hairs, and the interior of the throat is freckled with violet. It is a native of Australia, and may be seen in flower in the temperate house at Kew.

MESPILOT SMITHI, also known as *M. grandiflora*, is one of the most handsome flowering trees to be seen at Kew at the present time. On the lawn at the back of the Palm house is a specimen about 20 feet high. In general aspect it resembles a large Thorn, and the whole tree is thickly studded with pure, white flowers, each over an inch across. For gardens where moderate-sized trees are desirable this handsome Medlar should be taken note of.

CROSSANDRA UNDULÆFOLIA is an Acanthad of easy culture, producing numerous flowers arranged in terminal spikes, and of a reddish orange colour. The peculiar hue of the blossoms renders it very distinct from most of its associates, and with its free habit of growth marks it as a desirable subject for the stove or intermediate house. It is now in flower in one of the stoves at Kew. We have also met with it under the name of *C. infundibuliformis*.

HYBRID AZALEAS.—The old Azalea beds at Kew are just now a gorgeous sight, and well repay a visit. Such a show of bloom is seldom seen, and the situation surrounded by greenery shows the gay colours to the best advantage. The Azaleas occupy several beds on the right of the Sion vista in one of the openings of the wood. It is strange that these Ghent Azaleas are not more frequently planted, as they seem to do well almost anywhere, provided it be not in too dry a situation or in a limestone soil. At Kew they are planted on some rising ground, the soil there being a kind of stiff loam, which has been mixed

with a liberal quantity of decayed leaf mould, and in this the plants flourish admirably. Among the best kinds in flower we noted *Exquisite*, deep yellow; *albicans*, white, bluish tinge; *luteo-rubicunda*, pink and yellow; *Empereur*, yellow; *multiflora*, bluish; *vitellina*, deep orange; *elegantissima*, orange-crimson; *alba*, pure white; *Ne Plus Ultra*, bright crimson; *mirabilis*, rose; *insignis*, bright rose; *pardina*, orange and rose; *grandidissima*, large orange; *mutabilis*, cream and rose; *carnea*, flesh. Close by are some *Azalea mollis*, well showing the wide range of colour already obtained among them, and proving worthy rivals to the best of the older kinds.

PAPAVER UMBROSUM.—Of this brilliant annual Poppy, Mr. Wolley Dod sends some fine blooms cut from stems 2 feet high. The flowers are some 3 inches across, handsomely cup-shaped and of an intensely deep crimson, with large and conspicuous jet black blotches at the base of each petal. Those who do not know this showy hardy flower should make its acquaintance, for it makes the garden very cheerful just now with its masses of glowing colour.

MAGNOLIA ACUMINATA AND CORDATA.—Close to the hardy Azaleas at Kew these two Magnolias are in flower; the first is the Cucumber tree of America, being a young, vigorous, bluntly pyramidal tree with, however, smaller foliage than is frequently the case with this kind. The flowers are a sort of greenish yellow, and though interesting do not add much to the beauty of the tree. The other (*M. cordata*) is smaller in all respects, but bears a great general resemblance to the *M. acuminata*.

ASTER PEREGRINUS.—Under this name we have received from the York Nurseries an extremely pretty flower nearly 2 inches across, having numerous narrow ray florets of a delicate mauve and a large yellow disk. We do not remember having seen it before. Messrs. Backhouse also send the large *St. Bruno's Lily* (*Anthericum Liliastrium*), *Phlox subulata atropurpurea*, a dark variety, *Iberis Pruiti* with dense heads of white bloom, and *Trollius japonicus* with bright orange flowers.

PELARGONIUM GLOIRE DE NANCY.—New and distinct varieties of Pelargoniums still come to the fore, among them being this one which belongs to the Ivy-leaved section in Mr. Bull's nursery at Chelsea; it is conspicuous among a host of others on account of the bright hue and large size of its blossoms. It is one of the sturdy, free-growing varieties, bright cerise-red in colour, the whole flower being shaded with violet. Like most of the best belonging to this section, it is of Continental origin.

ERYSIMUM RHETICUM is a bright yellow alpine plant, forming dense tufts, which at this season are densely studded with clusters of blossoms, which help to enliven the rock garden at this season. Some flowers from Messrs. Backhouse show how well it thrives in the rock garden at the York Nurseries. They also send flowers of *Alyssum alpestre*, a very neat little plant of dwarf tufted growth. It is also studded with bright yellow blossoms at the present time. Both should be taken note of by lovers of alpine flowers.

CRINODENDRON HOOKERIANUM.—Of this singularly beautiful Chilean plant a coloured plate was given in *THE GARDEN* some time ago, and it may now be seen in flower in the temperate house at Kew. From the small size of the specimen there it would appear to be remarkably floriferous. The flowers are globose, about the size of a Filbert Nut, of a deep rich crimson. We notice that its name has been changed to *Tricuspidaria hexapetala*, but no doubt Messrs. Veitch will still continue to distribute it under its better-known original name.

PHYLLOCACTUS FLOWERS from Mr. Peacock's fine Cactus collection at Sudbury House, Hammersmith, remind us of a bright and showy race of plants, but comparatively neglected. All the *Phyllocacti* are more or less showy flowered plants, but the kinds Mr. Peacock sends are particularly so. These are *P. Ackermannii*, *Jenkinsii*, and mul-

tiflorus, all with large crimson flowers, abundantly produced even on small plants, and especially so in the case of *P. multiflorus*. The other species sent is *P. phyllanthoides*, differing from the rest in having smaller flowers of a deep rosy pink. All these are capital plants for the greenhouse, and their flowering season extends over several weeks. They are, moreover, particularly suitable for window culture, and some of the finest plants we have seen of *P. multiflorus* have been grown in a cottage window. It would be a step in advance if the promoters of flower shows would offer prizes for a dozen of the best and most useful ornamental Cacti and such like plants out of the ordinary run of "flower show" plants.

DODECATHEON INTEGRIFOLIUM, one of the North American Shooting Stars, is one of the prettiest plants in the open-air garden at the present time. On erect flower-stems, about 6 inches high, it carries an umbel of about a dozen blooms of a rich magenta colour, with centres of bright yellow. This is one of the best and highest coloured of the Dodecatheons, and a plant that, owing to its being easy to grow, should be found in every country garden. Some fine flowers reach us from the York Nurseries.

LILIUM ELEGANS GUTTATUM.—Under this name we noticed a very pretty and distinct Lily in flower at Mr. Bull's nursery. The individual blooms were comparatively large, borne erect, as in the elegans or Thunbergianum section, and orange-red in colour, with a brighter hue towards the base of the petals, but the peculiarity consisted in the whole flower being profusely and regularly dotted with deep maroon spots. Such a handsome Lily cannot fail to become popular when better known. It is particularly beautiful when grown in pots for flowering in a greenhouse in May.

RHODODENDRON SESTERIANUM.—Some extremely fine trusses of this beautiful hybrid variety are sent us by Mr. Smith, of Guernsey, who says that it flourishes admirably there in the open air. The flowers are 4 inches across, pure white, except faint flushings of rosy pink on the exterior of the corolla. They, moreover, emit a delicious perfume. On one small forked branch there are as many as fifteen of these large blossoms, a sufficient proof that it thrives well with Mr. Smith. The rosy pink unexpanded buds remind us strongly of those of the grand *R. Aucklandi*.

AQUILEGIA GLANDULOSA.—Flowers of the true form of this Columbine come to us by post in excellent condition all the way from Mr. Wolley Dod's garden at Edge Hall, Cheshire, a remarkable fact seeing that Columbines are among the worst flowers to travel when cut. The true *A. glandulosa* is indeed a lovely plant, having large blossoms of a bright violet-purple tipped with white. Accompanying these flowers are others of the true Canadian Columbine (*A. canadensis*), also a beautiful plant with red flowers, and a few bicolorous forms of the common *A. vulgaris*, all distinct and pretty.

WEIGELA ABEL CARRIERE.—The adaptability of the Weigela for covering walls or fences of moderate height is well shown at the present time in Mr. Bull's nursery, where a quantity of this beautiful variety has been utilised for the purpose, and the plants are now a mass of bloom, the hot, sunny position having apparently induced unusual floriferousness. This variety is the best of the rose-coloured kinds that has come under our observation, the flowers being larger and of more substance than in the better-known rosea. It was sent out from the Continent some four or five years ago, but does not yet seem to be much known.

EREMURUS AT BELGROVE.—The handsome, pure white-flowered Himalayan species of *Eremurus* is now blooming beautifully in my garden, one of the plants for the third and the other for the first time, though both of them are exactly of the same age and came from the same batch of seedlings. This plant seems to be perfectly hardy as I have never given it any kind of protection even during the severe winters of 1879-80-81. It has

also the advantage over its more robust growing and larger flowered relative, *E. robustus*, from Turkestan, of starting to grow considerably later in the spring, and so escaping the continued wet and other inclemencies of the months of January and February in our moist climate. My strong plant of the last named fine variety growing in centre of bed between its two Himalayan brethren, which bloomed so finely in summer of 1881 on a stem nearly 8 feet in height, has not since flowered, the growth commencing early in January, and the flower-spike rotting while still down in the undeveloped leaves from the continued rain lodging around it. I hope by some means to prevent this next year.—W. E. G.

AZALEA ROSEIFLORA.—The finest specimen we have ever seen of this Japanese shrub, one of the most charming plants we know, was shown by Messrs. Backhouse, of York, at the South Kensington show last week. The plant, in a pot about a foot in diameter, was a large, dense bush over 2 feet across, and fairly smothered with its double rosetted blossoms of a lovely salmon-pink colour. The plant was the admiration of everyone, being so pretty and so distinct from other Azaleas, or, indeed, any other plant at the show. Few had any idea that the plant could be grown so large, for hitherto it had only been seen in London in a small state. Messrs. Backhouse were appropriately awarded a cultural commendation for the plant.

BLUEBELLS FROM A LONDON GARDEN.—I send a few Scillas from under the trees in my garden. Their lovely colours and graceful habit of growth make them a charming sight. They grow very freely, and with Ferns, Funkias, and other such things, the wilder parts of my garden are just now very gay, and yet with a wealth of soft greenery that sets off the pure colours of the Scillas.—STUART WORTLEY (Col.), *Rosslyn House, Grove End Road*. [A pretty and interesting gathering, including, we should imagine, every shade of tint existing in Scilla nutans and *S. campanulata*. The whites and pinks are extremely pretty, and there are some of a delicate porcelain blue.]

EURUBIA GUNNI.—A long slender shoot of this Australian shrubby Aster from Messrs. Veitch's Coombe Wood Nursery indicates that the plant finds a congenial home there—no doubt against a snug and sunny wall. The specimen is pretty, being wreathed with white blossoms as large as Daisies. It is, we believe, the hardiest of the Eurubias. The musk-scented species, *E. argophylla*, is a plant worth trying against a warm sunny wall. Another species, *E. ilicifolia*, from New Zealand, is a branching, habited shrub with white flowers freely produced, and much in the way of the better-known *E. Haasti*, but are larger and more open. It is now in flower against the herbaceous ground wall at Kew.

THE SPANISH BROOM (*Genista hispanica*) is among the showiest and best dwarf shrubs one can have to enliven the garden in May. It is neat in growth, its maximum height seldom exceeding a yard, and it invariably forms a symmetrical dense bush which for two or three weeks about this season is a complete mass of golden yellow blossoms, brighter even than the double Gorse. Its place is in open spots on the margins of shrubberies where it can get plenty of light and sun, and it is also a capital plant for bold rockwork, as it does not intrude upon its near neighbours, as do many other dwarf shrubs. A fine branch of it laden with bloom comes from Messrs. Veitch's nursery at Coombe Wood, and is one of the finest hardy shrubs we have seen this season.

THE SPECIMEN MARGUERITES shown at South Kensington last week by Lord Londesborough's gardener (Mr. McPherson) from Northwoods, Hants, thoroughly deserved the medal awarded, as they were by far the finest Marguerites that have been shown at least in London. The pair were both enormous plants with symmetrical Mushroom-shaped heads, some 5 feet in diameter, and so profusely furnished with large Ox-eye Daisy-like flowers as to be like dense masses of white. The species seemed to be *Chrysanthemum Halleri*, not the *C. frutescens* which has been

shown hitherto in large specimens. It certainly needed skilful culture to bring these plants to the show in such a perfect condition. Being such an unusual feature, they attracted as much, or more, attention than all the huge specimen plants of the ordinary "stove and greenhouse stamp" that make their annual round of the big London shows.

STEPHANOTIS FLORIBUNDA.—Two glorious wreaths of this favourite stove climber reach us from Mr. Carter, gardener at Downhill, Coleraine. Each shoot is about a foot long, and is completely covered with flower clusters, some numbering as many as ten in a bunch. The chaste beauty of the waxy flowers and the strong perfume make this plant so deservedly popular. Mr. Carter says his specimen is planted out in a stove, and the whole plant is covered with bloom after the manner of the shoots he sends.

INDIAN AZALEAS OUT-OF-DOORS.—I send you some blooms cut from plants that have withstood the last two winters unprotected the single white blooms are from a plant fully exposed in a bed of peat with Ghent Azaleas. The coloured ones are more sheltered and planted in natural decayed leaf mould, which seems to suit them well. We have fifty of them planted out, and they present a most striking appearance, having an unusual brightness about them very distinct from other flowers in the open air.—T. T., *Creech Grange Wareham*. [Very good blooms indeed; scarcely, if at all, inferior to those produced under glass, being large and highly coloured.]

THE PEACOCK IRIS (*J. Pavonia*) is sent us in great beauty by Mr. Smith from his Caledonia Nursery, Guernsey. It is a sweetly pretty flower, not much like an ordinary Iris in form, as the broad petals stand out almost horizontal. The colour of the petals is white or suffused with a faint purplish tint, but the chief beauty of the flower is the rich blotch of sky blue at the base of each broad petal, which, in contrast to the white, is very charming. The Peacock Iris seems to luxuriate in Guernsey, and no doubt in the open air; whereas to grow it well here we must give it the protection of a greenhouse or frame, though we have seen it thrive in snug corners in some places, and notably in the gardens at Redleaf. Though the flowers last only for a day, the spathes carry several flower-buds, which open in quick succession. It is a plant that everyone would be pleased with when in bloom, and is worth a little trouble to cultivate.

NEW PLANTS shown by Mr. B. S. Williams last week at the floral committee meeting included *Cattleya Mossie Alexandre*, one of the loveliest varieties we have seen, having large finely-made flowers of a delicate rose-pink; *Cycas elegantissima*, a truly elegant Cycad with long gracefully arching pinnate leaves; *Dieffenbachia gigantea*, a new variety of great promise as an ornamental foliaged plant; *Croton musaicus* and *Masterpiece*, two new and handsome additions to the long list of fine-leaved Crotons; *Odontoglossum marmoratum*, with large well-formed flowers heavily spotted and suffused with rosy purple, a most beautiful variety; the rare *Dendrobium rhodopterygium*, like a small edition of *D. macrophyllum*, and therefore less showy; *Aralia Kerchovi* and *Amaryllis Crimson Banner*, an extremely handsome variety, remarkable for the brilliant crimson colour of the blossoms extending to the very centre, leaving not the slightest trace of light colour in the throat, an unusual occurrence in *Amaryllises*. The flowers are not very large, but are of firm texture and admirably formed. We regard it as one of the finest of *Amaryllises* yet produced, and a fit companion to the Dr. Masters variety, also an admirable one.

Diseased Gloxinias.—Why do the leaves and buds of my Gloxinias turn brown just when the flower-buds have formed? This is the third year such has been the case; before then I had beautiful flowers. I was told they wanted a light, airy shelf; but this made no difference. I have seen to the drainage being perfect. It is certainly not from a dry atmosphere.—J. S. D. [The leaves

you send are badly infested with the small yellow thrips, which have probably been the cause of the mischief. The best plan would be to burn the plants so infested, thoroughly cleanse the house, and start next season with either new bulbs or with seedlings raised during the present year.—A. S.]

PARIS FLOWER SHOW.

THE show of the Société d'Horticulture de France, which closed on Monday last, took place, as in the past two seasons, in the Pavillon de la Ville de Paris, behind the Champs Elysées Palace. The inside of the pavilion was devoted to hothouse plants, Palms, Ferns, Orchids, Gloxinias; also to Rhododendrons, Azaleas, &c., all tastefully arranged. At the back of the pavilion was a long, wide tent containing Clematises, annual plants, Roses, hardy plants. On the side of the pavilion was again another tent for standard Rose trees and vegetables. The area round the pavilion was admirably arranged as a garden, and at the rear was the show of horticultural implements. This is altogether a most convenient place for holding shows, standing as it does in the centre of the Champs Elysées, in the most fashionable part of Paris. It is easily approached by long and very wide roads on all sides, so convenient for carriage traffic. The show ground is surrounded by avenues of Chestnut trees, which afford a delightful promenade.

The first thing that struck us in the pavillon was a long bed of Gloxinias, from M. Vallerand; some were named sorts and the other seedlings were all very fine. The flowers were enormous; we noted Cecile Michaux, pure white; Jupiter, dark violet; Neptune, violet; and A. de Rothschild, white flower, with the margins spotted with pink. On the right were several groups shown by M. A. Chantin, the grand prize being taken by his Palms, Ferns, Aroids, but the same plants are exhibited year after year, so that we begin to know them. What was more interesting to us was his group of Orchids, Bromeliads, and new plants, amongst which we noted the following: Eucharior Saundersi, roseum, Guzmania tricolor, Disteganthus scarlatinus, Nidularium spectabile, fulgens, Streptocalyx Vallerandi, Canistrum viride, Billbergia Chantini horrida, Tillandsia muscica, tessellata, Lindeni, Barilleti, Cycas Terkesi, madagascarensis, Pritchardia Vuystelkiana, Dracena Massangeana, Begonia diadema, Heliconia aureo-striata, and various others.

Orchids were shown in quantity, though not as a rule remarkable for high quality; when the plant was fine the flowers were poor, and vice versa. For example, Masdevallia ignea, Veitchi, and others were shown with one flower, and very few of the rest would have been seen in England even at an ordinary show. M. Chantin had in his group a good and choice selection as regards species and varieties. On the other side of M. Chantin's groups were the exhibits of M. Truffaut, of Versailles, which consisted of a very fine group of miscellaneous hothouse plants, including Bromeliads, Palms, and Orchids. The following were most prominent: Lycaste Skinneri, aromatica, Cypripedium caudatum, Dayanum, barbatum, levigatum, Harrisianum, villosum, insigne, Sedeni, Cattleya Trianae, intermedia, Mossiae, Skinneri Saccolabium ampullaceum, Masdevallia ignea, Odontoglossum Pescatorei, vexillarium, Roczi, Alexandræ; Miltonia spectabilis, well flowered; Dendrobium nobile, Oncidium crispum, concolor, Weltoni, Chysis bracteata, Trichopilia coccinea, &c. On the same stage were Messrs. Thibaut and Keteleer's Orchids, including Cypripedium levigatum, caudatum, ciliolare, nevium, Hookeri, &c., Cattleya amethystina, Regnelli, &c.; Oncidium Weltoni, concolor, Odontoglossum Pescatorei, Phalenopsis, Rossi, Cervantesi, Vanda tricolor, Masdevallia ignea, Veitchiana, Harryana, Brassia guttata, and a good plant of the new Pitcher, Nepenthes Mastersi, well coloured. M. Bleu, the Caladium raiser, had over a hundred varieties of his well-known plants, amongst which stood l'Automne, a new plant lately figured in the *Revue Horticole*, and also a few Cattleyas. Mons. Croux had a good show, including a

group of Rhododendron Michael Waterer in splendid condition, with a border of Kalmia myrtifolia all round and well bloomed, also a grand group of Rhododendrons of the best varieties, well flowered; Joseph Whitworth, Baron L. de Rothschild, M^{me}. Emile Boyan, M^{me}. Masson, fine white; Sir Henry Mildmay, Alarm, Pelopidas, Mrs. Holford, Crown Prince, Helen Waterer, very fine colour; Matchless, Lady Eleanor Cathcart, &c., &c. The same firm had some good Indian and Caucasian Azaleas—Rosetta, bluish; Fama, pink; Pallas, pink and yellow; Coccinea grandiflora; Triomphe de Royghem, yellow; Mazzeppa superba, white. Conifers and Acers also from this firm were to be found outside. M. Christen, of Versailles, showed as usual a good lot of Clematis, varied and in good condition, so did also M. Georges Boucher, of Paris. M. Constant Lemoine, of Angers, had a very fine and striking lot of Dracenas, all of his own seedlings, well marked, and of good specimens. M. Paillet showed a collection of Conifers, hardy Magnolias, Hollies, Rhododendrons, Indian Azaleas, and the new Prunus Pissardi, with its very dark red foliage.

We found also in the pavilion some big specimen Roses, such as are exhibited in London by Messrs. Turner, Paul, &c., but in quality they certainly did not come up to the English plants, but it shows that the French are taking a lesson from English cultivators. M. Margottin fils was the exhibitor; he showed also Vines in pots with fruits and standard Roses. Among other prominent exhibitors of the Rose were M^{ms}. Levêque & Son and M. Charles Verdier. M. Vilmorin-Andrieux & Co. had, as usual, a fine show or annuals, including Calceolarias, Cinerarias, &c. M. E. André had a lot of his novelties, which he showed well; and M^{ms}. Chantier frères, of Morte-fontaine, had a good group of Crotons of their own seedlings besides new plants; this lot was extremely well arranged, and contained an Anthurium Andreanum with many flowers and a very fine Leea amabilis, one of the handsomest fine-foliaged plants. The show was good and well arranged, thanks to the energy of the president of the show committee, M. Joly, assisted by his secretary, M. Eugène Delamarre.

At the banquet offered by the society to the members of the jury we were told by the president, M. Lavallée, that it was the intention of the society to hold a grand international exhibition in Paris in 1885, the exact date to be fixed hereafter. English nurserymen and amateurs, get ready!

CORRESPONDENT.

PUBLIC GARDENS:

RICHMOND PARK.

If there is no connection now between the Corporation of London and Richmond Park, there was once a very real connection, for in 1649 the House of Commons resolved that the park should be given in perpetuity to the City, to be preserved as a park, and so remain, as a mark of the favour of Parliament, and it was accepted. At the restoration of Charles the Second, however, the Corporation returned the park to the king, with the assurance that they had held it for him only as his stewards. So much is set forth shortly by the late Mr. James Thorn in his pleasant work on the environs of London, and it may be found in other books and documents. Henceforth the standard work, however, will be a handsome quarto volume, which has just appeared, and which, published by the authority of the Corporation, has been edited by Sir Thomas J. Nelson, the City solicitor. Here is given a full history of the transaction from the records of the House of Commons and of the City, together with an interesting description of the park as it is now, from the pen of the City solicitor. The park was given to the City in June, 1649, a few days after Cromwell, at the invitation of the Lord Mayor and Common Council, honoured the City at dinner, in the Grocers' Hall, after attending, with his principal officers, the Council of State, &c., a

public thanksgiving service, on the establishment of the Commonwealth, at Christ Church, Newgate Street. Between 1641 and 1660 a good many notices appeared in the Corporation records of payments in respect of the park. Soon after the death of Cromwell, however, the Commonwealth beginning to show signs of dissolution, and things appearing ripe for the restoration of monarchy, Charles the Second wrote letters from Breda to, among others, the Corporation, whereupon the latter sent a deputation the the Hague carrying with them a substantial proof of the City's loyalty in the shape of £12,000, as also the restoration of the park, with which the king was so pleased, that he conferred the honour of knighthood upon all the members of the deputation.—*City Press*.

A park for North London.—A correspondent in the *Times* writes: It has always seemed to me that as from time to time the question of securing spaces for suburban parks arises, one spot in the north-west of London has always been overlooked—I mean Caen Wood. It is obvious that in the event of that property falling into the hands of the builder, not only would Hampstead and Highgate be robbed of their chief sylvan beauty, but the sanitary loss to the whole of London would be irreparable. The heights extending from Hampstead to Highgate practically dominate the whole of London. Let the public acquire Alexandra Park as well, if possible, for the benefit of the northern suburbs; but with regard to London as a whole, there can be no doubt that Caen Wood and the fields between it and Kentish Town would, with Hampstead Heath, form the most important "lung" of the metropolis.

THE Rev. Canon Hole has been appointed one of the chaplains to the Archbishop of Canterbury.

Pelargonium sport.—I enclose flower of Pelargonium showing red and white flowers on one flower-stalk. Is not this an unusual occurrence?—E. A. W. (It is unusual, but the variety you send, which is Vesuvius, is particularly liable to sport. In a sort called New Life there are the two colours in the same flower.)

Tabernaemontana Camassa.—Why does this plant every year lose its buds? I have never yet had a flower out.—J. S. D. (Judging by the specimens you send, the plant is subjected to too low a temperature. It requires a hot and moist stove in order to succeed well. If the conditions of heat and moisture are given, the plant is easy to manage.—T. R.)

Clematises drooping (W. S. B.).—Judging by what you send, we should say that the injury to the leaves of your Clematis is the result of hot sun on them while wet, for they look as if they had been scorched. There seems to be no trace of insects or fungi. The plant will probably recover in course of time, though it is somewhat crippled for the present season.

Grubs (B.).—The grubs are those of the daddy-long-legs or crane fly (*Tipula oleracea*). They are very injurious to the roots of various plants, and are often most destructive to lawns. They may be caught by burying pieces of Potatoes, Turnips, &c., attached to skewers or small pieces of stick. These traps should be examined every morning, as the grubs often come to the surface during the night; rolling the ground at that time would kill them. Trenches 6 inches wide and 6 inches deep with upright sides will catch numbers of them; they fall in during their nocturnal ramblings, and cannot escape. They should be collected in the morning.—G. S. S.

Names of plants.—*J. R. Boyd*.—*Franciscea confertiflora*.—*G. Nisbet*.—Orchid leaf is from a species of *Dendrobium*, probably *D. chrysotoxum*; the flower is *Dendrobium snavissimum*.—*G. Potts*.—Double Poet's Narcissus (*Narcissus poeticus* fl.-pl.); a common plant, grown largely for market.—*C. M. O.*—*Spirea hypericifolia* (variety); *Berberis Hookeri*; *Sedum Aizoon*; apparently *Saxifraga aquatica* (a pretty plant).—*M. & Co.*—Your plant is the true *Begonia semperflorens*.—*A. G.*—In order to name the Forget-me-nots we must see larger specimens and sent so as to be received here fresh. Send in a tin box or in oiled paper or oil-skin, but with no cotton wool.—*C. A.*—A singular fusion of several flowers which we do not remember having seen before.—*E. Molyneux*.—*Cerasus Padus* (Bird Cherry)

"This is an Art

Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES.

EXPOSURE OR SHADE.—There is some perplexing evidence respecting sunshine and shade in our gardens, but I am convinced that all plants worship the sun if other conditions are suitable to them. "Well," says an old friend, "try Filmy Ferns in the sunshine, and note the results;" and I may agree with him that they are notable exceptions, although I know two pans of Killamey Fern which are magnificent examples of fine growth, and yet they stand on a vinery floor fully exposed to air and light, if not a little early morning sunshine as well. In deep, rich soils, or where moisture lies below the surface ready to be attracted by the drier soil above, nearly all plants do better in sun than in shade. In Holland Mr. Burbidge tells me he saw hundreds of acres of Lily of the Valley growing in flat, sandy fields in the full sun, and this may account for these Dutch clumps flowering so well; but even at home, where many gardeners grow their own Valley Lilies for forcing, they are planted out in the open quarters with the best results. This brings us to the point of my argument, viz., that the position in which plants are naturally found is not necessarily the best one in which to grow them for our own particular uses. Many plants fail to grow in full sunshine simply because they are too dry at the root; planted beside a wet ditch, no sunshine would kill them. Here lies buried the secret of tropical luxuriance—great heat and much moisture.

PACKING CUT FLOWERS.—During a year I receive some hundreds of boxes of flowers from all parts of Europe, and in seven cases out of ten these flowers are completely ruined by being packed in dry cotton wool. Of all packing material for delicate blossoms it is the worst I know. The best is clean fresh wood Moss (*Hypnum*), and a little tissue paper may be wrapped around each flower when large, or around the clusters or bunches when small. If Moss be not to hand, then soft green leaves are preferable to cotton wool, or the good flowers may be carefully arranged among commoner ones without any other packing except a wet newspaper; better still, blotting paper at top and bottom of the box or basket. Nearly all flowers are better cut in the bud stage just before opening. So cut they pack more firmly and travel more securely than when fully expanded, and thus give far more satisfaction on their arrival. The buds of Daffodils, Irises, Water Lilies, Roses, Gladioli, Tulips, Poppies, &c., never carry safely unless packed in some moist Moss or fresh leaves and in the bud stage.

SUMMER WINDFLOWERS.—Will any lover of fair flowers tell us aught of *Anemone alba*, which is said by a friend to be of a dwarfer and more vigorous habit than *A. sylvestris*, with a larger, erect, cup-shaped bloom nearly 3 inches across? *A. dichotoma* is now very pretty with us, a foot in height, bearing several flowers, each the size of a shilling, in an irregular sort of umbel above the radiate involucreal leaves. I am not sure that *A. dichotoma* is the right name, but I know the plant is tolerably uncommon, since but few of our visitors recognise it as it grows here, spreading over a border in full sunshine. Beside it *A. Pulsatilla* is now bearing aloft its tufts of Clematis-like seeds, and *A. palmata* (yellow) recently gave us of its richest gold. I wish some of my friends now on the Pyrenees would send to THE GARDEN Office seeds or roots of *A. sulphurea*. Then those beautiful wild *Anemones* of Greece should not be forgotten by all who visit the German explorations and excavations at Olympia. The name and the noble beauty of all Windflowers is Greek in character, but why called Windflowers? Doctors differ.

PLANTAIN LILIES.—A little damp plot of soil in a partially shaded place planted with a collection of Funkias is now a pleasant sight. One or two of the bold golden variegated kinds are very effective, so is *F. Sieboldi*, but all are fine-leaved plants of the best, and that they luxuriate beneath trees or among dwarf shrubs is another point in their favour. Quite by accident some seedlings of the Japan Primrose (*P. japonica*) were planted among these clumps last year, and they are now in full bloom, the whorls of purplish crimson flowers peeping up near the great soft leaves being most effective.

THE SATIN LEAF.—I have often wondered why the North American *Heuchera Richardsoni* (*H. ribifolia* of some gardens, and *H. americana* of others) is not more generally grown for the sake of its rich brown satin-like leaves. There are but few stove plants that can rival its rich delicacy of colour and leaf texture, and that the foliage endures for several weeks fresh and fair after being cut from the plant is a great advantage not to be overlooked. I placed half-a-dozen of its leaves in a Bohemian vase the other day and put a spike or two of *Primula sikkimensis* in among them and the effect was—well, no hothouse productions could have been more admired or more wondered at, for neither the Sikkim Cowslip nor the Satin Leaf have as yet attained that familiarity which is said to breed contempt.

THE SATIN FLOWER.—Can any of the readers of THE GARDEN inform me when or where this name was first applied to *Sisyrinchium grandiflorum*? Will "Rho" kindly enlighten us? I am anxious to know because the other day I was amusing myself by collating my two copies of Parkinson's "*Paradisus Terrestris*" (1st ed., 1629, and 2nd ed., 1656), and in the latter edition I find he has two Satin Flowers, the one our white Honesty, and the other a Leguminous plant—perhaps our French Honeysuckle (*Hedysarum coronarium*). Of the first, or Honesty, Parkinson saith, "It hath divers names as well in English as in Latine, for it is called most usually Bolbonach and *Viola lunaris*; of some *Viola latifolia*, and of others *Viola peregrina*, and *Lunaria græca*, *Lunaria major*, and *Lunaria odorata*, and is thought to be *Thlaspi cratene*. In English White Satten, or Satten flower; of some it is called Honesty or Penny Flower."

THE VERNAL SQUILL.—I saw a very pretty wild garden the other day and enjoyed its luxuriant freshness and beauty. Mossy turf was spreading itself like a green carpet over the grey rocks, and the whole garden was a hillside slope, a thousand acres or so, its outer edge touching the cliffs, which hang over the sea at a height of 200 feet or 300 feet. Gorse made the hill-top golden, and the blue *Scilla verna* shone among the young Grass blades like stray bits of turquoise among many emeralds. Broad breadths of *Silene maritima* hung here and there on the grey rocks, and for contrast *Geranium sanguineum* was flowering among the loose stones, and where former glacial rocks had ploughed deep gullies down the hillside, thus leaving broad ravines or chins down to the sea, the young Brake Fern fronds were thickest and most thoroughly at home. But there was a jewel in the turf that the black-faced mountain sheep had browsed down until it was smooth and even—a little starry blue flower in patches here half an acre, there a rod or two, now in groups a yard across, and now almost solitary, but always fresh and lovely. It strayed about the sunny hillside like a blue-eyed child at play, now up quite near to the prickly Furze, now on the fringe of the little bogs where Sundews and Grass of Parnassus are at home; and of all the hillside flowers the fairest is this *Scilla verna*.

THE GARDEN OF PLEASANT FLOWERS.—An old work on garden flowers, Parkinson's "*Paradisus*," is not met with so often as it deserves to be. I wonder no one has reprinted it, and someday I shall ask Mr. Daydon Jackson's opinion on that point. It is of all the old English works on gardening

the best and most original, and even now it is looked after by dealers in second-hand books, a tolerably good copy fetching at least £2 or £3. His descriptions of Narcissi, Anemones, Roses, indeed of most of the hardy flowers now so popular, are of the quaintest and most characteristic kind, and no one can study his book without being surprised at his knowledge of the plants commonly grown in English gardens so soon after Shakespeare's epoch (1629). This work is to the flower garden what Evelyn's "*Sylva*" is to forestry, and it is not too much to say that no garden library is complete without a copy or a reprint of Parkinson's "*Paradisus Terrestris*;" or, the Garden of Pleasant Flowers."

FLOWER COLOURS.—Mr. Grant Allen has told us that flowers were all originally yellow, and that other colours came as a sort of development of the original plan induced perhaps by climatic changes, perhaps fostered by insect visitation. I know that the mountain-tops of the world, or the higher zones of flowering plants, do offer us many yellow-flowered species; but the question is, are we to take these as the remnants of the race primeval? Insects are certainly less frequent on the mountains than in the plains. Hence one cause of colour variation is thus removed, and yet, notwithstanding this, we have a good many of those exceptions which are said to prove the rule. The flowers of *Cheiranthus mutabilis* open yellow and change to dull red; but what are we to learn from *Muscari moschatum flavum* which is reddish purple in bud, but the flowers change into soft wax-like yellow? The more we read of flower colour or of insect agency, the more chaotic does the subject appear; it is so difficult to see through the misty border-land of science, and the question of flower colour and its origin seems to me as yet "not proven."

CATLEYA MOSSLÆ.—A friend who has just been making a little tour in Ireland tells me of a remarkable specimen of this grand old Orchid—a good variety also—now bearing thirty-nine fully expanded flowers in one of the hothouses at Straffan. It is a veritable specimen, well grown, perfect in shape, every leaf perfect, and a great contrast to the "made-up" specimens we now and then see at exhibitions. In the same collection *Disa grandiflora superba* and *D. Barrelli* are growing like weeds in one corner of a house filled with herbaceous Calceolarias. The door stands open quite near to them night and day, but dryness is counteracted by copious syringings. In a few weeks' time they will be well worth seeing, the flower-spikes being both many and vigorous. *Oncidium macranthum* var. *hastiferum* is also blooming in the Straffan collection, its flowers nearly 4 inches across. The purple lip in shape reminds one of a fox's head, and contrasts well with the broad golden petals.

HARDY PLANTS IN FLOWER.—The Edelweiss is now bright and characteristic, each plant studded with its silvery stars. A seedling or two planted on the top of a wall, along with *Erinus alpinus*, is now very pretty and finer in colour than the larger inflorescence produced by plants in the ordinary borders. *Linaria pallida* is worth making a note of by those who have it not; and so also is *Ourisia coccinea*, with its bright green cortusa-like foliage and erect spikes of vivid scarlet tubular Pentstemon-like flowers. *Aquilegias* of the finer kinds are now lovely in the warm breeze, and will for the future be kept up by imported seeds, as no reliance can be placed on seeds saved where many species and hybrids are grown in company. The great spires of the French white Rocket are most pure and fragrant in the gloaming; like the favourite Marvel of Peru of the Persians, this white Rocket is best and most to be enjoyed at eventide.

A RARE WINDFLOWER.—In that same moist and sheltered rock garden, in a spot a little more elevated than that occupied by the tall Poppies of Wales, past a big mass of *Lastrea cristata*, and

near to where *Soldanellas* grow in masses over a foot across (with leaves nearly as large as those of *Cyclamen Comm.*), past these there is a clump of the rare *Narcissus Bernardi* in flower; *N. muticus*, from the Pyrenean meadows, has but just faded, and the great broad fronds of *Onoclea sensibilis* vie with those of the deep green Holly Fern (*Aspidium Lonchitis*) in strength and vigour. Past all these there are great umbels of what look at first sight like snow-white Buttercups swaying in the breeze. It is a clump of *Anemone narcissiflora*, a plant far more common in books than in gardens, but a great beauty, quite an aristocrat in its own way, bearing eight or ten stout dowering stems towering up 15 inches to 18 inches in height above its finely cut leaves. This Windflower is a great beauty. Close by the speckled trout are fly hunting in the river, and the young herons chatter high up in the tall Spruce Firs as they eat their dinner. Poor flies and ye speckled trout, beware of that long sharp bill!

*

THE TIME OF POPPIES.—Having raised many Poppies from seed during the past two years, we now are reaping a good harvest of "buried hopes." Poppies give a brilliancy, a summer-like aspect to the garden quite as characteristic in its way as is the autumnal "tone" of Dahlias, Sunflowers, and *Sedum Fabaria*. Who will tell us the distinction between *Papaver orientale* and *P. bracteatum*? *P. umbrosum* true seems to be a fine variety of *P. Rhæas* with greenish pollen. *P. caucasicum* forms a mass of pale glaucous leaves, and its soft pale salmon-red flowers are much admired, and of native "weeds" one of the prettiest is *Meconopsis cambrica*, or Welsh Poppy, which thoroughly enjoys a deep rich cool soil and some little tree shade. I saw it the other day, 3 feet or more in height, among some big clumps of *Struthiopteris germanica*, that reminded one of *Dicksonia antarctica*. But of all the Poppies give me the alpine and Icelandic forms of *P. nudicaule*, and especially those of the Munstead strain or race.

VERONICA.

FERNS.

BEST CULTIVATED FERNS.

(Continued from p. 487.)

DICKSONIA.—Of the several arborescent kinds forming the very interesting group known as Tree Ferns, those belonging to this, probably the least extensive genus, are the most effective as well as the most manageable. They all require cool treatment, coming, as nearly all of them do, from New Zealand and Australia, where they are found growing in valleys and in deep shaded ravines, and where they occasionally find their fronds heavily loaded with snow. *Dicksonia antarctica* especially grows in great abundance on Mount Wellington, in Tasmania, where it is often subjected to a much cooler temperature than the one under which it is usually kept in cultivation, and I believe thrives very well planted outside in sheltered spots in different parts of England, Wales, and Ireland. Wherever a favourable spot exists Tree Ferns should be made use of, as they present a peculiarly beautiful and magnificent tropical appearance by their singular contrast with hardy exotic as well as with native ornamental trees. All *Dicksonias* are strong growers and their immense trunks possess the great advantage of being generally of good proportions and of symmetrical habit; they are besides much more fibrous than most of the other Tree Ferns, thus storing up a much greater quantity of moisture and retaining it for a much longer period fit for the natural and essential requirements of growth, and at the same time necessitating less labour than *Cyatheas*, *Cibotium*, &c.; whilst in other genera may be seen stems of all dimensions, even down to that of an ordinary walking-stick, the stems of *Dicksonia* are all of moderate thickness. They also have the advantage of producing much handsomer heads than any other Tree Ferns, and as a rule the quantity of fronds is proportionate to

the bulk of the stem, and it is not at all rare to find stems of good dimensions producing every year from thirty to forty fronds, which they generally retain until the development of the new set, that is, if they do not suffer from want of water during the winter season; for, although they are at rest, still their fronds will soon shrivel up if their stems are allowed to get dry. When grown in pots it is indispensable that water should be freely applied to the roots all the year round, or they will show the effects of one day's neglect in an unmistakable way, and it will take a very long time for them to recover the damage done during that short time; they are all the more likely to suffer from want of water when grown in pots, as these should be of the smallest size possible, according to the sizes of the stems. As a rule, all Tree Ferns do best when potted in pots or tubs, allowing only 2 inches or 3 inches of soil all round the stem. The compost should be a mixture of two parts rough fibrous peat and one of loam, with a proportion of coarse silver sand. However good their growth may be in pots, it cannot equal the vigour of the plants grown in the open ground, in which case the bottom must be particularly well drained, so that the roots may not be rotted by stagnant moisture. To produce luxuriant foliage *Dicksonias* should during the summer have their stems thoroughly well watered twice a day, but these copious waterings should gradually decrease as the season advances, and during the winter the stems should only be kept moist, the heads being lightly shaded during the warmest days only.

D. ANTARCTICA.—This evergreen temperate species from New Zealand, though now the most common of the arborescent kinds in cultivation, is universally admired; its magnificent stem varies considerably in thickness, which, however, is generally in proportion to its height. Although it is said to attain the height of 30 feet or more, the most handsome specimens that one generally meets with measure from 12 feet to 18 feet high, and the spread of their magnificent fronds is from 15 feet to 22 feet. They rise from a hairy crown, are lanceolate in shape, tripinnate and rigid in some specimens, whereas in others they are beautifully pendulous; their under surface is of a light, almost glaucous, green, while their upper surface is of a rich shining dark green. It is admirably adapted for all sorts of decorations on account of the hardness of its constitution, and the marvellous symmetry of its stem and crown of fronds. Greenhouse.

D. ARBORESCENS.—A very fine evergreen arborescent kind found only in the island of St. Helena, and which is still very rare in cultivation. The stem has a peculiarly ragged appearance, for although growing only from 8 feet to 12 feet high, it is generally found with several branches terminated by a crown, each densely clothed with amber coloured silky hairs. The fronds, which are bipinnate with very obtuse pinnules, grow from 5 feet to 6 feet long; they are leathery in texture, light green in colour, and borne on stalks very tomentose; the general habit of the plant is very elegant. Greenhouse.

D. BERTEROANA.—This fine species from Juan Fernandez has a special interest, as being one of the few plants indigenous only to that remarkable island and that we have in cultivation. It is a strong growing kind, with stalks and fronds thicker and stouter than those of any other *Dicksonia*. The stem is of drier substance than that of most of the other species belonging to the same genus; it reaches 7 feet or 8 feet high, and from its dark brown hairy crown a tuft of arching fronds spread gracefully in all directions. These attain the length of 7 feet, and are proportionally very broad, tripinnate, and coriaceous in texture. The pinnules have rounded lobes overlapping each other, producing quite a massive appearance. In its young state the plant is also of elegant and symmetrical habit, although it only begins to show its really beautiful characters when it is about 2 feet high. These characters as above described render it one of the most pleasing conservatory or greenhouse Ferns, among which, on account of its firm and durable texture, it retains its verdant ap-

pearance for an indefinite period, the plant being generally in possession of all its old fronds when the young growths make their appearance in the spring. Greenhouse.

D. CHRYSOTRICHIA.—A very handsome species from Java of recent introduction. Its stem, of moderate thickness, is clothed all over with dark brown, very brittle roots descending from the crown, which is also of the same colour and produces long and gracefully arching, almost pendulous fronds from 6 feet to 7 feet long; the base of their stalks is abundantly covered with short bristly brown hairs which remain on them after their development. The fronds, of a somewhat ovate-lanceolate form, are bipinnate and finely cut with pinnæ 12 inches to 18 inches long and 6 inches to 9 inches broad; the pinnules, rather loosely set, give the whole plant a charmingly light appearance. It probably is found at a great elevation in its native country, as it is found to succeed best under cultivation in a cool greenhouse.

D. FIBROSA.—This fine New Zealand species, which is seldom met with in cultivation, at first sight somewhat resembles *D. antarctica*, from which it seems to be only a variation. It is, however, essentially different and readily distinguished from it by its stem, which is much stouter in proportion to its height, and by its broader and shorter fronds of a dark shining green, and the pinnules of which are turned upwards at the ends, thus giving the whole of the plant a bristly and rigid appearance. The stems attain large dimensions, sometimes reaching 15 feet or more in height; it is very fibrous, being all covered with small wiry roots, which, instead of descending straight from the crown as in other species, seem to intercross each other all over the stem. Greenhouse.

D. SQUARROSA.—A very handsome New Zealand species, particularly attractive on account of its slender, black stem, often found branching by its forming young plants, produced at intervals up the trunk. The habit of the head is beautiful and very effective; it is quite flat and tabulariform, and formed of a quantity of rigid fronds, dark shining green on their upper surface, paler beneath; they are tripinnate, 6 feet to 7 feet long, and finely cut with pinnules, acute and closely set; the stalks are black and hairy. It is altogether a most distinct, very elegant, and choice Fern, and one whose appearance is totally different from any other of the same class. The stem, being of a very dry nature, must be carefully kept constantly moist. Greenhouse.

D. YOUNGLE.—This species, native of New South Wales, somewhat resembles the preceding, but the stem, which is not black as in *D. squarrosa*, is more slender; the stalks are of a bright light brown—a very effective colour; moreover the fronds, produced more sparingly, are broader, more massive, and less lanceolate in shape. Instead of forming a flat head they are pendulous and more elegant; they are also of quite a different texture, and of a cheerful light green. Greenhouse.

PELLÆA.

The fernery at The Wilderness, Reading.—Singularly bright and cheerful are the varied tints of green seen in the new fronds of the wondrous collection of hardy Ferns in this garden. Mr. Lees has not only fashioned from out the midst of a dense mass of shrubs an extensive fernery, but by the aid of gigantic boulders, the setting into position of which must have been an herculean task, has given to this fernery an air of reality that is far too uncommon in such matters. A more interesting or better grown collection of hardy Ferns it would be difficult to find growing under similar conditions, and the lover of these charming plants might revel for hours in the contemplation of beauties to which those ignorant of Ferns are strangers. It is worthy of notice that in heat or shade, and there is little of the latter, the plants thrive equally well. Attempts to cover the smooth surfaces of the huge stones with plants have been successful only in the cases of *Ivies* and that singularly effective creeping shrub, *Cotoneaster*

repens, which is one of the very best things to be found for the purpose. The growth is exceedingly ductile, and follows alike cavity and prominence, clinging to the stone without adhering with singularly good effect. This plant has flowered freely, and now is being well set with berries. Mr. Lees has removed all his alpine plants which formerly occupied a portion of the fernery to a rockery specially provided for their reception, and the collection has been largely enriched by additions from Tottenham and elsewhere. Nooks of this kind are very pleasing when dropped upon unexpectedly, and something more interesting than a dense mass of Laurels or other shrubs. Moreover, they enable myriads of hardy plants to be cultivated that could not exist in shrubbery borders or other unsuitable places.—A. D.

Drymoglossum piloselloides.—In the review of the book "Indian Ferns" the writer, speaking of this Fern, says he has never seen or heard of it being in any collection. We have some beautiful specimens of this rare species growing luxuriantly on cork in our nursery, and we have had them several years in our collection. We shall be pleased to show these to anyone.—W. & J. BIRKENHEAD, Sale, near Manchester.

TREES AND SHRUBS.

NORDMANN'S SILVER FIR.

(*PICEA NORDMANNIANA*.)

THIS Silver Fir, introduced into this country about the year 1845, has not only proved perfectly hardy, but likewise capable of accommodating itself to a great variety of soils and situations; and I think I am not exaggerating when I say that it is one of the best trees not only for ornament, but for general utility, to be found among the many fine species in the section to which it belongs. It is indigenous to the Crimean Mountains, where it attains an average height of about 100 feet. As a specimen tree on a lawn it can scarcely be surpassed, its handsome, regular, conical shape and rich dark green foliage rendering it an object of great beauty, and even when planted in cold, bleak situations it never fails to attract attention. It likes the full blaze of the morning and noon-day sun, and is a valuable tree for planting in cold, deep valleys in the immediate vicinity of water, places in which I have seen the Larch, common Silver Fir, and even the Oak severely seared, yet this tree stood on the same ground quite uninjured. As regards

SOIL, it is not in the least degree fastidious; in fact some of the finest trees I have ever seen of this species I planted upwards of twenty years ago on well decomposed peat bog, with which a little soil was mixed at the time of planting. When planted on ordinary soils, however, it seems to prefer such as contain a liberal mixture of organic matter, resting upon an open subsoil, thoroughly drained. In places where the subsoil consists of hard gravel or stiff argillaceous clay this Fir makes decidedly less progress; therefore, under such circumstances it is necessary to have the ground thoroughly prepared by trenching and breaking up the hard crust, and in places where it is desirable to plant for ornament if a little bog earth is mixed with such soils at the time of planting, it will prove to be of great use in promoting the healthy development of the trees. It is

PROPAGATED principally from seed; young trees, however, generally produce cones a few years before any male flowers make their appearance, and even when the latter do appear they only come in limited quantities, and not in proportion to the number of cones on the tree. As the trees advance in age and size this deficiency becomes less marked. In the meantime in cases in which it is desirable to propagate this Fir—and it is well worthy of being propagated—the pollen may be collected and economised by applying it to the canes artificially. Thus when the catkins which contain it are ripe and ready to burst, it should be carefully shaken out on a sheet of clean paper and immediately applied to the cones with a small pencil brush. In order to fertilise them—an operation easily

accomplished—when the tips of the scales reflex which they do at a certain stage, insert the pollen, and when once fecundation has taken place the scales gradually close inwards of their own accord, thus rendering the interior of the cones impervious to wet. I have generally fertilised this Fir between the hours of ten and twelve o'clock in the forenoon. If necessary the pollen of one tree can be applied to the cones of another of the same species with perfect success. The fertilised cones should be collected in autumn and the seeds extracted from them and sown in spring. It is seldom this tree produces

DOUBLE LEADERS, but when such is the case, my practice has been to disbud or cut the weaker of the two clean off with a sharp knife in spring, and by autumn the wound so produced will be completely healed up. On the whole I anticipate a grand future for this tree, and from what I have seen of it I have every reason to believe that in a few years' time it will be planted extensively not only as an ornamental tree, but also as a forest tree. Young trees which I have cut up show the timber to be of a very high order indeed, the concentric rings being firmly packed, clean, and resinous. J. B. WEBSTER.

THE DECIDUOUS CYPRESS.

(*TAXODIUM DISTICHUM*.)

THIS tree is extensively distributed in parks and gardens throughout Britain, but chiefly in the south of England, where fair specimens may occasionally be met with, notably in the Duke of Northumberland's grounds at Syon House, Brentford. It was introduced into England from Virginia prior to 1640 by Tradescant. When young the tree is pyramidal in form, with slender, tapering branchlets, but when old it has a broad Cedar-like head and its branches are characterised by abrupt angular bends. It attains an enormous diameter, exceeding even that of the Wellingtonia. In Florida and Louisiana stems are frequently met with 40 feet in circumference above the enlarged base, the buttressed base itself measuring three or four times that size. The roots of large trees, especially in moist situations, send up conical or bee-hive shaped excrescences or knees, as they are called. These are often 3 feet or 4 feet in height, and rise to the surface from a depth of 6 feet or 8 feet when the tree is grown in a submerged soil. They are always hollow and frequently used in their native country to make bee-hives. The large buttresses of this tree are carried to an excessive extent, the base being generally three times the circumference of any other part of the trunk, and often hollow for about half of its bulk—a character made use of by Moore in his "Lake of the Dismal Swamp," viz., "I'll hide the maid in a Cypress tree when the footstep of death is near."

THE TIMBER is very durable, even under water, and is finely grained and of a reddish colour. A peculiar property of the wood is its adaptability to split straight, so as to serve for planks without the use of a saw. To cultivate this tree successfully it must have good, rich soil, a well sheltered situation and abundance of moisture, not stagnant, which is probably the reason why a sandstone district is preferred, a chalk soil being too dry, and a clay subsoil defective in drainage. The tree is readily propagated from cuttings or seeds, of which latter a good supply is regularly imported from America. It is never planted for profit, but only as an ornamental tree for park or lawn decoration.

THE MEXICAN SPECIES (*T. Montezumæ*) differs chiefly in the less size, deeper green and more slender and tapering character of its twigs and leaves as well as more tender constitution. It also attains a greater size than the foregoing, the famous specimen at Santa Maria del Tule, in Oaxaca, being no less than 200 feet in circumference. Near the city of Mexico are two immense trees of this kind, one of which, at Chapultepec, measures over 90 feet in circumference near its base. This species is rarely met with of any size in England, being too tender for our climate generally.

A. D. WEBSTER.

Ornamental Acers.—Both at Gunnersbury Park and The Wilderness, Reading, may be seen richly-coloured examples of the purple cut-leaved Acer—very striking objects in the shrubberies. In the latter place a fine pyramidal bush of the variegated Dogwood is very handsome, and specially beautiful is the Fern-leaved Beech, a rare tree, and, as seen in The Wilderness grounds, singularly handsome. This latter tree, a high-coloured purple Beech, and a yellow-flowered *Favia* make together a very effective trio.—A. D.

Pyrus Malus floribunda.—Among deciduous shrubs now in bloom none are more showy and beautiful than this *Pyrus*, crowded as it is with delicately-tinted pink and white blossoms that hang in long sprays on the gracefully curving branches, which seem to be quite borne down under their load. For planting as single specimens in conspicuous places on lawns, this *Pyrus* is quite unrivalled. The best way when used for this purpose is to have standards with tall clear stems, as in this form it displays its pendulous habit, and shows off its blossoms to the greatest advantage. Grown among dwarf shrubs, with the heads standing clear out, this *Pyrus* is also exceedingly effective, as are likewise bushes of it in the foreground of evergreens, where it associates well with its congener *P. japonica*, and also with *Berberis Darwinii* and *stenophylla*, all of which are glowing with colour, and a most lovely and pleasing contrast they make.—S. D.

FRUIT GARDEN.

VINES AND TOP-HEATING.

THE more I see of Grape growing in my visits to good gardens the more am I satisfied that there is very much more to be said in favour of the introduction of heat near to the Vines than is generally assumed. When some time ago I made an observation to that effect in these pages quite a storm of opposition was raised, and, as is invariably the case, the discussion ran off into side issues, and there it ended. No doubt "Peregrine" or some other well-known Grape grower will have something to say in reference to this subject again, but whosoever may do so, I trust they will stick closely to the point of discussion—that is, the relation of top-heating to Grape growing—and will do so more in a spirit of practical enquiry than with a desire to show that I or anyone else must be wrong. There are, I know, not a few vineries in the kingdom in which the plan of top-heating may be said to be partially in operation. These are houses that, being low in elevation, have of necessity the front pipes at least brought into close contiguity to the Vines. We find this specially to be the case in many market vineries, and I have particularly remarked that such is the case in the low houses in which Mr. Wm. Cole, of Feltham, grows his Muscats, than which none better are taken into Covent Garden Market. I have in these houses observed that all his best sets and earliest and finest bunches are always those just over the pipes, which are not more than 18 inches from the Vines, and, indeed, I have seen bunches actually touching the pipes, and apparently liking the heat. But recently I visited the vineries at Chalfont Park, Slough, where Mr. Herrin, a young, but able Grape grower, is getting some capital fruit, and specially was I struck with the grand show of Muscats he had just over his pipes; in fact, the lower third of the Vines showed better results than any other part of the house. It may be that top-heating, or any such method of top-heating as would bring the pipes into close contiguity to the Vines all over the roof, would be more useful in the culture of Muscats than of any other Grapes, although we shall probably be told that as fine Muscats are grown as a rule in lofty houses as are ever seen in low houses. At Maiden Erleigh, near Reading, again, there is to be seen very similar results in the several vineries where Mr. Turton is producing some grand bunches of various kinds, and I think it is very probable that Mr. Wildsmith will not deny that in his low span house devoted to the culture

of Lady Downes he has obtained his best finished bunches from close to the pipes. I admit that these are but few instances, but those of the readers of *THE GARDEN* who have been favoured with greater opportunities for observation than I have been may be able to adduce similar ones in abundance. I make no suggestion as to how a system of top-heating of houses of any kind may be best applied. We know something of Mr. Cannell's system, and which, in spite of the opposition of hot-water doctors, is a first-rate system for winter use, and is being largely adopted. The same kind of thing, if it be possible, is well worthy of trial in Grape culture, and it is just possible may prove as successful. No doubt I shall be met on the threshold of the discussion with the pessimist obstruction, "we get plenty of good Grapes now, and what more do you want?" Perhaps so, but at what cost, and with how much trouble and labour? Can better results be obtained more cheaply by top-heating, or can they not? The subject is of interest to Grape growers, and merits intelligent consideration. A. D.

Price of Tomatoes.—In the note (p. 482) on this subject it is mentioned that the price of Tomatoes in London is 4s. per pound, a statement at which I am greatly surprised, for I am a large Tomato grower and am unable to sell my fruit at half the money. It proves the great disadvantage growers are under in not being able to supply the public direct. The middle men must be making an enormous profit.—**FRUIT GROWER, Ridgeway, Malvern.** [With this note the writer sends a sample of his early Tomatoes, which are excellent in every respect.]

Fruits of Persia.—Concerning these M. Bernay writes as follows in the "Bulletin de la Société d'Acclimatation": Azerbaijan, where I reside, is one of the most fertile portions of Persia. The fruits which grow there are delicious; we have Peaches as large as those of Montreuil and more highly perfumed, but the Grapes are especially remarkable, notably one called Askery, the berry of which is of moderate dimensions, white, sugary, perfumed, and without seeds; moreover, the skin is so thin that one can hardly taste it. Another variety is distinguished by the great size of the berries, which are very sugary and have a thick skin. The bunches of this Grape come to an enormous size. M. Bernay states that he intends sending cuttings of these Grapes to Europe, and it is to be hoped that he will succeed in so doing, as they might prove to be valuable acquisitions.—J. C. B.

The fruit crop.—I am sorry to say that "the promise of May" will not be fulfilled as far as the fruit crop is concerned in this district. With the exception of Apples, most kinds of fruit will be below the average, and Nuts appear to be almost a total failure. Bush fruits in some parts are bearing fairly well, but both Gooseberries and Currants have "run" lately. Plums, with the exception of the Victoria, which seems a perpetual bearer, will be a very short crop, and of Damsons we have very few indeed, the usually prolific Farleigh Damson being conspicuous by its absence. Cherries blossomed well, but during the last week much of their fruit has disappeared. The Apple crops promise to be very large, although, like other kinds, they have suffered from the late cold nights. Pears in orchards, with a few exceptions, will be scarce. Reports from many districts have been so good, that I should like to hear how fruits are looking now.—L. A. K., *Maldstone.*

Market fruits.—A very despondent forecast is made in West Middlesex as to the nature of the fruit crops in market orchards for the coming season. Apples seem to be so far the only top crop that has any considerable degree of promise, for they seem to be set abundantly, although not proportionate to the wondrous bloom seen on the trees recently. Still a fair crop of Apples really means a good crop, because the fruit is finer and pays better than when it is so very plentiful. However, very heavy crops of any kind of fruits are now so uncommon, that

growers will have no objection to one that seems to be great now and then. Pears bloomed so freely that a good crop might well have been anticipated. Really, however, there will be but a miserable crop, for the bloom has not set, and the fruit germs have fallen wholesale. Plums, too, are thin, and Cherries of the better kinds will not be plentiful. The greatest complaints are, however, made over the Gooseberries, which in many large gardens have proved to be almost a failure, in spite of the fact that they were thickly set with bloom, and the fruit germs seemed to be safe at first. Presently, however, they fell and all at once, so that in many places the bushes are quite stripped. Currants promise to be fairly plentiful; so also do Raspberries and Strawberries. So large is the extent of Gooseberries grown and so much are they relied upon to furnish work and profit, that a failure of these fruits proves most disastrous to the growers. Every succeeding year does but show how unreliable is hardy fruit culture, for seldom has there been a finer promise than that seen on all kinds of trees a few weeks hence.—A. D.

INDOOR GARDEN.

POINSETTIAS AND THEIR CULTURE.

AMONG plants which bloom from November to January we have nothing more showy or useful than Poinsettias. Their gorgeously coloured heads of the most intense scarlet are attractive above everything during the shortest days, and even a few of them are capable of brightening up stove, conservatory, or rooms in the most pleasing manner when lustrous flowers are scarce and most appreciated. Everyone who has a frame and greenhouse should try to grow some of these, as they are not very extravagant in their requirements and they may be cultivated to a most serviceable degree of perfection with ordinary treatment. Our plants are over by the end of January, and from that time until the beginning of May they remain dormant under the stage of a cool house. They are not watered at this time and have no attention. About the beginning of May they are brought out, watered thoroughly, and then placed in a frame or house where the temperature is about 65°. Here they immediately begin to grow and emit young shoots all up the stems. When these are about 3 inches long they are taken off as cuttings; each one is detached with a heel, i.e., a very little piece of the old wood attached, and they are inserted singly into the smallest sized 2½-inch pots, which are filled with a half-and-half mixture of leaf-soil and sand. They are then plunged up to the rim of the pot in sawdust in a hot-bed or Cucumber house, where the bottom heat is about 70°. Here they are not allowed to suffer for want of water, although they do not require much until the roots are formed, and they are also shaded from bright sunshine. With these attentions roots are soon made, and they are then withdrawn from the bottom heat and placed on a shelf in the pit. In a week or so after this they are shifted into larger sized pots. From 2½-inch pots they are generally put into 3-inch ones, and from the latter into 6-inch or 7-inch ones, and in this size they are allowed to bloom the first year.

IN **POTTING** them we use a rough mixture of turfy loam, sand, and leaf-soil. Proper drainage is of the utmost importance, and firm potting adds to success in culture, and in working with them in this way great care is taken not to injure the roots. They are plants which lose much sap when injured, and this having a weakening tendency must be avoided as much as possible. After potting they are kept close and shaded from the sun for a few days; afterwards they are grown in all the light obtainable. From the last potting on until the middle of September they do remarkably well in a cold frame, and they should never be grown in a strong heat at any time in summer, as this causes them to make long, straggling growths, which are neither ornamental nor useful. Dwarf sturdy shoots always produce the finest heads, and short plants are always more valuable than long

ones. Another way of securing serviceable plants is to cut the old stems down to about a foot from the bottom, and allow all the side shoots which sprout out to grow. In this way some of them may have six, eight, ten, or twelve shoots, and as each of these will produce a showy head, very attractive, or what might be termed specimen plants are the result. When they are treated in this way it is best to repot the old plants, as soon as the young shoots are a few inches long, and they may be potted again when growth is more advanced. As a rule, we bloom these branching plants in 8-inch and 10-inch pots, and apart from allowing the shoots to remain on in the place of taking them as cuttings and the putting them into larger pots, these plants are subject to exactly the same treatment as those raised from cuttings. In the autumn, or about one month before they are required to be in full beauty, they are taken into a warmer and drier atmosphere, and here they soon develop their wondrous heads. Throughout all the period of their growth the greatest attention should be given to watering them at the root, as allowing them to become dry in any way causes the leaves to fall off prematurely, and then the heads are poor and useless.

CAMBRIAN.

NOTES FROM GRASMERE, BYFLEET.

BUDDLEIA GLOBOSA.—Those who may only have seen this flowering shrub in the weakly condition in which it is to be found in gardens generally would, I feel sure, be both surprised and pleased with a large specimen of it now in full bloom in Mr. Joseph Stevens's garden at Byfleet. Although this plant is accounted tender, the specimen in question shows no sign of ever having suffered from climatic vicissitudes, being as robust and healthy as could be desired, each shoot bearing a number of well-developed blooms. Now, as bearing upon this question of hardiness, it is interesting to note that this Buddleia has passed unscathed through two of the most severe winters experienced within the memory of man, whilst others in the neighbourhood have been fatally injured. It is, therefore, evident that under certain conditions it may be relied on to give satisfaction, and these conditions apparently consist of perfect shelter from cold, wintry, and rough winds, of exposure to the sun, and free soil. In the Grasmere garden this Buddleia occupies the south side of a small enclosure, where it is backed up on the north by a wall of Evergreens, and is screened on the east in a like manner. Here it seems quite at home, extending freely and flowering admirably. This flowering shrub is so beautiful and distinct that every effort should be made to induce it to thrive, and, given the conditions above mentioned, I see no reason why it should not be found in a vigorous state in every garden where the soil is of a fairly free description.

PRÆONIES.—These are indeed amongst the most beautiful of hardy spring flowers, the bright hues which many of them exhibit rendering them very striking objects. Amongst the bright-coloured varieties the singles are, I think, most effective, but many of the pale-coloured doubles display much delicacy of colour and considerable beauty of form. Mr. Stevens has them growing amongst standard fruit trees, where they appear quite at home; indeed, these fine flowers are happy almost anywhere.

BULBOUS PLANTS especially worthy of notice are *Scilla campanulata alba* and *Camassia esculenta*. The first-named grows into vigorous tufts, and is as chaste in the individual flowers as it is effective in a mass; it is fine for cutting; the *Camassia* is a noble flower, throwing up its bloom stems from 18 inches to 2 feet high, the large soft purple flowers being loosely set thereon, so as to give it a very graceful appearance. A conspicuous feature in this plant is the long stamens, of the same colour as the flower; they project far beyond it, and are crowned with bright yellow anthers. The vigorous growth of this *Camassia* renders a mass of it very effective.

RHODODENDRON BRILLIANT.—If ever a flower was rightly named, it is this. No variety that I

have hitherto met with can in any way approach it, the flowers being of a most dazzling crimson-scarlet. The effect of a large specimen must be gorgeous; even a moderate sized plant has a most striking and brilliant appearance. Were I limited to one *Rhododendron*, I would certainly choose this one. Another very fine kind is *Leviathan*, not at all a good name by the way, as although the trusses are large, they are most remarkable for the chasteness and delicacy of colour of the individual flowers. Amongst bright flowered kinds, *Braynium* still stands in the foremost rank; it is vigorous and a free flowerer.

AZALEA MOLLI.—Very fine varieties of this useful flowering shrub are now in bloom at Grasmere, and amongst them I would single out *Isabelle Van Houtte*, the flowers of which are very large, of a deep cream colour, the upper petal being strongly marked with yellow, or, more properly speaking, bright maize. It is a singularly attractive and beautiful kind, and should be in every collection. Every garden should possess some plants of *Azalea mollis*, they are so effective when in bloom, and not all fastidious as to soil. Loam or rich peat is often considered indispensable, but Mr. Stevens grows them in his ordinary garden soil, which is very light, approaching sand indeed, and they seem to be doing very well in it. Another very fine kind is *Beali major*, flower salmon-pink, upper petals strongly marked with bright orange—a most telling kind.

ETHIONEMA GRANDIFLORUM.—This is flowering finely on the rockwork, and is one of the most attractive plants there at the present time. One scarcely appreciates this little hardy flower unless the flower-spikes can be counted by the score, and then it really presents a most attractive aspect. It is a charming little plant when in a thriving condition. It evidently prefers a rather light, free soil and good drainage; at any rate, these are the conditions under which it luxuriates with Mr. Stevens.

SOLOMON'S SEAL AND COMMON BRAKE FERN.—I never saw *Solomon's Seal* with a more at-home look than as now growing at Grasmere, in spreading colonies under the shelter of the common *Bracken*. The *Solomon's Seal* is in full flower; the *Bracken* has pushed up around, and amongst it the clear, bright green fronds only just developing and therefore whilst in a measure sheltering do not in any way hide from view the graceful growth and pretty flowers of the *Solomon's Seal*. This is one of the most pleasing combinations I ever saw, the union of these two plants being a most happy one and just what one might imagine would occur naturally. I have seen *Lily of the Valley* and *Bracken* growing together, and this is a pleasing combination, but the *Solomon's Seal* is better, as it is of bolder and more graceful growth. I advise your readers to try this combination in some quiet shady corner where the *Bracken* will not be likely to encroach on other things.

J. C. B.

A NEW FUEL.

DR. HOLLAND, who has for many years been experimenting with mineral oil with the view of obtaining a new fuel equal to coal both as regards the production of heat and light, at length conceived the idea, that if he could not get the heat he wished from oil alone he might utilise the latter in procuring from some other source by its help a heat equivalent, if not better and cheaper than that from coal. Bearing in mind the strong chemical affinity that carbon in a finely divided, or gaseous state, has for oxygen, he foresaw that if he could get steam (which is composed of oxygen and hydrogen) intimately mixed with hydro-carbon gas evolved from the oil, and subjecting the mixture to a high temperature, he would, by taking advantage of the chemical affinity referred to, produce carbonic oxide and hydrogen, two very inflammable gases, and which if burnt in a proper proportion of air would evolve a most intense heat, without any of the smoke, dirt, ashes, or other disagreeables inseparable from a coal fire. This he has succeeded in doing by an apparatus which will before long be shown in this

country. In the fire box of a locomotive or the inside of an ordinary cooking stove, Dr. Holland places, as occasion may require, one or more small iron retorts, each being divided into two compartments. Into one chamber he allows to enter, drop by drop, a steady stream of naphtha or refined petroleum, the flow of which is regulated by a small needle valve. From the top of this chamber a small pipe conveys the gas formed in it to a jet or nipple placed in the middle of the retort about 1 inch below the bottom. From the top of the other chamber, into which water is admitted in a similar way, another pipe takes the steam, when formed, under the retort and terminating in a kind of rose burner of about twenty small pin-holes, completely surrounds the jet used for the oil gas. To start the fire about a teaspoonful of the oil itself is burnt underneath the retort to heat it; as soon as this takes place (in about two minutes) oil is admitted into the retort in minute drops; these falling on the heated surface of the bottom of the retort are instantly converted into gas, which passing out of the jet spreads under the bottom of the retort in a sheet of flame. Water is then in the same manner passed into the other chamber and being converted into superheated steam and passing through the rose burner is intimately mixed with the hydro-carbon gas and atomised against the bottom of the retort, producing perfect combustion and a most intense heat. The actual change that occurs is simply this: The carbon of the gas takes the oxygen from the steam, forming carbonic oxide, and as it is ignited in the atmosphere appropriates another atom of oxygen from the latter, forming carbonic acid. The free hydrogen from both the oil gas and steam combines with a further amount of oxygen abstracted from the air forming watery vapour. The products of combustion being only this watery vapour and carbonic acid, pass away up the chimney without any perceptible dirt or odour. Apart from this the fire once started requires no attention; it can be lit in a few minutes and extinguished in as many seconds. It entirely obviates the danger arising from burning coals and hot ashes falling out into the room. For hot-houses and vineries, where again and again incalculable loss has been sustained by neglect to keep up the requisite temperature, especially during the night, the regularity of the fire (requiring absolutely no attention) coupled with the entire absence of smoke or deleterious gases, will commend the process to all lovers of horticulture. Therefore, now the better seams of coal are rapidly being worked out and the naphtha supply is practically inexhaustible, these facts at least deserve attention.

ENGLISH PLANT NAMES.

"F. W. B." passes summarily over the objections that I should have blocked the way to English names for plants from coming into general use with a remark that it would be better if one's opponents were worthy of good steel. It is evident that "F. W. B." assesses his metaphorical metal at a high standard; nevertheless he is careful not to launch it against an armour of unassailable facts. There is neither ambiguity nor uncertainty about what I advanced on the subject, the very foundation of which was laid by "F. W. B." himself when he (p. 362) says he is not for superseding Latin names, and by which at one swoop he demolishes the ground on which he takes his stand. Well may those who would like to see the Anglicising of plant names become general cry out, "Save us from our friends!" If the cause is to be championed on the lines which "F. W. B." admits. There never was a time so inopportune as the present for initiating such a doctrine of confusion when the trade in plants with the other countries is so much on the increase, a fact which at once points to the still greater necessity for each plant being recognised by a single name. If "F. W. B." and others who take an interest in such matters could devise some means by which the host of plants that are already burdened with a number of names could be relieved from the infliction, they would deserve and receive the unstinted thanks of everyone who is engaged in gardening pursuits, but in place of this they are, no doubt unintentionally, laying the groundwork for a perfect Babel of confusion. The divers opinions put forward by those who advocate the change as to the suitability of any name suggested for any plant that has been spoken of is a forecast of what would inevitably follow. T. B.

PLANTS IN FLOWER.

SINGLE QUILLED DAISIES, a bunch of which has been sent to us by Dr. Stuart, Chirnside, are very pretty, and we do not remember having seen them before. Their flowers are semi-double, and the florets tubular or quilled, varying from white to crimson. Dr. Stuart remarks that it is a very neat plant for rock gardens, and that the flowers make pretty button-hole bouquets.

VERONICA COLENSOI.—Miss Owen has sent us from her garden in Wexford a spray of this rare and beautiful white-flowered *Veronica*, which is now blooming there for the first time. It has proved quite hardy in that part of Ireland during this trying season, and promises to be a valuable addition to shrubby *Veronicas*. The flowers are set on little spikes produced from the axils of the leaves at the end of the branches.

THE SNOWDROP TREE (*Halesia tetraptera*).—Mr. Crook brings from Mr. Sherwin's garden at Farnborough Grange some shoots of this uncommon and pretty tree, each having numerous white bell-shaped flowers dangling in clusters of twos and threes along the whole length of the shoots. Such a pretty hardy tree as this should be oftener planted than it is, for it is not only pretty in bloom, but handsome and symmetrical in growth, provided it is allowed plenty of room to develop, such as on an open lawn. This tree is a native of Carolina, and has been in gardens for nearly 130 years.

ORIENTAL POPPIES.—Messrs. Barr & Son send us blooms of five different varieties of *Papaver orientale*. No. 1 is the typical bracteatum, a distinct variety of *P. orientale*, and remarkable for the large and conspicuous leafy bracts that subtend the flower, which is rich crimson, with a jet black blotch at the base of each petal. No. 2 is like the last in essential characters, but much larger, and is named *bracteatum maximum*. No. 3 has smaller flowers than those of either of the preceding and has no subtending bracts. The colour is a brilliant orange-scarlet and there are no spots at the base of the petals. This very distinct form is named *P. orientale concolor*. No. 4, which we take to be the typical *P. orientale*, is named *orientale maculatum* on account of the black spots on the petals. There is a large form of the last which appears to be a permanently distinct plant. Mr. Barr remarks, "Nos. 1 and 2 differ considerably from Nos. 3 and 4 in the colour of the foliage, which in the two latter is very hairy, more graceful, and altogether distinct from that of Nos. 1 and 2." There are without doubt a few distinct and permanent varieties of the Oriental Poppy besides *bracteatum*, but we think that there are many more names in gardens and nurseries than there are distinct plants to represent them.

RANUNCULUS SPECIOSUS.—Last week Mr. Wolley Dod sent us flowers of the double *R. repens*, and the same plant is in flower in the Hale Farm Nursery, Tottenham, under its other name, *R. speciosus*. This duplication of names is not a little confusing to beginners in hardy plant growing. As we before remarked, it is a showy border flower, having bright yellow blossoms as double and compact as those of a Persian *Ranunculus*, though not quite so large.

NARCISSUS GRACILIS, one of the latest flowering species, is now a conspicuous plant in the Hale Farm Nursery, Tottenham. It has slender leaves and bears flowers nearly as large as those of *N. poeticus*, but clear yellow, with an orange-yellow cup. The flowers are produced on stems three and four together, and are fragrant. It is a fit companion for the double white *N. poeticus* still in blossom in this nursery.

ZEPHYRANTHES TREATLE.—This new *Zephyr* flower is now finely in bloom in the Hale Farm Nursery, Tottenham. It is really a pretty plant, having large white flowers about the size and shape of those of its better known congener, the *Atamasco Lily* (*Z. Atamasco*), but more elegant, the petals recurving beautifully. It is a good addition to the list of hardy bulbous plants, and a

capital plant for a warm sunny border, in company with others of a similar character that require all the warmth one can give them to ripen their growth.

IRIS DICHOTOMA is the name of an extremely handsome Iris now in bloom in Mr. Ware's Nursery, Tottenham. It may be best described as being almost, if not exactly, identical, except in colour, with the commoner *I. pallida*, the species with large lavender-tinted blossoms. The colour of *I. dichotoma* is a beautiful rich purple, a tint seldom found even among the many hued Irises. It is a vigorous plant, a yard or so in height, and bears a plentiful supply of blooms in continuous succession at this season. It is a fine hardy plant for the mixed border or the fringe of a shrubbery.

THE WEIGELAS in Battersea Park are finer this season than we have ever seen them. There seems to be a great variety of tint among them, ranging from deep crimson to snow-white. The white is particularly beautiful; it is very floriferous, the long slender branches forming wreaths of blossoms. Some of the rosy pink varieties, too, are extremely pretty, especially one named *Abel Carrière*, apparently one of the best. In the new part of the park—that skirting the Victoria Road—there are some large vigorous bushes on the slopes where they show themselves off to good advantage.

CORYDALIS NOBILIS.—We have never seen this Fumitory so fine and vigorous as it is this year in the Hale Farm Nursery, Tottenham, where it evidently finds a congenial foothold in the rather stiff soil of that nursery. The stems are considerably over a foot in height, furnished with luxuriant foliage, and terminated by a large, dense cluster of bright yellow blossoms. When seen so rampant as the plants under notice this *Corydalis* is among the handsomest of early summer hardy flowers, and one that would not fail to give satisfaction in any garden. It seems to like a stiff, loamy soil and an open, but sheltered and warm, situation.

GERANIUM ARMENIUM is not only one of the finest of the hardy Geraniums, but also one of the handsomest of hardy flowers, one that should have a place even in the choicest selections. Its flowers are as large as a crown-piece. In colour they are a bright magenta, with a conspicuous jet-black centre, and the petals are also traversed by a network of black veins. The plant is very floriferous, and bears a succession of flowers for several weeks at this season. It is, moreover, a vigorous grower, and small plants of it if planted in good deep loamy soil soon form large circular specimens a yard across and about as much in height. It is a plant not nearly so much known as it deserves to be, considering that it has been introduced for upwards of a dozen years. Some specimens of it come to us from the garden at Grasmere, Byfleet.

CAMPANULA SPECIOSA, a variety of the British *C. glomerata*, is just now one of the showiest of outdoor flowers. It is a plant that should always be included in a choice selection of hardy perennials, for not only is it attractive, but very different from the rest of the Campanulas. Its flowers are of the richest Tyrian purple, produced in large dense heads on stems a foot or so in height. Seen *en masse*, as in Mr. Ware's nursery at Tottenham, it produces a fine effect. It is neat and compact in growth, and does not look so untidy as the more straggly growing Campanulas. It is a tolerably quick grower, particularly in a good loamy soil and an open sunny position, which suits it best.

ROSEMARY-LEAVED SUN ROSE (*Helianthemum rosmarinifolium*).—This pretty little shrub is quite different from the rest of the cultivated Sun Roses. It is of dwarf, prostrate growth, and its foliage, as the specific name implies, bears a strong resemblance to that of the Rosemary. Every twig is crowded with narrow foliage, and this at this season is intermixed with numerous white blossoms as large as a sixpenny-piece. A good-sized plant of it covered with flowers has a pretty effect, particularly if in a prominent position on the rock

garden—its proper place. Mr. Stevens brings from his garden at Byfleet some pretty sprays of it thickly studded with blossom.

AQUILEGIA GLANDULOSA.—A large bunch of this Columbine sent to us by Mrs. Davidson, Ashmore Rectory, Salisbury, shows well what a beautiful hardy flower it is, the contrast of purple and white being very charming. Mrs. Davidson in her note remarks, "The flowers were cut from the same plants which I have had for so long, and I should regret to lose them, for the true *A. glandulosa* is evidently very scarce, at any rate in the south. I cannot depend upon raising young plants, as they seldom come true, I find, even from carefully saved seed."

AQUILEGIA STUARTI.—Under this name Dr. Charles Stuart, Hillside, Chirnside, N.B., sends us a very fine Columbine, which he says he raised from seed some few years ago. It may be best described as a magnified form of the true *A. glandulosa*, of which we presume it is a seedling. It has beautiful flowers of a rich pure blue and with more white on the lower part of the spurred petals than in typical *A. glandulosa*. The oval sepals are unusually large, being nearly 2 inches long by an inch in breadth, and the diameter of the flower is just over $\frac{3}{4}$ inches. The height of the stem is about 10 inches. It is certainly a fine variety, and if vigorous in constitution it will be valuable.

HOYA PAXTONI.—In order to see the full beauty of this charming stove plant, it requires to be seen in the form of a large specimen, such as that which adorns one of Mr. Peacock's stoves at Sudbury House, Hammersmith, where it is a great favourite and grown to perfection. One large specimen in a suspended basket has dozens of clusters of flowers on it hanging gracefully from all sides of the plant. The small white wax-like flowers, in form like a star, with a ruby in its centre, are lovely indeed and their perfume is very pleasant. *H. bella* and *carnosa* are both finely in bloom in the same garden, and both are pretty plants, but not so fine as Paxton's.

TWO GOOD CLEMATISES.—I send a few flowers of Clematis from my alpine house. They are *Lucie Lemoine* (double white) and *Miss Bateman*, both now in grand form, and appear to flourish in all their beauty in spite of a shaded north house. Both plants have increased since last year, although they are in the same pots, such as they were originally packed in. I intend to plant these out in a border in the house, as I am satisfied that one can do these justice even in houses with a minimum amount of sunshine.—W. H. BROWNE, *Aldborough, Hull*. [Two of the best varieties of Clematises for greenhouse cultivation. *Lucie Lemoine* has double white rosette-like flowers. Those of *Miss Bateman* are a delicate blush mauve.]

HARDY PLANTS AT EXHIBITIONS.

TO THE EDITOR OF THE GARDEN.

SIR,—As an occasional exhibitor of these at the metropolitan shows and elsewhere, I may, perhaps, be allowed to make a few remarks about them. Evidently "Delta" has not had much experience as an exhibitor. If he had had to get up a collection of thirty or more distinct varieties of hardy herbaceous plants, he would not have been so severe. According to him, all the London societies are going to the bad. Who would believe, after reading his remarks, that the best specimen *Roses*, flowering and foliage plants, *Ferns*, *Azaleas*, &c., that are to be found in the country, or, at least, that are exhibited at flower shows, were staged at South Kensington? The best *Pansies* from Scotland were there; the fruit and vegetables were magnificent; but "Delta" had no eye for these. He smelt fish, and went home to tell his dolorous tale. The collection of hardy herbaceous plants at the same show was not a good one; that I admit at once, but it is very difficult, even from a very large collection, to get thirty distinct plants all in bloom at one time, at least specimen plants, and nothing less than a good bouncing specimen in a 10-inch or 12-inch

pot will satisfy some judges. They go in for size, and size they will have, or they will send the exhibitor home with a second class award affixed to his productions. I exhibited on one occasion a good collection and gained a first prize with it, but even then I could not get off without some severe remarks about it. It was even stated in an editorial note in *THE GARDEN* that one at least of my plants ought to have been planted in a ditch, where it would have been usefully employed in smothering the Nettles. I took the editor's advice of course and tried it in such a position, but soon found that the plant in question was not adapted for smothering Nettles. I have to say further, if an exhibitor is not to be allowed to force some of his plants to get them in time, it would be better to take the class out of the schedule. Many hardy plants are well adapted for forcing, and can be forced into flower months before their usual time. Many of the *Spiræas* force well, such as *palmata*, and it could not be had in flower at all in the middle of May unless forced. As to *Dielytra spectabilis*, what an excellent plant for forcing it is. Of course, if plants were forced out of character, a good judge would know how to deal with them. Why exclude Lilies from a collection? I exhibited a handsome pot of *Lilium tennifolium* in a collection on one occasion, and it was greatly admired. Then what a lovely plant the common white Lily (*L. longiflorum*) is, but; O, horror! it might want a little forcing. The fact is, if any class of plants are to be successfully exhibited, exhibitors must have as large scope as it is possible to give them. And to those critics who never seem to be happy unless they are fault-finding, I would say for a change try exhibiting, and let us have a practical example of what you can do. That man is a more useful member of society who shows his fellows by practical illustration how a thing ought to be done than one who finds fault with work which he cannot do himself. J. DOUGLAS.

EDINBURGH PUBLIC GARDENS.

WHEN in Edinburgh last autumn we had a few sketches made in the public gardens there, and two of these we now reproduce. These were taken in the Princes Street Gardens from two distinct points of view, and show well the extremes of right and wrong in design. One is from the high ground looking across the valley with noble classical buildings as a background. The effect from this point is admirable, as fine as could be seen in any public park or garden in Europe, and one that our sketch, we regret to say, fails to do justice to. The other view, on the contrary, shows the evil effect of crowding such a noble garden as this is with needless structures, such as shelters, fountains, and bandstands, which tend to mar the beauty and quiet repose that should always be a primary consideration in a garden like this. This sketch was taken from a point in the valley looking along the centre of the gardens. In designing public gardens the position of structures of all kinds, if really necessary, should above all things be well considered; no kind of structure harmonises less with trees and flowers than that of the bandstand and shelter character. For a full account of these and other public gardens of Edinburgh we refer our readers to p. 255 of our last volume.

Saxifraga granulata.—At this time of year very few white flowering plants are more attractive than this, especially if planted in clumps well to the front of mixed borders. It will thrive in any soil; in fact it will grow where other plants, certainly not more beautiful, but more generally cultivated, will hardly exist. Its flowers last a long time when cut, and where white blossoms are in demand they are indispensable, being equally well adapted for table or room decoration, and they may even be used in bouquets if wired. Although this variety of *Saxifraga* is somewhat old-fashioned, it is surprising how seldom one meets with it. It, however, richly deserves more general cultivation.—H. A.

BARTON HALL.

THIS, the seat of Sir C. Bunbury, Bart., lies some two miles north-east from the town of Bury St. Edmunds; it was anciently one of the many lordships of the abbots of St. Edmunds, and after the Dissolution it successively came into the possession of various families, such as those of Kitson, Cotton, &c., and lastly into that of its present owner about the middle of the last century. The park is small compared with others in the neighbourhood, but it contains many fine trees; the principal entrance to it is on the south, or Bury side.

THE MANSION is a large, old-fashioned building, with little architectural pretensions. It contains, however, a very choice collection of pictures of the best masters, many of them being from the pencil of Bunbury, the celebrated caricaturist, who

two sides of the mansion. In the park and contiguous to the east extremity of the flower garden, and distinctly seen from the mansion, are two remarkable Oak trees. They stand some 30 yards apart, and their trunks are nearly 30 feet in circumference; they are supposed to be not less than 1000 years old. They still produce Acorns, and, judging by the decayed Acorn cups upon the Grass under them, appear to be the sessile fruited variety of *Quercus Robur*. They are known as Gog and Magog, and it may well be said of them, they appear so very old,

You'd really find it hard to say
That they could ever have been young,
They look so old and gray.

On the south side of the mansion, and concealed from the flower garden by specimens and clumps

years ago was found to be fully 120 feet, while its smooth stem is as straight as a dart, and it is full 50 feet to the lower tier of branches. This tree is still in vigorous health, and promises in the course of time to considerably increase its present dimensions. Many of the specimens in this collection are memorial trees, or have, as it were, a history attached to them, such as a fine plant of *Æsculus rubicunda* from seed brought from India by the late Col. Bunbury, and planted by him in 1826; *Æsculus flava*, *Æ. pallida*, and *Æ. flore-pleno*, &c.; *Betula pendula*, or Weeping Birch; *Carya amara*, or the Bitter Hickory from North America; *Cercis Siliquastrum*, or Judas Tree; *Acer saccharinum*, or the Sugar Maple from North America, some 50 feet high; *Acer eriocarpum*, a very handsome tree; *Amygdalus communis*, or

General view in the Edinburgh Public Garden.

was a member of the family of the present proprietor of the estate. The principal entrance or front of the mansion faces the north-east, and a portion of this, as well as other portions of the building, is effectively draped with the choicest kinds of hardy climbing plants. A small conservatory abuts upon the south or south-east front, from which extends a very pretty geometrical flower garden, laid down on Grass, with numerous vases of flowering plants, as well as groups of the choicest ornamental shrubs. The roof of

THE CONSERVATORY is well clothed by a fine plant of *Tacsonia exoniensis* and other climbers, while the interior of the house is at all seasons kept gay by a succession of greenhouse plants in bloom, such as the various flowering Begonias, Pelargoniums, Fuchsias, and also by some remarkably fine examples of the old *Campanula pyramidalis*, a very ornamental plant, and possibly now less grown than it deserves to be. Under a temporary shelter may be seen a number of ornamental square pots or boxes, some 18 inches across, each containing a fine strong plant of the *Agapanthus umbellatus*, or blue African Lily; these, with other flowering plants in vases, are arranged with good effect upon the wide expanse of fine gravel which surrounds

of evergreen shrubs and ornamental trees, is a fine lawn tennis ground; and sheltering the flower garden on the north side are many fine and rare species of evergreen shrubs and

ORNAMENTAL TREES. Among others are fine examples of the Lucombe Oak, a very handsome tree, although the timber is considered to be of little value; *Quercus Phellos*, or the Willow-leaved Oak; *Platanus orientalis*, Weeping Birch, Weeping Beech, and Weeping Lime trees, *Catalpa syringæfolia*, *Celtis occidentalis*, *Colutea arborescens*, *Euonymus europæus* (or Spindle tree), Tulip trees, Magnolias, &c. Barton is justly celebrated, as I have said, for its wealth of fine trees and shrubs, and the arboretum, which is some four acres in extent, and lies north-west from the mansion and at a short distance from it, is deservedly considered as the great feature of this fine old place, containing, as it does, many remarkable trees; the soil, being of medium character, neither too heavy nor too light, appears to be well suited to the development of ornamental trees, not the least remarkable of which are some fine examples of the Silver Fir, one of which at 4 feet from the surface of the soil was found to be upwards of 10 feet in circumference, and its height when ascertained some

the Bitter Almond; *Betula fastigiata*; *Cerasus Chamæcerasus*, or the Weeping Cherry; *Fagus asplenifolia*, or the Fern-leaved Beech; *Fraxinus Ornus*; *Gleditsia triacanthos*, or the Three-thorned Acacia; several fine large specimens of *Juglans nigra*, or the Black Walnut Tree, from North America (these are said to fruit freely, but the nuts are of no value); a fine plant of *Liquidambar styraciflua*, and several large and handsome specimens of *Liriodendron Tulipifera*, or the Tulip tree; a fine tall plant of *Salisburia adiantifolia*, or Maiden-hair tree; a fine *Catalpa syringæfolia*, planted in 1826; *Ailantus glandulosus*, or Tree of Heaven; *Virgilia lutea*, &c.—these and many more are all here in the shape of fine specimens.

THE ARBORETUM contains also many fine examples of coniferous trees, such as *Abies Douglasi*, some 90 feet in height; *Abies Morinda* or *Smithiana*; *Abies canadensis*, or Hemlock Spruce; *Araucaria imbricata*, or Chilian Pine; fine Cedars of Lebanon, *Cedrus atlantica*, and *Cedrus Deodara*, *Cupressus Lawsoniana*, *Glyptostrobus heterophylla*, *Libocedrus*, or Incense Cedar; many fine specimens of the Silver Fir, such as *Picea magnifica*, *P. nobilis*, *P. Nordmanniana*, *P. Pinsapo*, &c.; also *Pinus insignis*, *P. monticola*, and various species of *Retinosporas*; *Taxodium*

distichum, 50 feet high; Thujaopsis of sorts; and Wellingtonias of large dimensions; together with many fine evergreen as well as deciduous shrubs, such as Aucubas of large size, the female variety still bearing its scarlet berries; various species of Berberis, Coronilla Emerus, Cotoneasters, Deutzias, Punicas, or the Pomegranate tree; Ribus Cotinus, or the Venetian Sumach; various early flowering and ornamental Ribes, Spiraeas, Weigelas, &c. In this extensive and interesting collection of ornamental trees and shrubs, the very commendable practice is followed of attaching the names of the species to the plants, and in many instances naming the country from which they have been obtained, as well, as in some cases, the date of planting the specimens. This, it will readily be admitted, lends increased interest to the collection. A wall which separates a portion of the arboretum from the kitchen gardens on the east side is very effectively covered with many of the finest species of hardy climbing plants, such as the Ampelopsis, Clematis, Jasmine, Wistaria, Roses, Honeysuckles, and ornamental Ivies, &c., while groups or clumps of sub-tropical plants are effectively disposed at various points upon the greensward, where they harmonise well with the diversified foliage of the various trees and shrubs. The arboretum and grounds present altogether a very large expanse of turf or greensward, all of which is kept under the scythe, Lady Bunbury preferring the cheery sound of scythe whetting to the monotonous humming of even the Silens Messmowing machine.

THE KITCHEN GARDEN is large and in two divisions, and somewhat irregular in outline, and at a short distance from the mansion. The walls are mostly old, but the trees trained to them are healthy and bear well. A Jargonelle Pear tree, which is known to be at least 100 years old, annually produces excellent fruit. The soil being of good quality, culinary vegetables of all kinds are well and abundantly cultivated; while the finest varieties of Apples and Pears are successfully grown in the espalier and pyramidal form, as well as in the form of standards. The principal plant houses are between the mansion and the kitchen gardens in a small enclosure, which is in the form of a flower garden, and the structures, which are nearly new, are substantially built and efficiently heated by hot-water pipes. They are in three divisions; the central one, being a plant stove, contains many fine specimens of large growing tropical plants, and being somewhat lofty affords ample space for their development. Another division is fitted up as a greenhouse and contains a good collection of plants; while the remaining one, which is kept at a higher temperature, contains a collection of stove plants, some choice Orchids and Ferns. The gardens here have long been celebrated for their magnificent specimens of the latter, and they still continue to maintain their reputation in this respect. The stove or central structure contains a few fine Palms, a fine plant of the Pandanus, or Screw Pine, together with Dracenas, Strelitzia, Bougainvilleas, Allamandas, Crotons, and some fine Tree Ferns and fine specimens of Adiantum farleyense, Adiantum gracillimum, &c. In addition to the usual species generally grown in such structures, the plant houses here contain many old and interesting plants, such as are now less frequently to be met with than could be desired. In another part of the gardens is a structure devoted entirely to the culture of exotic Ferns and Selaginellas. It contains artificial rockwork, and the specimens are planted out in pockets formed in the same, or suspended from the roof or walls of the house. The fruit houses are mostly old, consisting of two large vineries, one of which is planted chiefly with the Black Hamburgh variety, and is forced early, and a similar one contains a collection of the later kinds, including Muscat of Alexandria, Alicante, Lady Downes, &c. In all cases the Vines are in excellent health, and give promise of heavy crops of fruit. There are also a small Peach house and houses for forcing Strawberries, Kidney Beans, Tomatoes, &c., as well as for forcing Roses and other plants for the purpose of furnishing at all seasons a supply of cut flowers.

Melons and Cucumbers are grown in abundance, and they are grown in the old-fashioned way, viz., in pits and frames heated by fermenting stable manure.

Mr. William Allan has been the much-respected head gardener here for more than twenty years, and all departments of this fine old place afford ample proof of his good taste, painstaking industry, and skill as a successful cultivator.

P. G.

LEAVES FROM THE SOUTHERN ALPS.

Bowing his head against the steepy mount.

Timon of Athens.

In discussing my botanical finds on Mount Wellington, I shall take the district in its very widest sense, and include certain slopes and low ridges which lie at its foot between the mountain proper and the town of Hobart. This will really include four days' work, two of which were devoted to two ascents of the mountain, and two to investigating the pasture and Gum slopes outside the town. Mount Wellington lies to the west of Hobart, the actual ascent of the mountain commencing about four miles from the town, though these four miles form a very gradual rise which dips somewhat rapidly as you come to the foot. The height of the mountain is 4166 feet—not a great height, but yet I believe the summit offers alpine conditions which would in Switzerland have to be looked for at a higher level. Speaking of New Zealand mountains, the Rev. W. S. Green, in the *Alpine Journal* for November, 1882, expresses the opinion "that the mean snow line in the Southern Alps is 3000 feet lower than in Switzerland, and conditions are met with at 7000 feet which are characteristic of the 10,000 feet line of our Northern Alps." If this is true of New Zealand mountains, we may conclude that Tasmanian mountains also will offer conditions which would be found higher up in the European Alps. Mount Wellington, as seen from Hobart, is a striking and picturesque hill. In glancing along its Gum-clad slopes, the eye finds itself attracted to the very remarkable "organ pipes," a regular arrangement of vertical basaltic pillars, which in the distance look like the pipes of some colossal grand organ. Anyone who has heard the wind howl over the top of the mountains can conceive that sublime music is sometimes discoursed on these pipes when a gust,

By strange conveyance, fills each hollow nook,
As in an organ from one blast of wind,
To many a row of pipes the sound-board breathes.

I myself, when I reached the top, heard some of the "dulcet symphonies and voices sweet" that swept around its antediluvian boulders. Rarely during my stay was the crest to be seen without its turban of cloud. Indeed, this liability to be suddenly wrapt in cloud makes the ascent of the mountain without a guide just a little dangerous. Fatal accidents have occurred, I am told, but not of late; but every summer cases occur of individuals or parties being lost upon the mountain, for if a mist suddenly comes down, the tableland at the top becomes a trackless wilderness of stone, and the only safety for one so overtaken is to find the best shelter he can and wait till the cloud rises. When I proposed one morning to set out alone for the top, a friend of mine, a gentleman of the press, gave me the comforting assurance that if anything happened, I might make sure of an obituary notice. As night drew on and I did not make my appearance, the chances of an accident were earnestly canvassed in the hotel, and my friends were beginning seriously to think of a search party when my appearance at dusk put an end to all anxiety, though my press friend seemed to think me guilty of a fraud to come in this way between him and his opportunities. On the 15th of December, vasculum in hand, I took my place at 9 o'clock in the morning on the box of the Huon coach, which was to carry me four miles nearer the mountain, and so save me time and trouble. The coach is one that runs between Hobart and the Huon River, and I regret not having been able to drive the whole distance along this beautiful route, where magnificent specimens of forest trees are to be seen both of various Gum trees and of the very local Huon Pine (*Dacrydium Franklini*).

Indeed, the few miles between Hobart and the Fern Tree Hotel where I got out is a most delightful drive on a fresh morning; on each side the ground either rises into

EUCALYPTUS SLOPES or dips down into gloomy Eucalyptus hollows, and the banks on either side show patches of colour—yellow, lilac, or white—which are very tantalising when seen from the box of a coach at full speed, but which fortunately I was able to examine closely on the way back. I recognised amongst the plants giving colour to the road-side hundreds of spikes of my old friend, the Trigger plant. The Lilac, which was of a very rich and rosy tint and very abundant, appeared to me to be a *Menziesia*, but when I came to close quarters it turned out to be the pretty *Tetratheca*, probably glandulosa, but as the varieties run so into one another, I shall not be positive; at any rate it is a very lovely flower, just the thing for a commanding niche on the higher part of rockwork. It varies in height from half a foot to 3 feet, and generally forms small, compact, many-branched bushes; both the stems and small serrated leaves are rough with glandular hairs. The long slender racemes are thickly set their whole length with rosy lilac blossoms, which hang face downwards and look like little bells, but which are really cleft into four petals. The herbarium specimen which I collected is just as fresh in colour as when it was gathered; unfortunately, the plants I sent home, of which I secured several with excellent balls, are looking far from thriving, though I shall probably be able to save one. White specimens of *Tetratheca* are sometimes to be found, and they must be very handsome, but I met with none. The *Tetratheca* seems to like sandy heath to grow in, but many of the plants along the Huon grow on hard clay, or on hardy gravelly banks into which it is no easy matter to insert the clasp-knife. I was fortunate enough afterwards to find it in another locality growing in sandy peat, where it was easy to cut out clean adhesive balls. The season, however, though the best for collecting flowering specimens of the various plants, was the very worst in the year for transplanting, especially

HARD-WOODED PLANTS. Along this road, as in many places elsewhere, may be seen numerous plants of a striking white Irid (*Diplarrhena Moraea*). It has narrow, rigid, grassy leaves, and the long stalks, surmounted by several blooms, rise high above them. The flowers are pure white, and when perfect in form resemble a small white Iris, the three inner lobes of the perianth being smaller than the three outer. The texture of the petals is a little flimsy; they seem to last only for a day, and then are very difficult to preserve as herbarium specimens, my specimen showing only the spathe, seed capsules, and an indiscriminate mass of petals. Growing in dry and hard stony places are large numbers of two Leguminose plants, *Dillwynia floribunda* and *Gompholobium latifolium*. The *Dillwynia* has a heathy appearance, the branches being rigid and woody. Sometimes the little orange butterflies of bloom are clustered along the twigs, but sometimes they are found in terminal corymbs. This would be an excellent little shrub to associate with Heaths. The *Gompholobium* is a twiggy decumbent plant, sending out its flexible branches along the ground, or hanging its pleasing yellow flowers over a ledge or down the face of a bank. Besides being pretty, it is a curious and uncommon-looking flower, the inside surface of the petals being of a bright canary yellow, while the outside is a dark olive-green. The dark green linear leaves are arranged in threes plentifully along the stems. This would make an excellent trailer for rockwork, but would probably be a greenhouse subject in England. The plants I sent home, though they had good balls and arrived in good condition, have failed to establish themselves. It probably, however, bears pods abundantly, and can more easily and surely be obtained from seed. In the pastures, where horses and cattle were grazing, the very prostrate branches of *Bossiaea prostrata* with abundance of seed pods crept through the Grass, and also, though not so plentifully, the neat little Coral creeper (*Kennedya prostrata*), an exceedingly attractive trailing sub-

ject even in the flowerless state in which it was when I found it. The leaflets are arranged in threes Trefoil fashion, and the slender branches send rootlets into the ground as they advance through the Grass. When it is covered with its little scarlet Pea blooms, it must be a charming little flower. At the time of my visit the seed-pods were full and plump and nearly ripe. A slight pubescence which covers the leaves and stipules gives a softness to the plant which adds to its beauty. By far the finest of the flowers which I found growing on the slopes at the foot of Mount Wellington was the *Lomatia tinctoria*. This plant also grows in grassy meadows depastured by cattle. I was first attracted to it by the beauty of the leaf, and had secured tidy little specimens about half a foot high before I came upon any in flower. The leaf is exceedingly handsome, being much divided into linear segments like a Fern. The racemes of flower are sometimes a foot long, and often fork into two. The colour is soft creamy white, and the whole truss of flower has a full, rich, curled appearance. When the *Lomatia* finds a secure nook, perhaps on the lee side of a boulder in good rich loam, it makes rampant growth

Heaths in my garden, but, like many another Tasmanian gem, it has refused to take to New Zealand soil. Amongst other plants collected at this part of Mount Wellington I may mention the pretty creamy white *Stackhousia monogyna*, of which I found only a single flowering specimen, though it is common enough throughout the island. The two Tasmanian Violets, *Viola hederacea*, a very widely spread little herb, covering the knolls and banks with its simple flowers of a quiet inconspicuous kind of beauty, the colour a greyish white flushed with lilac, and *Viola betonicaefolia*, which was not then in flower, but which Hooker says resembles its English congeners, *Leucopogon virgatus* with little Chickweed florets, and the curious but graceful *Drosera peltata*, growing in little colonies through the Grass. On a shady bank amongst the herbage, in a loose gravelly soil, grew the little ground Orchid, *Chiloglottis Gunni*, a quaint little species with a trowel-shaped labellum.

PAKEHA.

POPULAR WEATHER PROGNOSTICS.

In the quarterly journal of the Meteorological Society for last January, which, however, is only

right (in the northern hemisphere)." The wind always blows in a direction nearly parallel with the isobars or lines of equal barometric pressure. Two diagrams are given, showing a cyclone with its well-marked features and the weather in various parts of its area. In the front of this cyclone or depression, or area in which the barometer is low, "there is a blue sky; then, as the barometer begins to fall, and sometimes even before that takes place, a bank of cirro-stratus, preceded by a halo-bearing sky, makes its appearance, which gradually becomes lower and denser, and forms an overcast, dirty sky. In the whole front of the depression the temperature rises, and the atmosphere feels muggy and close. In the right hand front the clouds assume the cumulo-stratus type, with driving rain later on; in the left hand front the air is cooler, but still oppressive, with an easterly wind and overcast sky, succeeded by drizzling rain or ill-defined showers. When the trough of the depression has passed, the barometer begins to rise; the wind changes and becomes squally, with showers of rain; the air grows cooler and the clouds break and ultimately clear away." Now, how do the popular theories about the weather agree with these views?

HALOS AND MOCK SUNS are signs of rain. "When round the moon there is a brugh (halo), The weather will be cold and rough." Out of 155 solar halos only twenty-six were not followed by rain within three days, or 83 per cent. were followed by rain within two days, and out of sixty-one lunar halos, 49 or 80 per cent. were followed by rain in three days. A watery sun is also considered a sign of rain. "If the sun goes pale to bed, To-morrow will be wet," 'tis said." This pale or watery appearance is caused by the thin clouds which are the precursors of the heavier ones. At this period the amount of moisture in the air, even though the sky may be tolerably clear, causes clouds to form round the tops of hills, the man to come out of the old-fashioned weather houses, a piece of dried seaweed to become flabby, the flames of oil lamps and candles to snap and burn unsteadily. As the depression approaches and the atmosphere becomes gloomy, close, and muggy, some people are troubled with rheumatic pains and neuralgia; old wounds and corns are painful. "A coming storm your shooting corns pre- sage, And aches will throb your hollow tooth with rage." Drains and ditches give out an offensive smell; animals and birds are restless, and seem to feel the impending change. "Hark! I hear the asses bray; We shall have some rain to-day." Again, "When the peacock loudly bawls, Soon we'll have both rain and squalls." Birds flying low, and rooks falling about like tumbler pigeons are sure signs of rain. Goats and flies bite sharply before rain. As the centre of the depression approaches still nearer rain sets in, and continues till the barometer turns to rise. As the centre of the depression passes, there is often a heavy shower or squall, usually spoken of as "a clearing shower; immediately the air becomes cooler, small patches of blue sky appear, the steady rain changes into showers, and the sky again becomes clear. How often after heavy rain do persons look for the first break in the clouds, and wonder if the first blue sky that they see is large enough to make a pair of Dutchman's breeches. The truth of the old rhythm, "When the wind veers against the sun, Trust it not, for back 'twill run," is shown by the fact that the wind on the right hand side of the depression at its approach backs to south, falling very light, and then gradually veers to S.W. and W. with increasing strength. We have now seen how many of our popular signs of the approach of bad weather may be depended on. Before passing to those indicating

FINE WEATHER there are some that should be considered which foretell bad weather, and yet are not amongst those influenced by a cyclone. There are often periods when neither the centre of a depression nor of an anti-cyclone has passed immediately over us during which the lines of equal barometric pressure do not form an oval or circle, but are wedge-shaped or angular, and fit in, as it were, between the oval lines forming a past and approaching depression. During these periods the

Sketch in Princes Street Gardens, Edinburgh, showing the bad effect of needless structures in the central part (see p. 510).

several feet in height, and the flower trusses are correspondingly rich. In more exposed places it is dwarfer and less floriferous. It seems to send out subterranean runners, which will account for its gregarious habits, for it is patchy in its habits. This *Lomatia* would have been a really valuable addition to our border plants of the shrubby kind, but my specimens, well balled though they were, have refused to survive their transportation. The last plant on the lower slopes of Mount Wellington that I shall notice at length is the woody little shrub *Hibbertia stricta*. A remarkable fact about the genus *Hibbertia* is that, whereas nearly one hundred species are known from Australia and Tasmania, the genus is strictly confined to these two islands. It is a wonderful fact in the distribution of plants that New Zealand, for instance, should have no representative of this family so abundantly represented in the neighbouring continent. Hooker remarks that, "though there are nine species in the colony (Tasmania), none are alpine and few ascend to the sub-alpine zone." Of the nine species, I collected four, but only *stricta* on Mount Wellington. Of the other species I may have something to say if I touch on the botany of Brown's River, to which I devoted a day. *Hibbertia stricta* has the shrubby, almost beathy appearance of a *Diosma*, and is thickly studded with five-petalled bright yellow flowers, which, as Hooker says, "recall the *Cisti* and *Potentillæ* of Europe." I found it growing plentifully on a steep hill-side near Hobart, facing the north—a very sunny exposure, the soil a sandy peat. I was so taken with the brightness of the blossom and the neatness of the little shrub (if so small a thing can be called a shrub), that I carefully dug and packed a number of plants, thinking it would be an excellent subject to associate with hardy

just published, there is a very interesting paper by the Hon. R. Abercromby and Mr. William Marriot on popular weather prognostics, in which they show how true many common sayings about the weather are. The very prevalent ideas about the influences the moon has on the weather are, curiously enough, not even alluded to; they, however, hardly come within the scope of this paper, as they cannot be proved by any scientific observations. It is frequently said that as the moon so largely influences the tides, it must therefore have some influence on the air and clouds, and so cause a change in the weather; but the propounders of this theory forget that the moon influences the tides daily, indeed continually, and not four times a month only, and that to make the cases parallel the weather should change four times a day, which, however fickle this climate may be, is very seldom the case. It is very satisfactory to learn that so many of our popular prognostics have been proved to be correct by the most scientific deductions. The paper commences with a lucid description of the manner in which a

CYCLONE or anti-cyclone influences our weather, and shows that there is nearly always present either an area of low barometric pressure called a cyclone, usually having a nearly circular form, and as a rule moving in an easterly or north-easterly direction, or an area of high pressure called an anti-cyclone, also nearly circular in form, but almost stationary in position. In cyclones this wind circulates in the opposite way to which the hands of a watch move, while in anti-cyclones the wind circulates the same way as the hands of a watch, and the law is quoted which was first propounded by Dr. Buys Ballot, that if you "stand with your back to the wind the barometer will be lower on your left hand than on your

weather is usually beautifully fine, though it does not last long; on these days we say, "it is too fine to last," and at night there are white frosts, which seldom occur more than three nights in succession, while during the day the sun is particularly burning; distant objects and the landscape generally are unusually distinct. "The further the sight, the nearer the rain." The reason of visibility is uncertain; the old and common notion that it was due to excess of vapour is certainly erroneous; the dry and wet bulb hygrometer always indicates a considerable amount of dryness, when it is remarked, and Mr. Cruickshank has shown by long observation at Aberdeen, that visibility is greatest at the driest season of the year. Great audibility was, and is often now, attributed to dampness with just as little truth. As regards anti-cyclones, the lines of equal barometric pressure surround large areas, and are some distance apart. "The pressure is highest in the centre, and gradually diminishes outwards. The air is calm and cold in the central area, but on the outskirts the wind blows in the direction of the hands of a watch. These are the special features of an anti-cyclone." The weather is just the opposite of that in a depression, being usually settled and fine. Anti-cyclones are nearly stationary instead of moving rapidly, as depressions do. As under these circumstances the sky is "generally clear and the air calm, the temperature is high during the day and low at night. In summer brilliant sunshine prevails during the day, and at night there is a heavy dew, and in low-lying places mist. In winter frost is generally prevalent in the central area of an anti-cyclone, accompanied frequently by fog." Most of the signs popularly supposed to indicate fine weather may, therefore, be relied on, such as a heavy dew after a hot day; a mist rising on low ground, gradually ascending and vanishing in the morning. "When the mist creeps up the hill, Fisher out and try your skill." Birds flying high (except swifts); sea birds flying out far and early to seaward.

WHITE MIST in the evening indicates frost; also vapour rising from a river; fires burning rapidly with a blue flame (this is caused by the reduced temperature of the outer air making a better draught in the chimney). "Clear moon, Frost soon." As the anti-cyclone is nearly stationary, the wind blows from the same quarter for several days together. "If the wind is north-east three days without rain, Eight days will pass before south wind again." Sometimes in winter on the southern side of the anti-cyclone bitter east winds with a black-looking sky will prevail, when it may truly be said, "When the wind is in the east, 'Tis neither good for man nor beast." In conclusion, the authors say they are unable now to enter "into the complicated question of the non-cyclonic rain-falls in this country. It will be enough to state that the prognostics which precede them are rather those associated with broken weather, such as bright sunrises or heavy clouds banking up without the barometer falling, than the muggy, dirty weather of a cyclone front. The warning they give is also much shorter—rarely more than three or four hours, if so long. It is much to be wished that persons would study more carefully than they generally do at present the various signs that indicate a change in the weather, as the knowledge they would thus acquire would be very useful, particularly to those engaged in horticulture. Unfortunately at present, the weather knowledge of most persons is well described in the following old Bedfordshire lines:—

Well, Duncombe, how will be the weather?
Sir, It looks cloudy altogether.
And coming across our Houghton Green,
I stopped and talked with old Frank Beane.
While we stood there, sir, old Jan Swain
Went by, and said he knew'd 't would rain.
The next that comes was Master Hunt,
And he declared he knew'd it wouldn't.
And then I met with Farmer Blow;
He plainly said he didn't know.
So, sir, when doctors disagree,
Who's to decide it, you or me?

G. S. S.

BOOKS.

BOOKS ON ALPINE FLOWERS *

THE works on alpine flowers are numerous, but the subject has not yet been exhausted, nor even adequately treated, though the German authors are far in advance of the English. We do not speak of the learned botanical works that are only to be found in scientific libraries, but of books intended for the lover of flowers more or less ignorant of botany. The little work in four pocket volumes by J. C. Weber is still, perhaps, the most popular of the illustrated books, but it gives very little information besides the pictures and the names of the 400 selected species, which are, however, well chosen.

The illustrations are more carefully drawn and coloured in the work called "Die Alpenpflanzen," of Seboth, in four volumes, published by Tempsky at Prague. Two volumes have been re-edited, and the text translated by A. W. Bennett. The four volumes are, however, too bulky for the traveller, and very inconvenient as a book of reference. Having been published in numbers, the different species of each tribe are scattered, and one is forced to hunt through four volumes on the chance of finding the particular Anemone, Gentian, or other flower that may be wanted.

There is another work in course of publication at Vienna entitled "Atlas der Alpenpflanzen," with text by Dr. K. Dalla Torre. The illustrations are so far most carefully drawn and coloured, but as no text has yet appeared it is impossible to judge of the plan of the book as a whole. No colour printing can, however, do justice to the delicate beauty and brilliancy of alpine flowers.

There is a large folio volume recently published by Sampson, Low & Co., entitled "Wild Flowers in Switzerland, or a Year amongst the Flowers of the Alps," by "H. C. W." It is a very ambitious work, professing to be written for the traveller unlearned in botany, but no book is of any use that is not available on the spot, and the size alone of this book renders it an impossible encumbrance for the bag or the knapsack of the mountaineer. Nor can the book have any attraction for a true lover of art, on account of the coarse drawing and the bad colouring of the flowers. The universal smoke-coloured backgrounds are a great mistake. All delicate flowers come out best on white paper, and even white ones need only a pale tint of fawn or grey to show them up. The grouping and selection of the plants are even more in fault.

The book contains sixteen plates, each plate showing on an average twelve plants. The plants are so crowded and confused as to be quite unintelligible to the ordinary observer, while to anyone well acquainted with them, the crowd of the various flowers, leaves, and stalks into one plate is even more perplexing and irritating than the plates in that otherwise charming work by Anne Pratt in five octavo volumes, called "Flowering Plants of Great Britain," where a similar plan of grouping several flowers on one page has also been unfortunately adopted. "H. C. W." professes to have grouped the flowers as to time of blooming and place of growth, but every plate has many errors in both these respects. Flowers of the high Alps and rocks are mixed with those of the sub-alpine meadows, and roadside weedy plants are also introduced. In some plates flowers and their seeds or berries are represented together; in some cases flowers are found in one plate, seeds in another, and in some instances seeds or berries only and no flower; altogether there is a want of

Wild Flowers in Switzerland, or a Year amongst the Flowers of the Alps. By "H. C. W." London: Sampson, Low & Co. 1883.

system throughout, as well as an absence of taste in the selection.

Each of the coloured plates is accompanied by an outline index plate; the reference numbers are occasionally incorrect, but the outline drawings are often more characteristic of the plants than the coloured plates! Many of these remind one of the too common fault in making bouquets and arranging flower vases where the object seems to be to crowd in as many different kinds and colours of flowers as possible, instead of showing each kind separately in its beautiful natural growth, with its own garnish of leaves, or if these do not accompany it in Nature, adding only a few simple Grasses, or Ferns, or Evergreens, such as might be found growing near in its wild state.

There may be some difficulty in deciding precisely what is an alpine flower, but the abundant variety of Ranunculus, Anemone, Dianthus, Vetch, Potentilla, Saxifrage, Campanula, Gentian, Primula, Androsace, Orchids, and bulbs, without mentioning the rarer Grasses, Ferns, shrubs, and climbing plants, would suffice for many books before we need descend to the common Houseleek, the blue Sow Thistle, the yellow Goat's-beard, the Marsh Red-rattle, the common Bistort, the carline Thistle, the common Elder, and the common Dodder. The author has taken great pains with the names of the plants; the Greek or Latin derivations of the scientific names are explained, and their synonyms are added in English, French, and German.

It is with regret that we are forced to protest against the bad art of a laudable attempt to popularise the beauties of the alpine flora, but "art is long," far longer than any amateur who rashly enters upon its path can believe. H.

OBSERVATIONS ON INJURIOUS INSECTS IN 1882.*

THIS report, which is annually compiled by Miss E. A. Ormerod, has just been published. It contains the observations made by various persons interested in horticulture and agriculture on the insects which have affected their crops during the past year. This report quite comes up to those of former years in general usefulness and in the value of the practical suggestions which it contains. Last year's report specially dealt with the attacks of the Turnip flea beetle, which had been particularly injurious in many parts of the United Kingdom in 1881. This year prominence is given to a no less destructive insect, the wireworm, but the year 1882 does not appear to be noted for any unusual demonstrations by this insect; nor, indeed, does it appear to have been remarkable for the abundance of insect pests, nor for the virulence of any special attack, with the exception of the Hop aphid, which in many places destroyed the entire crop. Yet in looking over the figures supplied by many observers of the amount of loss they estimated insects had caused to their crops, one cannot but feel that, if we could in any way secure immunity to our crops from these pests, market gardeners and farmers would be in a very different position from what they are now. Crops that at present hardly pay, or are perhaps a loss, would then yield a handsome profit; many times when it is said that it would not pay to do such and such things to destroy insects, if those means were used and the insects destroyed, the extra yield from the crops in consequence would amply repay the trouble and expenditure. Miss Ormerod, though fully recognising

THE UTILITY OF BIRDS, and the great assistance we receive from them in destroying insects, says: "It is a matter for serious consideration whether the great encouragement of bird life beyond the natural balance, such as is now often recommended, may not lead to very contrary results to what is intended. Besides the damage that over numbers of birds may cause to young crops or ripe Corn, it ought also to be borne in mind that many insects (such as carnivorous beetles and

* "Report of Observations on Injurious Insects during the year 1882, and Special Report on Wireworms." By Eleanor A. Ormerod. Simpkin, Marshall, & Co. 1883.

their grubs, and the grubs of ichneumon flies) live wholly or in part by feeding on their fellow insects; and it is desirable to consider how an unnatural surplus of birds bears on the matter of diminishing these helpers. Without in any way doubting the necessity of the presence of a proper amount of birds, I think it would be well worth while, by examination of the contents of the stomachs of some of the smaller birds, to gain clearer views of what is the chief part of their insect diet." This is all very well, but how are we to ascertain the natural balance? Were the entire country uncultivated and the wood unpreserved, no doubt the natural enemies of the birds would be far more numerous than they are now, and the birds in consequence less; also the birds which feed on insects would have no such opportunities as they now have for obtaining their food, for under these conditions there would be enormous swarms of insects as there are at times now, such as the Gamma moth, Turnip sawfly, and many others, as there would not have been sufficient quantities of their food plants to support so great a number. But the balance of Nature has been so tampered with, and it now oscillates so continuously, that it seems impossible to restore its equilibrium. By cultivating our land and causing a great preponderance of certain kinds of plants, the insects which feed on these plants naturally increase; at the same time the natural enemies of our birds are much diminished in numbers. Still, it seems clear that the insects increase with greater rapidity than the birds, and that if we wish to save our crops from the former, we must not destroy the latter; it is far easier to keep birds from a crop when it is certain it will be injured by them than to attract or encourage birds when their numbers are few and their presence desirable. What is "the proper amount of birds?" is a very open question, but it perhaps may best be answered at present (as far as most kinds are concerned) by saying as many as possible. Any carefully made investigations, however, on this subject will be very valuable.

INSECTS REPORTED ON.—This year ten insects are reported on which have not hitherto been mentioned in any of the reports, namely, the winter moth (*Cheimatobia brumata*), so called from its appearance in November and December, whose caterpillars are very destructive to the leaves of various fruit and other trees. They appear to have done serious mischief in many places. The females have very small wings, and are unable to fly, so that as the chrysalides are formed in the ground, anything of a sticky nature, such as a band of newly tarred canvas placed round the stems of the trees will prevent the moths ascending them to lay their eggs. The Ash-bark beetle (*Hylesinus fraxini*) which forms galleries under the bark of Ash trees. The Asparagus beetle (*Crioceris asparagi*), which may often be found on the Asparagus; its grubs feed on the foliage and consequently weaken the plants. After syringing the plants with water, a shake will cause the grubs to fall, then a sprinkling of quicklime or soot will kill them. The Cherry aphid (*Myzus cerasi*), a black blight which sometimes covers the leaves and young shoots of Cherry trees. The great difficulty in destroying this and many other kinds of aphid is that the insects make the leaves curl so that it is very difficult to cause any insecticide to reach them. The Clover root weevil, the grubs of which gnaw the roots, and the weevils destroy the foliage. The Wheat bulb fly (*Hylemia coarctata*), whose maggots feed inside the stems of the young plants. The Hop aphid (*Phorodon humilis*), whose destructive capabilities are only too well known to Hop growers. The Hop flea beetle (*Psylliodes attenuatus*), an insect much resembling the Turnip flea beetle only of a brassy green colour. The Mustard beetle, which devastates fields of Mustard and Rape, and the Spruce cone gall midge (*Cecidomyia abutilis*), which infests the cones of the Spruce Fir, without, however, doing much injury. Among the insects which were particularly injurious in gardens last year was the Apple-blossom weevil (*Anthonomus pomorum*). The weevils fall when alarmed, and the females seldom fly, so that by placing a tarred

band round the stems of the trees and then smartly jarring the branches, they will fall, and be unable to return. The Carrot fly (*Psila rosæ*) was very injurious in some places. In reference to the damage often caused to Turnips, Cabbages, Carrots, and Parsnips by the wireworm, it is said that sowing the seed with a liberal dressing of farmyard manure, and dressing with 2 cwt. best bone meal, 1 cwt. nitrate of soda, and 3 cwt. of common salt, soon forces the plants beyond the reach of injury by them. As regards the Onion fly, our contributor says that two years' trial of the effect of earthing up Onions has made me think the plan would save much loss wherever the Onions are sown in drills, so as to admit of earthing by the hoe. The Pea weevil (*Sitona lineata*) does much damage to the leaves of young Pea plants, and is well known, but hitherto the habits of the grubs were a mystery; it is, however, mentioned in this report that the grubs have been found feeding on the roots of the Peas and on the little wart-like excrescences so often found on the roots. In previous reports a very good figure has been given of this insect, but in the present one a very inferior figure has been substituted, which is a pity.

THIS REPORT is printed, like its predecessors, very clearly, and a good index renders reference to it very easy. Miss Ormerod and the various contributors who have enabled her thus to record the result of their experiments deserve the best thanks of all interested in horticulture. S.

AMERICAN NOTES.

The true *Deutzia scabra*.—Some plants of the true *Deutzia scabra*, grown in pots in a cool greenhouse at the Arnold Arboretum, are now in blossom. The flowers are white, pretty and copiously produced, and the habit of the shrub is good. It is a hardy shrub and one of the rarest in cultivation. True, we often find its name quoted in catalogues, but *crenata* is the kind that is usually sold for it. I am not aware that it is in commerce.

Potato crops.—Last year we raised at the rate of over 700 bushels of Potatoes with one variety; over 600 with several; over 500 with many. Some of our good friends doubted it, though our estimates were thoroughly fair and accurate. This year we hope to do better, and at harvesting time we think we shall secure the services of several surveyors to measure the land and yield and several justices of the peace to take our affidavits thereto.

The Russian Mulberry.—I do not know where seed of the Russian Mulberry can be secured in quantity, except by importing it direct from Russia. From seed it runs into many variations in form of tree, character of leaf, and size, quality, and colour of the fruit. For silk-worms or fruit it will be best to grow it from cuttings. From our experimental grounds we have sent out several hundred plants this spring grown from cuttings. Nearly every cutting made a bushy plant from 2 feet to 3 feet in height. I cannot believe it will prove valuable as a timber tree east or west. Last summer I attended a forestry convention held on the grounds of the Agricultural College near Moscow, Russia. Several hundred forestry managers were present from all parts of the great empire. Every person to whom the subject was broached laughed at the idea of the *Morus tatarica* being valuable for timber in competition with their Oak, Birch, Elm, Basswood, White Poplar, or Riga Pine. As I saw it in Southern Russia, it is a low bushy tree, noted specially for persisting in throwing out limbs from the crown upward like the *Morus multicaulis*. Yet it will prove valuable on the great prairies of the west as an ornamental tree, and for use in shelter belts where its fruit will have value as food for the birds and to some extent for household use.—PROF. J. L. BUDD, *Iowa*, in *Rural New Yorker*.

A large Vine.—Captain W. G. Phelps has a Grape Vine that is now believed to be the largest

in the United States. In 1867 the large Vine that was famous in Southern California was cut down and exhibited at the Centennial Exposition. It measured 14 inches in diameter. This Vine of Captain Phelps is twenty-five years old and is 13 inches in diameter. It is of the Mission variety, and it has never received the benefits of irrigation. It stands near the house, south of Stockton about two miles, and it covers about 4000 square feet of ground. If it had been permitted to run where it wished it would have covered a much larger area, but it was found necessary to cut it back in order to save the roof of the house. The largest crop that grew was two or three years ago, when, after selling a ton and a half by actual weight, the remainder was estimated at two tons and a half.—*Pacific Rural Press*.

Early Potatoes.—A correspondent of the *Country Gentleman* says: "The earliest Potato is the Early Electric. Last season, in order to test the comparative earliness and yield of the new varieties alongside the well-known kinds, I planted at measured distances a definite number of hills of each of the kinds given in the following table. They were all planted in the midst of a field of Potatoes, and given the same cultivation as the whole field. Single eyes were planted, one in a hill, on the 15th day of May:—

Name.	Time of ripening.	Product per acre.
Early Electric ..	Aug. 7 ..	934
Early Ohio ..	Aug. 15 ..	1164
Early Mayflower ..	Aug. 15 ..	1774
Brownell's Best ..	Sept. 7 ..	2374
Clark's No. 1 ..	Sept. 1 ..	1624
Early Telephone ..	Aug. 15 ..	175
Beauty of Hebron ..	Sept. 1 ..	1794
Early Rose ..	Sept. 1 ..	169
Magnum Bonum ..	Sept. 10 ..	1574
Late Rose ..	Sept. 15 ..	194
Snowflake ..	Sept. 7 ..	189
White Star ..	Sept. 25 ..	206
White Elephant ..	Sept. 25 ..	232
Burbank ..	Sept. 25 ..	220
Matchless ..	Sept. 15 ..	135
Pride of America ..	Sept. 25 ..	1914
Late Snowflake ..	Sept. 25 ..	2264
Belle ..	Sept. 15 ..	225
Defiance ..	Oct. 1 ..	3324
St. Patrick ..	Oct. 1 ..	250
Rose's Seedling ..	Oct. 1 ..	223
Roger's No. 4 ..	Oct. 1 ..	1994
Watt's Orange ..	Oct. 1 ..	2374
Queen of the Valley ..	Oct. 1 ..	199
Champion of America ..	Sept. 25 ..	258
Roger's No. 7 ..	Sept. 25 ..	258
Cook's Superb ..	Sept. 25 ..	2544
Silverskin ..	Sept. 25 ..	234
Mammoth Pearl ..	Sept. 25 ..	257

The dying of the tops was taken as the period of ripening. It will be seen that the Early Electric is three weeks earlier than Early Rose. Had it been planted very early, I presume the yield would have been satisfactory. The Defiance was by far the best producer and good in quality. The handsomest Potato was Rose's Seedling, all of which were large."

Asparagus beds.—The old and costly way of making Asparagus beds by deep trenching is properly objected to in most cases. Mr. Harris says the first bed he ever planted must have cost in labour and manure at the rate of £200 an acre, with no better results than are now obtained with one-tenth of the expense. He now makes the rows 4 feet apart, with the plants 2½ feet apart in the row, for horse cultivation both ways. Plants thus treated throw up large shoots earlier in the season than plants in a thick bed, and give heavier returns.—*Country Gentleman*.

Inland parcels post.—A Post Office circular addressed to merchants, traders, farmers, seedsmen, florists, and the public generally states that, the inland parcels post being appointed to commence on the 1st of August next, the Postmaster-General desires to call attention to the circumstance that the arrangements for bringing it into operation will be greatly facilitated, and the risk of delay in the transmission of parcels largely obviated, if senders of parcels in large quantities (whether it be the intention to post the parcels daily or at regular or irregular intervals) will so far as possible notify their intentions to the nearest postmaster or sub-postmaster as early as convenient in the present month. It is not essen-

tial that the number and weight of the parcels and the frequency of posting should be specified with absolute decision; it will be sufficient if a general idea can be given, so that some provision over and above the ordinary means available may be arranged for in advance of the date fixed for the commencement of the post. Parcels not exceeding 1 lb. will be charged 3s.; exceeding 1 lb. and not exceeding 3 lbs. 6d.; exceeding 3 lbs. and not exceeding 5 lbs. 9d.; exceeding 5 lbs. and not exceeding 7 lbs. 1s.

UTILISING COUCH GRASS.

I HAVE clipped from the *Clonmel Chronicle* the following extract relating to this matter—one of great importance to farmers and gardeners:—

"At the Horse Show in Dublin last year I mentioned to an enterprising Scotch farmer, now in Kildare, who complained of being plagued with Couch Grass, the method I adopted of not only completely killing it, but of utilising the residue as manure. He laughed at the idea of turning to use what had hitherto been to him a curse as well as a source of serious expense. He never heard of any method of extirpating it that fully succeeded but burning, and except that is thoroughly done—a partial smouldering will not do—the joints escape and grow luxuriantly wherever the ashes are scattered. I prevailed on him to try my plan of killing it by smothering or suffocation, and recommended lime or sifted coal-ash for the purpose. Within the last few days I had a letter from him to say, 'the lime plan had completely succeeded,' and that he was then using for top dressing some paddock land that had been used for sheep and young stock in the winter 1000 loads of as fine a compost as he ever saw. Last year I found that when the green crops were sown, we had at least 400 loads of Squitch or Couch Grass, Crowfoot, and other bad weeds that die hard, and that give the cultivator immense trouble. If these were burned our heap of 400 loads would diminish to a twentieth part, and all the vegetable or organic part would be gone, and though the ashes would be useful in many ways, the most valuable constituents would be lost. I adopted the suffocating or smothering process already referred to. The weeds and all noxious rubbish were ranged in an oblong heap, and this was covered with ten loads of lime, fresh from the kiln. It soon slaked, and the slaking produced heat; but it is not on the heat thus evolved, as many suppose, that I relied to suffocate or kill the Squitch. It was on the air-tight mass, 6 inches thick, on the top of the heap I had confidence, and I was not disappointed. This mass of lime on the surface became thoroughly impermeable to air, and, as a matter of fact, all vegetable life underneath was effectively killed. Before six months had elapsed I was using the compost thus produced for mixing with straw and other material, and for absorbing the liquid around the manure heap. Except where the lime did not reach on the sides, not a particle of life is now in 1 inch of the afore-mentioned mass of Squitch. Some hundred loads or more still remain, and this is every alternate load mixed with farmyard manure, and makes an excellent dressing for any green crop, and for this purpose it is now utilised. Clay being permeable to air, is valueless for this purpose, and this is why so many fail to kill Squitch Grass in heaps.—W. J. MURPHY."

I may add that I have long since given up the practice of burning the weeds of the garden with the various prunings, &c., which are burned by themselves. The weeds of all kinds, including Dock, are put into a heap as they are taken up, and when the manure comes from the stables plentifully in winter I mix the heap of weeds layer about with it, keeping the weeds at least 6 inches from the outer edge of the heap all round. This prevents violent heating, but is quite sufficient to destroy all life in the roots; in fact, they become a mass of pulp, strongly impregnated with the ammonia of the manure; besides the latter is not merely so much wasted as if put to rot by itself. Thus I have a great mass of the richest manure, very much enhanced in quantity compared with

what I used to have before utilising the weeds—three loads at least in place of one. I have a very large garden to find manure for—10½ acres—from a limited source, and by using up all the weeds of the season in this way, I am almost independent of artificial manure, for which I must say I never cared very much. I had once a quantity of Couch Grass collected by the harrows from a very dirty field, thrown into a deep gripe impervious to air everywhere but at top; some green rubbish was thrown over it, and it was forgotten till the summer of the second year. When I chanced to examine the heap I was so astonished at what I met with, that I used it largely in the culture of Pines, and with the best results.

Kylemore Castle, Galway. JAS. GARNIER.

GARDEN FLORA.

PLATE CCCXCI.

MARIE BAUMANN ROSE.

IT is just twenty years since M. Baumann was so fortunate as to raise this truly magnificent Rose. The year 1863, though less rich in novelties of sterling merit than some of the years that preceded and succeeded it, yet gave us, among others, such fine permanent varieties as *Pierre Notting*, *Lord Macaulay*, *La Duchesse de Morny*, *Centifolia rosea*, and *Madame Victor Verdier*. Beautiful and indispensable as are these Roses to the rosarian, few will place either of them on the same plane of merit as *Marie Baumann*. The annexed plate paints its vivid colour, and delineates its all but matchless form far more accurately as well as eloquently than any pen and ink sketch can hope to do. And yet in the presence of this and other lovely Roses, as in that of perfect pictures, we become spellbound with a semi-mania for description. To keep silent seems almost an insult to the art and genius that brings us so much pleasure; and hence the pen rushes to the aid of the pencil and the brush to render art or Nature more intelligible or attractive 'o a larger circle of readers or observers. But to attempt to describe a Rose so faithfully put on the pages of *THE GARDEN* may seem to many a work of as useless supererogation as to re-sculpture the alabaster cup of the fair Water Lily that crowns the depth of silvern pool "with fearless grace—a stately river queen." The fine form, substance, and colour of *Marie Baumann* are all that can be desired. A change for the better has come over rosarians in regard to size, which has no longer the place and power in their estimation that it once held. Mere grossness is now more likely to lose than win prizes. Still, other conditions, such as form, quality, colour, fragrance, being equal, the more of them, that is the larger the Rose in reason, the better, and *Marie Baumann* is only reasonably, not monstrously large, and the illustration shows it to be of full size. Being, however, as far as possible removed from coarseness, we can therefore but say the more of it the better, and the size in a way may be described as perfect alike for the garden, the exhibition stand, or a lady's hair; all show it is one of those Roses that arrest, fix, fill the eyes of judges to the winning of first honours. Its form is also as near perfection as may be. True, perfect form, deep, finely recurved, reflexed, are a few of the phrases used indicative rather than exhaustive of its many merits. The petals also have a remarkably smooth finished character, having neither raggedness of edge, nor unevenness of surface. The petals, of which there are just sufficient without that suspicion of redundancy that tends to mar the symmetrical arrange-

ments of not a few Roses, are admirably disposed and delicately reflexed. In a word, the form of this fine Rose is most aptly described by the one word—exquisite. The substance of the petals is also good and substantial, and this quality adds an additional merit to the form of this fine Rose. It is the substance of the petals, in a word, that imparts that indescribable charm of massiveness that characterises many of our best Roses, which is most aptly described as sculptured. The difference between such Roses and those of the flimsier sort is as marked as that between rich velvet and tissue paper; the number, arrangement, colour, form of the petals may be alike or nearly so in two Roses, and yet the mere substance of the petals create the widest difference between the flowers. The colour of *Marie Baumann* is as brilliant as it is pleasing, and may be arranged under deep carmine, crimson, crimson-red, bright red, brilliant vivid red, so rich is it in pronounced tints and hues of colouring. Writing broadly, it may be said to be of the *Beauty of Waltham* type in general character of colouring. But the plate is so faithful in its colouring as to supersede the need of laboured description. From the leaves, however, being a trifle too light and the under surface of the upper two shown, the Rose looks a trifle darker than it is in Nature. The reflexed edge of the petals has also a silvern shade, which is well shown near the centre of the bloom. Altogether *Marie Baumann* is one of the most welcome coloured Roses either on the show stand, the garden, or for decorative purposes. As to the constitution of *Marie Baumann*, the authorities generally pronounce it vigorous. At the risk, however, of being called a croaker, it must be stated that this description must be received with considerable allowance. Vigorous it may be seen at times on the *Manetti* and also on the *Brier*, seldom or never on its own roots. It is also one of the most difficult Roses to strike root, and when this feat has been achieved it seems in no haste to multiply them. It is also one of those fine Roses that seems on the decline in regard to vigour. It appears less strong, and is assuredly less generally shown than it used to be. Brother rosarians whose experience is different will please inform all readers of *THE GARDEN* how to make this fine Rose grow so very vigorous as has been described rather than find fault with my record of truthful experience. Here with us it is neither a strong grower nor a long-lived Rose, which we exceedingly regret, as its qualities are of the highest, and it is held in great admiration. Can it be that beautiful Roses, like fair belles, have their season, short often, though brilliant, and then decline and fall like meteors, leaving but sorry or sad memories behind? Not that *Marie Baumann* has reached that stage, but is she as fresh and vigorous as she was? Roses also seem to have their localities. Roses that shrink from the arid air of the east may prove fresh as Daisies and fair as Lilies in the humid atmosphere of the dripping north. Could not the National Rose Society furnish rosarians with a geographical Rose chart crowded with blue stars indicating the localities where the blue ribbons of the Rose garden did their best? It possesses in the rich experience of its members material for such a valuable guide, and should see to its preparation and presentation with its next season's year book.

D. T. FISH.

A Rose odour.—I think I have seen in *THE GARDEN* at various times warm encomiums on the

scent of the Rose, the writers being evidently at a loss to find terms to do justice to its qualities in that respect, and throwing different varieties into groups marked by their scent. On approaching a very handsome double Austrian Brier this morning I found it had a strong smell of the common bed bug, and as I know of no section of Roses so distinguished among those described by your contributors, I thought I would name the matter to you. It was a very warm morning, and all the flowers had the same sickly smell.—NEZ.

ROSE GARDEN.

NOTES ON ROSES.

APHIDES, maggots, weakness, and suckers; these are but a few of the after blasts of the past March, for doubtless all these pests and other evils are either induced or aggravated by extreme cold. The correlation between aphides and frost-bites may be assumed to be well-nigh proved. Hence, as a rule, the more severely Roses are injured by frost in winter or spring, the more they are infested with these pests. Nor does this arise wholly from weakness, though the latter is a predisposing cause of insect attacks. But sap once frozen seems also sweetened. One of the simplest illustrations of this is seen in the honeydew and aphides that overspread tender Beech and other leaves after a chill. These two often come with such force, suddenness, and simultaneity, that it becomes a difficult problem to determine whether the aphides or honeydew are cause or effect. But our point here and now is that the sweetened sap intensifies the plague of aphides, and that the frost sweetens the sap. The same principle is illustrated in the freezing of Potatoes; and the writer knew one lady of a scientific turn of mind who has obtained the extra sugar she desiderated in this vegetable gratis by placing her daily supply out to freeze an hour or so before cooking. Her taste was peculiar—vitiated, it may be—but her practice merely gave prominence to the well-known fact that frozen Potatoes are sweet. And from this and other effects of frost on vegetable tissues it may be assumed that the fluids of Roses become sweeter through successive freezings, and hence, in part at least, the prevalence and power of aphides after such springs as the present. Be this, however, as it may, there can be no question that the only safe way with the aphides is prompt and immediate destruction. The rosarian who parleys with such an enemy is already as good as defeated. The weak insect of to-day grows into the thousand or ten thousand of to-morrow. The best weapon against aphides is the finger and thumb of the rosarian. While many are running to and fro for remedies, these promptly used will have vanquished all in sight. True, fresh battalions may arise from their ashes. But what then? Only this: up again and at them with the same primitive exterminators. The longer I grow Roses I have the less faith in nauseous dressings. Over large areas, and after the aphides are in full possession, Tobacco water, Quassia chips, hot sewage, smelling salts, snuff, &c., may be the only practical exterminators. But, taken in time, there is nothing to be compared with the simple mechanical grippers already named, which are also best as regards maggots. Sharp eyes and fingers, silent searches in the early morn or dewy eve, will result in heavy finds of these dismembering gourmands that so often bring consternation and create blank dismay among the ranks of rosarians.

APHIDES are bad enough, but they are mere light surface skirmishers, while maggots are the sappers and miners in the great army of destruction. Their destructive work is also so often done unseen, the finest buds and fattest shoots being, as a rule, chosen as the field of their nefarious operations; and yet practice begets wonderful perfection in maggot hunting. The experienced rosarian learns to track out and follow these disfiguring monsters with almost as much certainty as a hound a hare. But this knowledge only comes by patient practice and indefatigable perseverance. Nothing must be taken for granted in this war with the maggots, nor must any truce

be made. The Roses may be clean to-day and thickly infested to-morrow. The maggots seem as if they must have risen up out of the earth or fallen down bodily in showers from heaven. At all events there they are mining through the hearts of our finest buds, and not a moment should be lost in discussing the question of whence they come or whether they may be going, the one question of any moment being their immediate destruction. Fortunately, the severe spring comes to our assistance in this matter. The twenty or more degrees of frost several times repeated in March doubtless destroyed not a few maggots in embryo. By also reducing the area of our Roses it has rendered the task of maggot hunting easier and success in finding them more certain. And then, as to

THE WEAKNESS OF ROSES, so general in most places this year, the first step towards strengthening them consists in keeping them clean; the weaker, the greater need of the instant destruction of every insect. But there are other and more direct means of strengthening weak Roses. Yet another and very potent negative means of making weakly Roses stronger consists in lightening their load of blooms. If this is done in good time, it may almost be said that while the flowers lose the plant gains. It should, however, be done early, and in the case of very weak Roses it may even be prudent to remove the whole of the flowers for the sake of thoroughly re-establishing the future strength of the plants, but it will seldom be needful to proceed so far. No one need fear thinning their Rose buds freely. Apart from its re-invigorating effects on the Rose trees its beneficial influence on the blooms left suffices to commend the practice to rosarians. Unfortunately, few private growers can command sufficient time to carry out bud thinning with the skill or to the extent that it merits. So important is bud thinning on the quality of bloom, that it may almost be laid down as an axiom that those who thin best and most cut the best Roses either for exhibition or home use. When time can be found for thinning, no abnormally small, misplaced, or misformed buds should be left, nor yet any excess of even perfect buds, for one perfect Rose, like a perfect fruit, is worth three, six, almost any number of imperfect ones. But there are also more positive and direct modes of strengthening weak Roses. These consist in dressings of solid and liquid manure and mulchings of various sorts. A caution may well be given in regard to all such. Not a few rosarians seem to act on the principle that the weaker the Rose the stronger should be the stimulant. It need hardly be stated that this principle is wrong. It is about as easy to kill a weak Rose by an excessively strong stimulant as to blind one by an excess of light, and powerful stimulants need giving with a light hand to weakly Roses. Say, more; and in apparent contradiction to some of the highest authorities on Rose growing, I would venture to affirm that, as a rule, not a few stimulants are so overdone as to do far more harm than good. Weakly Roses should have mild stimulants in small doses at first, and only after growth is re-established and in full vigour can strong stimulants be given to any good purpose. Hence in many cases mere mulchings, that is ground coverings, with non-manurial or very slight manurial dressings, are more useful than heavy dressings of rich or solid manure. These mulchings conserve the goodness already in the soil, preserves it in a suitable state for the use of the plants, and surrounds the latter with such physical conditions as enables them to utilise it to the highest advantage. And this is a good deal more than can be affirmed of not a few of the favourite manures given to Roses. No doubt Roses are gross feeders, but possibly they are less gross in their root tastes and powers of assimilation than many assume. While it is certain that not a few liquid and solid manures may prove too fresh and strong to be absorbed or positively injurious,

ROSES IN FULL GROWTH can assuredly appropriate large quantities of manure, but those in a weakly state cannot thus be forced into strength

at the point of the manure fork. Suckers have seldom been more troublesome than this year. These are also one of the fruitful legacies of the frost bite in the spring. Top-growth being crippled or destroyed, the roots have sought erratic out-growths of pent-up vitality, and found it ready to hand in crop after crop of suckers. Where these cannot be utilised to advantage, by forcing into fresh plants or conversion into rooted cuttings for budding on, &c., they should be persistently destroyed so soon as they appear, for few more sure recipes could be given for the sudden destruction of crippled Roses than to allow a rival crop of suckers to divert the root supplies away from their already impoverished root-stocks or branches. On the other hand, by keeping the suckers vigorously suppressed, the vital force left in the Rose plants will be more likely to find its way to where it will prove of most service to the growing buds and the future strength and longevity of the Roses.

D. T. F.

NIPHETOS ROSE BEST ON OPEN WALLS.

IN houses and on warm walls this has been very truthfully described by one authority as a Magnolia-like Rose. The comparison is as apt as it is happy, and we have but to fancy a Magnolia grandiflora reduced in size and grown into a double flower to realise the stately wax-like character of the Niphetos Rose. The white has often that dash of lemon in it that is also a characteristic of the Magnolia. The Niphetos is, however, the more perfect and useful when it is white as the driven snow, as its name imports. And yet though few, if any, have noticed it, something like a distinct charm is added to this most perfect Rose when a few of the outer or enveloping petals are suffused with pink, and occasionally with a deeper tint approaching crimson. This is generally confined to the upper ends of the surface petals, and is all the more telling in contrast with the mountains of snow underneath. And truly the petals on petals *ad infinitum*, piled one upon another in such grand masses, almost deserve the name of snow mountains. The form may be best described as classical, there being such a chaste touch and perfect finish about the exquisite shape of this fine Rose either in bud or when more fully expanded. Perhaps it is the purity of its whiteness and the perfection of its exquisite form that gives the finishing touches of grace and beauty to this most distinct and beautiful Rose. One thing, however, it nearly lacketh—that is, fragrance. Its scent is mild at the strongest, though pleasant and also distinct, having that suspicion of sweet air and fresh milk that reveal themselves in greater fulness in some other Roses, notably *Boule de Neige*. Niphetos is generally described as of vigorous growth; I do not find it so. To have described each shoot as terminating in flowers, and these flower-shoots as refusing to push growing shoots, would have been nearer to our experience. Exceptional cases may be met with, but, as a rule, Niphetos is by no means the Rose to cover a roof, rafter, or wall rapidly. The pronounced character of its floriferousness militates against it and is in inverse ratio to its growing power. Even cutting back hard does not always obtain the vigorous growing shoots desiderated; but with the hope of thus obtaining fresh material for filling spaces and clothing wall or roof areas, as well as for cultural reasons, Niphetos should be grown on its own roots. A lighter compost than that given to other Roses seems to suit Niphetos; and, while it will grow fairly well in ordinary compost, it grows more freely in one containing a liberal percentage of leaf mould or peat. With healthy well-established plants in a house heated so as to command a temperature of from 55° to 65° all the year round, Niphetos alone will well-nigh solve the problem of a fresh Rose bud in flower every day throughout the year. To ensure this, however, every bud or bloom should be cut as soon as perfect, and the cutting back of the shoot or otherwise be attended to at the time of cutting. Nothing assists continuous blooming like this perpetual pruning. On the open wall Niphetos should be protected in winter, and seldom flowers freely more than once in the

season. The outer petals are also much more suffused with colour out of doors than in. So marked is the difference, that indoors nearly all the flowers will be spotlessly white; out of doors the majority may be stained with pink. The most magnificent flowers of the Niphetos are, however, mostly gathered from the open air. Hence, wherever space can be found on a warm south or west wall, part of it should be devoted to the Niphetos Rose, for no Rose is more enjoyable in the garden, few or none more valuable for bouquets, wreaths, the furnishing of vases, &c. Nor in the latter connection must the very superior foliage of Niphetos be forgotten. The leaves are large and smooth, and go admirably with the blooms. The flowers match admirably with Gardenias, Tuberoses, white Lapagerias, Orchids, Stephanotis in wreaths and bouquets; in fact, Niphetos Rose is strong enough to hold its own with any flowers however choice, and can afford to give a little support when and where needful to the best of them. Medium-sized, half-opened flowers are also the most perfect of button holes. D. T. F.

SEASONABLE WORK.

FLOWER GARDEN.

RHODODENDRONS.—All seed vessels should be picked off the earlier varieties, straggling shoots pruned in, and grafted kinds examined with the view of removing stock shoots and root suckers. Any plants moved in the autumn and winter should still be kept mulched, a condition that will obviate the necessity of watering. This remark also applies to all other kinds of shrubs that have been lately transplanted, though no doubt some would be the better for having a good soaking of water as well as the mulching; any that look critical, and must be saved at any cost, should at sunset be syringed overhead. Lilacs, Spiræas, Weigelas, Broom, Gorse, and others done flowering should, if needed, either through restricted space or to ensure the keeping of the plants equable as regards growth, be pruned into the required form. Keep the clumps free from weeds by means of surface hoeings as often as an opportunity offers.

ROSES still need a large amount of attention as to cleansing them from aphids and maggots; copious waterings in dry weather and surface mulchings, which keep the plants in vigorous health, will do much to prevent the attacks of parasites. Climbing Roses should be kept well secured to their supports, and the old flowers should be regularly cut off, an operation which will assist in the production of a second bloom.

CLIMBERS.—Keep Clematises and other climbers closely trained in; these also need plenty of water at both root and top, more particularly those plants that are growing close to buildings and under over-hanging protections where the rainfall cannot reach them. Supports should be placed to Sweet Peas, Scarlet Runners, Canary Creepers, Convolvuluses, and every other kind of annual climber before there is any risk of the growth getting matted. Such plants are alike useful for festooning or drooping over ledges of rock or root-work, but even in these positions it is necessary to occasionally go over them to single out and if needs be to cut away portions of their growth.

GENERAL WORK.—This will consist in finishing bedding out and in the removal of every trace of untidiness that for a time is unavoidable whilst such work is in progress. Trim or peg into form every kind of plant that will look the better for such manipulation. Pinch the flowers of Calceolarias, Violas, Verbenas, Petunias, and Pelargoniums to ensure their early and more vigorous establishment in the soil. The flowers of Lobelias and carpeting plants we prefer to remove with a pair of sheep shears, which at the same time take off any uneven portions of the plant, the growth afterwards being more dense and tufty. In the early stages of growth, Alternantheras and Coleus quickly resent artificial watering by refusing to

grow at all; preference should therefore be given to mulching the beds with Cocoa fibre refuse; this renders all waterings, except the first to settle the plants in the soil, wholly unnecessary. Mowing of lawns and weeding of walks are now at the maximum point, and with the stinted labour, now common to most gardens, it is difficult to keep abreast with such work; where this cannot be done without neglecting other and more important departments, it would be well to consider whether or not it would not be wise to reduce the amount of ground that ought to be highly kept to such limits as the labour allowed would be able to maintain in perfect order.

FLORAL DECORATIONS.

HAVING occasion recently to arrange a centre-piece for a dinner table of considerable size, we selected a glass vase with a single cornucopia rising from its base. Its height was about 24 inches, and the bottom measured about 12 inches in diameter. About the latter we placed a fringe of Fern fronds of such sorts as *Adiantum formosum*, *Nephrodium molle*, and a few only of the golden and silver *Gymnogrammas* with the fronds inverted, Moss being used to cover the sand. Around the stem were placed three or four growths each of *Cyperus alternifolius* and *laxus* of various heights; interspersed with these were ten or more fine spikes of the Turk's-head Grass (*Lagurus ovatus*), all standing as if growing. Several fronds of Maiden-hair Fern were arranged as an undergrowth. After this the flowers were added. These consisted of three blooms on their spikes of the German Iris, with about a dozen flowers of *Gloxinias* with all the length of stem we could secure; dotted amongst these were five or six blooms of the yellow Paris Daisy (*Etoile d'Or*) and a few trusses of a pale *Bouvardia*. This completed the arrangement of the base, which rested on the table-cloth. In the cornucopia was placed a slender spike of a small form of *Delphinium* (blue) and three spikes of *Astilbe* (*Spiræa*) *japonica*; dotted here and there were pink and white *Rhodanthe*, and overhanging the margin of the trumpet, spikes of *Begonia odorata* resting on a fringe of *Pteris serrulata*. This completed the arrangement. It will be observed that single flowers only were used, and a very pleasing effect was obtained by means of them; in fact, the addition of any double flowers of any sort would have marred the effect of the whole. Two small plants of *Cocos Weddelliana* were placed in two soup plates without being turned out of their pots; sand was placed around each and covered with Fern foliage and variegated *Begonia* leaves. A few blooms of *Roses* were then interspersed among these, no other flowers being used. These arrangements were placed on either side of the centre, and on each side of these was a well-bloomed plant of *Gloxinia* in a vase. The *Gloxinias* were, if anything, too heavy; a smaller plant would have been better. The same day an experiment was tried with some blossoms of *Passiflora kermesina*, having several open. We cut them early in the morning and allowed them to float in a basin of water till the evening, when they were placed in a small glass for the drawing-room. In this manner they kept perfectly fresh and open; had I left them on the plant, they would have closed before I wanted to use them.

INDOOR PLANTS.

KALOSANTHES.—Young stock of these should be propagated yearly. They strike readily; in fact, cuttings will root if merely laid on the surface of the soil in a greenhouse or pit. The best way is to put single cuttings into small pots filled with ordinary loam and sand, selecting from established plants moderately strong shoots that have not set any flowers. These will root in a fortnight if kept a little, but not too moist, as succulent plants of this kind if too wet in the cutting state are liable to rot. In preparing the cuttings all that is necessary is to make a clean cut at the base, and to strip off the leaves of the lower portion that is inserted in the soil. When

well established in small pots move them into others about 4 inches in diameter, which will be large enough for this season. They will make good flowering plants in two years. During summer they will succeed in an ordinary greenhouse or pit, giving them enough water to keep the soil in a healthy condition. *Kalosanthès* are amongst the easiest of all plants to manage, but it frequently happens that they do not flower freely; where this occurs it is the fault of the treatment. All that is requisite is to get the shoots properly ripened the summer previous to that in which they are intended to bloom. This can only be done with certainty by setting them out of doors exposed to full sunshine for a considerable length of time, say from the beginning of July to the middle of September. To have the flowers highly coloured the plants require to be placed in the open air just before they begin to open. The north side of a wall where they will get plenty of light, but not exposed to the mid-day sun, answers well.

INDOOR ROSES.—Where these are planted out they will not require nearly so much watering as when in pots, but care must be taken that the beds they occupy are not allowed to become too dry, or the foliage will be sure to be attacked by mildew, and the crop of flowers will be much reduced both in size and quantity. It is the more necessary to see to this, as the daily use of the syringe keeps the surface soil moist, whilst that underneath may be dry. When the plants are strong and making vigorous growth they require to be well supplied with manure water. Tea varieties, which are much the most suitable for indoor cultivation, are all but continuously in a growing state the whole year round, and to maintain their vigour they must have the soil regularly assisted in this way, or else have the surface dressed with some light manure that will be washed down in the operation of watering. The same applies to pot *Roses* that have been started in succession to follow the winter bloomers. Where a house is devoted to *Roses* it is desirable to keep the plants on in a flowering condition, even after a supply can be had out-of-doors, for in many localities the Tea varieties seldom produce flowers in the open air that will bear comparison with those grown under glass. Plants that have given two or three crops of flowers during the winter and spring will now show signs of requiring a rest, however strong they may have been, but on no account turn them out in the open air until they have been somewhat hardened off by discouraging growth through cooler treatment. Even in the case of such plants as are being thus subjected to a resting process, whenever mildew appears it should at once be checked by the application of sulphur.

HERBACEOUS CALCEOLARIAS.—Where a good strain of these exists and they are well grown they will have been very effective. Any that show marks of superiority in habit of plant or form and marking of the flowers should be placed by themselves and kept for purposes of propagation, as well as for seed saving. By selecting individual plants in this way the strain may be continually improved, but in all cases remember that a vigorous, healthy constitution is of the first importance, so that the plants are able to make plenty of stout foliage, for without this the flowers, however perfect, are of no value for general decorative use.

CELOSIA PYRAMIDALIS AND BALSAMS.—Another sowing should at once be made of these, the produce of which will bloom later on after the earliest are over. Where there is a good strain of this elegant feathery *Celosia*, comprising the brightest shades in yellow and pink to deep crimson, and the plants are well managed, there is nothing more beautiful. The small side branches of the flower-spikes are most effective when mixed with any combination of cut flowers. The length of time during which they will last either in a cut state or on the plant is not the least valuable property which they possess, but to prevent their getting tall and leggy, they should from the time when the seedlings first vegetate be subjected to plenty of light

and receive as much air as can be admitted without the atmosphere of the house or pit being too much dried up. The same applies to Balsams. Where these are allowed sufficient head room with timely shifts into pots big enough to admit of due extension of the roots they have a very different appearance from the starvelings too often met with. Both the above plants enjoy a liberal application of manure water after they have begun to go away.

ORANGES.—Where these exist in either small or large examples, and the greatest quantity of flowers, which they can be made to produce are wanted, they should not be allowed to bear fruit, as when the plants are in good condition and kept a little warmer than in an ordinary greenhouse, they flower oftener than when their energies are overtaxed by fruiting. Whilst in full growth the plants should have frequent applications of manure water, in which soot ought to be an ingredient, as it is distasteful to worms usually so troublesome in the soil. Where Oranges are grown in more or less warmth one of the principal things requiring attention is keeping down scale and mealy bug. Where these pests are allowed to get numerous before means are taken for their destruction the foliage always suffers in a way that makes them unsightly, and the free production of flowers is also impaired.

FRUIT.

PEACHES.—Early houses from which the gathering of ripe fruit was commenced in May require very careful management to keep the trees in a vigorous state of health for a number of years, and as the replanting of a house is attended with considerable expense, too much care cannot be bestowed on large, healthy trees from the time the last Peach is plucked until the leaves fall early in autumn. As lean-to houses are best adapted for early forcing, movable lights are preferable to fixed roofs, particularly where gardens stand high and airy, and the borders, as all early Peach borders should be, are confined to the interior of the house. When all the fruit is gathered from the earliest trees, cut away all superfluous wood which has been retained for the benefit of the crop of the current year; remove breast-wood, and tie in the shoots left, allowing plenty of room for the full development of the foliage and the free admission of light and air. Syringe well to clear away insects which may have gained a foothold, and water with tepid water until every part of the border is properly moistened. Tie down the shoots in succession houses, and shorten back to increase the size of the fruit where the wood will be no longer wanted after it is gathered. Gross shoots from behind, as well as in advance of the fruit, which will be expected to produce the next crop, may also be pinched and the final thinning of the fruit completed, as healthy trees are often injured by being overloaded through the trying ordeal of stoning. Give plenty of water of a stimulating nature to inside borders. Syringe early and well with clear, soft water. Ventilate freely through the first part of the day, and assist the fruit through the last swelling by closing in good time with plenty of sun heat. Trees in late houses require more decided disbudding than is sometimes bestowed upon them, as it often happens that the fruit in these structures is kept back until many of the wall Peaches are over, and the wood of such kinds as Barrington and Walburton Late Admirable does not get properly ripened. Growers of late Peaches who have not planted Sea Eagle will do well to give it a trial. With me it yields very fine fruit, which keeps a long time after it is gathered, and, unlike the Barrington, it always completes its last swelling and finishes properly.

WALL FRUITS.—The wall culture of fruits of any kind for market is by no means well done, the expense of walls and the uncertainty of tenure rendering it impossible for the tenant to properly carry it out. Walls, however, would well repay the expenditure bestowed on them; not only could choicer kinds of Pears, Cherries, Peaches, Plums, &c., be produced on them, but they would

also shelter other crops; in addition to the greater certainty of crops that shelter walls would give, there is a still greater one of getting the produce from their immediate vicinity into market a few days before that in from open quarters, and every one in the market trade knows that a few days even frequently make all the difference between profit and loss in the case of any crop. Walls of the massive character one finds in private gardens would not be needed; wooden framework covered with stout felt, as one finds at Barham Court and in other experimental fruit gardens, would answer, and would not cost much—a great point in fruit culture for market.

ORCHARD HOUSE.—Remove the early kinds of Peaches to a cool part of the house or a separate house altogether as they are cleared of ripe fruit. Thin out the wood from which the fruit has just been gathered, stop exuberant growths, and syringe well to free the foliage from spider. Vigorous young trees which require a shift into larger pots may either be potted as they are cleared of fruit, or they may be kept well supplied with water of a stimulating nature until the whole of the first batch is ready for overhauling. Keep them under glass and maintain a moist, growing atmosphere until the roots have taken to the new compost; then plunge in ashes in the open air, mulch to economise watering, and syringe overhead on fine evenings. Pay particular attention to the watering and syringing of all kinds of fruit trees in mid-season and late houses, and make sure of the water reaching the roots of those planted in the borders by mulching or forcing a basin round the stems. The best time to ascertain whether a tree wants water is just before the afternoon syringing, when a glance at the pot or the foliage will tell whether the roots are dry. Make the final thinning and shorten back the shoots where a sufficient number of promising fruits are swelling near home, and the shape of the trees can be improved thereby. Let the trees be well syringed soon after six on fine mornings, and not later than four in the afternoon. Open the ventilators when the temperature begins to rise, and let the time when the fruit is wanted be the guide in closing for the day. Late or unheated houses, which now in many places give a more certain supply of fruit than can be obtained from open walls, may from this time forward have the ventilators left constantly open until the fruit is ripe. An erroneous opinion prevails with some that house Peaches ripen earlier than they do on walls, but if judiciously selected kinds are potted, or, better still, planted out, and a constant circulation of air is maintained, with due attention to atmospheric moisture, fruit equally late and of finer quality may be secured.

KITCHEN GARDEN.

EARLY Potatoes should now be earthed up, and if this operation can be done after a night's rain, they will be made almost independent of the weather, the soil added to the rows and the foliage together making a capital mulch. Early Broccoli raised under glass should now be pricked out. We use 2 inches of Mushroom manure and a thin layer of soil, placing them in the alleys left for fruit trees by the side of the wall—generally a west one. The bottom under such circumstances is hard, and the Broccoli does no harm for the short time it requires the ground; in fact, in dry seasons the mulch actually benefits the wall trees. The Mushroom houses should now be thoroughly cleaned out, removing all the old beds; sweep down the walls, and give them a good syringing, and when wet sprinkle them and the path and roof with fresh lime, opening all ventilators, doors, and windows, so that a sweet house may be the result. Mushrooms more than anything enjoy a pure atmosphere. Outside beds are bearing here very well. Keep them damp by watering the covering of the bed, letting the water soak through the straw slowly, but surely. Tomatoes should now be planted out; bear in mind they want a good sound loam, but not much manure. It is a ques-

tion whether we do not, as a rule, use too much manure. If Tomatoes require any assistance after the fruit is set, they will tell you by their looks; and if so, give them a couple of good waterings, either with manure water or guano; 1 lb. of the latter to 36 gallons of water is sufficient. Keep a good supply of Lettuces tied up and plenty of small salads sown.

MARKET GARDEN NOTES.

CARROTS.—A recurrence of such seasons as the past would have the effect of seriously diminishing the area devoted to Carrots in this neighbourhood. I think the oldest grower of them would be ready to acknowledge that never in his memory have prices ruled so low as during the last winter and spring. In former years there was much grumbling if they came down for a time to 3s., or perhaps occasionally to 2s. 6d. per dozen bunches; now many would have been glad to have secured even such moderate prices as these. Two shillings per dozen has been a common price this season, and I have known many loads of good "ware" sold at 1s. 9d. per dozen, and from this has had to be deducted salesman's commission. No one can grow Carrots at this price; it does not return expenses. A large grower once told me that 2s. 6d. per dozen only just barely paid him, allowing for wear and tear of "tackle." The Surrey Carrot growers have probably had their best time, and I should in no way be surprised if a few years saw the extinction of the trade in "bunched" Carrots. It has often been said that Londoners only please the eye in the way of fruit and vegetables, and care but little for flavour. To a great extent this is true; but within the last few years they appear to have learnt a wholesome lesson in the matter of Carrots, and now buy, and even prefer, the unbunched Intermediate or bushel Carrots which the Essex men have been pouring into the London market in an annually increasing quantity. This is as it should be, as hitherto consumers of this vegetable have been paying for the bunching and general get-up of the "long Surreys," and have, in the bargain, eaten an inferior article. Their eyes are now opened to the truth, but a heavy blow is thereby dealt to the Surrey men, who can never again hope to make the money they have done.

TURNIPS.—Winter Turnips are mostly sown in this locality early in July on ground which has remained fallow from the preceding autumn, but they are one of the most uncertain crops as regards paying with which I am acquainted, sometimes selling well, at others being almost or quite valueless. Very much depends upon the weather generally at sowing time, as if not moist the young plants get the "fly" and come to little good. Then, again, a good year for Potatoes and a mild winter in which green material is abundant is all against Turnips, and at such times many loads are sold for a trifle to London cowkeepers. Sometimes a good hit is made, and I know men who have made a lot of money with Turnips in one season. Some years ago a friend of mine made up his mind to grow Turnips largely and allowed a considerable extent of land to lie fallow for the purpose. It happened to be a very dry summer, one of the driest on record, no rain falling from April till July, and, curiously enough, the only moist weather that occurred before September came just as the seed was got in. The consequence was that it germinated well and produced good crops. Now as this individual had sown earlier than is the custom to do, and dry weather came again in the course of ten days or so, he had a good plant whereas those who sowed at the ordinary time failed; in fact the Turnip crop that year was a general failure. Turnips were, therefore, scarce, especially early in autumn, and my friend told me that he made enough from three fields of them to pay the whole year's rent of his farm. Such good fortune as this does not fall to the lot of many; still, such cases do occur from time to time, though growers here assert that they will soon be recollections of the past, and that the "good

old times" of the Turnip trade are over. This may be the case, but I am inclined to think that the uniformly moist summers we have experienced during the last few years have mainly influenced the prevailing low prices, as they have been favourable to the germination of the seed and after-growth of the plants. Hot, dry seasons would undoubtedly send up prices again, and there would be more scope for forethought, skill, and individual enterprise. The following instance will illustrate my meaning: During a time of exceptional drought, and when the ground had become very hard and dry, so hard, indeed, as apparently to preclude the practicability of working it, a grower here determined that by some means or other he would break up some of his fallow land in readiness. He did so, and, strange to say, there came a heavy thunderstorm, which loosened the clods, so that the harrows were put on and the seeds got in directly. No more rain fell, but the seeds being put in the moist earth came up well. The Turnips thus obtained were the first in the market, and were sold, many of them at fancy prices, owing to the lengthened scarcity caused by the very hot and dry season, and the major portion was disposed of at six shillings per dozen bunches, an excellent price for Turnips, which do not cost near the money to grow than Carrots do. The latter require experienced hoers and to be gone over three or four times, whilst Turnips may be taken in hand by any ordinary labourer, requiring only to be "flat boed" once and cut out a week or so later.

LATE PEAS.—One would naturally suppose that no market grower would be likely to commit the error of sowing late crops of Peas on light porous soils, and yet I saw this done last year, and, as may be conjectured, the results were by no means satisfactory; hot weather setting in just as the pods were forming, but a small percentage of them filled, and it is doubtful if the crop paid the working expenses. The piece of land where these Peas were grown would have been admirably adapted for an early crop of some kind, say Potatoes or Peas, but for a late crop of Peas which can only be brought off under very good culture it was quite unsuitable. Late Peas should never be grown by those who may not have good deep loamy or holding soil wherein the roots can find plenty of good moisture when the pods are filling out. Better far grow things for which the soil is naturally adapted than attempt the culture of such as can only come to anything like perfection when the season happens to be exceptionally favourable. J. C. B.

RECENT PLANT PORTRAITS.

BOMAREA PATACOCENSIS (*Botanical Magazine*, plate 6692).—Already figured and described in THE GARDEN under the synonym of *B. conferta*; now re-named from the place where it was first found—Patacocha, in Ecuador, at a height of 6000 feet above sea level. A truly noble and conspicuous flowered cool house trailer.

ANGRECEM MODESTUM (*Botanical Magazine*, plate 6693).—A small pure white-flowered Orchid from Madagascar.

GERARDANTHUS TOMENTOSUS (*Botanical Magazine*, plate 6694).—An insignificant small yellow-flowered Cucurbitaceous trailer from Natal, forming enormous tubers, one of which was found to measure 6 feet in circumference and to be nearly 2 feet thick, with but one fibrous root about half-an-inch in thickness. From the centre of each of these huge tubers springs a single stem of not more than three-quarters of an inch in diameter, thickly covered with small round tubercles, which ascended without a leaf to the top of trees 50 feet in height.

CLERODENDRON MACROSIPHON (*Botanical Magazine*, plate 6695).—A very elegant stove shrub sent from Zanzibar in 1881 by Sir John Kirk, with bunches of pure white flowers borne on long tubular stems, and from which protrude long and conspicuous purple threads of the filaments. It was found on the coast opposite Zanzibar Island in very rocky places, where it formed a small, slender shrub.

CEPHELIUS TOMENTOSA (*Botanical Magazine*, plate 6696).—A very singular plant from Guiana, congeneric with that yielding the medicinal ipecacuanha, but of very different appearance. Also known under the names of *Callicocca* and *Tapogomea tomentosa*. Flowers small, white, with red involucre.

ACER INSIGNE (*Botanical Magazine*, plate 6697).—A handsome Maple from Persia, said to be the hardiest of the eighty species and varieties of this family cultivated by Mr. Van Volxem, from whom it was received. It is conspicuous in late spring for the size and beautiful scarlet colour of the bud scales and for the tender green of its pale foliage. Also known as *A. velutinum*.

The first number of the *Paris Revue Horticole* for June contains a portrait of two tuberous Begonias named Edouard André and M. A. Hardy, raised by Messrs. Couturier & Robert, of Chatou, near Paris. Both these varieties are large and somewhat coarse flowers, especially the second named, and though bright in colour, cannot, I think, be deemed an improvement on some of the fine varieties already in cultivation. W. E. G.

FLOWER GARDEN.

POPPIES AND OTHER HARDY PLANTS.

I EARNESTLY hope that Mr. Wolley Dod has strong shoulders, as he has had to bear my sins (horticultural, I mean) in the matter of *Papaver umbrosum*. I suppose Messrs. Carter overlooked his letter in your issue of May 26, in which he repudiates the mistake I fell into in supposing he told me that Poppy was yellow. I fully recant, and cannot think how I can have imagined (as I certainly did) that he had been guilty of heresy. I am at issue with Messrs. Carter about the colour of *P. orientale*. They call it crimson; I say it is orange, or a very, very orange shade of scarlet. I call *P. bracteatum* crimson, or a lively cherry colour; that is, if the Poppy I have is *P. bracteatum*. I send you a bloom, and I am sure you will agree with me that a more magnificent flower does not exist. It measures 13 inches from tip to tip if you spread out the petals. I saw a similar Poppy exhibited last year at the Royal Horticultural by Messrs. Barr & Sugden, but it was not so large as mine, which, however, has certainly had very high culture. There are seven flowers on my plant. The stems, about 4½ feet high, are raised far above the foliage, which is much more feathery and less dense than *orientale*. I remember this Poppy for more than thirty years. It was usually, but I suppose incorrectly, called *Crimson Oriental*. It is extremely difficult to transplant; its roots go down interminable depths in the ground, and it was years before I succeeded in procuring a bit that would live. I shall be glad to hear whether you consider it to be the true *bracteatum* or a variety. [It is the true *P. bracteatum*.]

I have tried this year *Empress Anemone* and *Cockade Ranunculus*. The first is a fine, large, sturdy variety with very large flowers. I have, however, been unfortunate in my colours, which have been nearly all white and a washy lilac. The *Ranunculus* is, I think, simply the old *Meladore*, a pretty border variety, but far too single, or rather semi-double, to be worth much as a *Ranunculus*. I like and value it because I do not own a *Ranunculus* soil. I cannot make either the Turban or the Persian to do at all with me, but asiaticus, which I procured along with the above from Messrs. Carter, does fairly well.

About thirty years ago my mother procured from the Grand Duke of Tuscany's garden at La Petraja, Florence, a magnificent collection of *Meladore Ranunculuses*, every shade of colour as double as a Persian and four times the size. I never saw anything like them anywhere before or since. They were most hardy and vigorous in growth, but little by little they degenerated, and at last after about sixteen years they became as semi-double as those I know have from Messrs. Carter, and, curiously enough, they almost all turned to a pale faded lilac colour.

If any of your correspondents can and will tell me where I can purchase *Meladores* like what these were at first, I will call them virtuous Christians, and feel a deep debt of gratitude to them. They are not, I fear, to be procured now at La Petraja, as I have frequently asked friends staying at Florence to procure roots for me, but they have invariably brought me Persians. *Virginia Rectory.* DENIS KNOX.

ERIGERON AURANTIACUM.

THIS new golden-flowered composite may be regarded as one of the best border flowers introduced for a long time, as it supplies a new colour among plants of a similar character. It is dwarf, seldom being more than a foot in height, compact in growth, and all its parts are more or less hairy. It appears to be extremely floriferous, even small plants of it bearing numerous flowers. It is a

Erigeron aurantiacum, showing habit of growth. Flower about one-half natural size.

native of the high mountain ranges of Turkestan, whence it was first introduced by Dr. Regel, of St. Petersburg. It is quite hardy, of as easy culture as the rest of the species of *Erigeron*, and is propagated readily by division or seeds. It forms at present one of the most interesting plants in flower in the Hale Farm Nurseries, Tottenham. Seeds of it are obtainable from M.M. Vilmorin-Andrieux & Co., Paris. A year or so ago Messrs. Veitch obtained a first-class certificate for it when shown at the Royal Horticultural Society's meeting at South Kensington.

NEW OR RARE PLANTS AT BADEN-BADEN

ARCTOTIS SPECIOSA is a fine consort to *A. aspera* and *aureola*; its flowers are deep yellow, finely contrasting with the blackish disk. *Papaver speciosum* is also remarkable; its appearance is much like *Meconopsis nepalensis*; the flowers are 4 inches across and of an apricot colour; it stands the sun well. Rockets of the dark purple and of the rose-flowered kinds are very fine; the latter, however, are always rare. *Primula sikkimensis* of the fine large-flowered strain introduced by Mr. Elwes is very showy; the gracefully pendent bells vary in colour from straw to canary-yellow. A tiny little gem is *Primula sapphirina*, only 2 inches high, with small shining sapphire-blue flowers. A striking plant is *Codonopsis ovata*, a rare perennial of the Campanula type; the numerous flowers are of a greyish blue, with some orange blotches inside the bells; they expand in quick succession for some length of time. *Psoralea subcaulis* is a nice plant from the United States, belonging to the Leguminosae; it bears a strong resemblance to an *Astragalus*, and the flowers are of a pleasing deep violet colour. *Delphinium triste*, with its nearly black flowers,

though an old plant, is now-a-days scarcely to be had. *Centaurea pulcherrima* is showy with its deep rose flowers. *Silene tatarica* is a fine and desirable plant; the spikes are well beset with pure white flowers, and though only 6 inches to 8 inches high, look very massive and pleasing. *Eriogonum compositum* is a showy, though dull white-flowered sort. *Phlomis armeniaca*, though not a prominent beauty, nevertheless deserves room in a good collection; the small rose-coloured flowers stand in superposed whorls; six whorls flower at the same time, and its habit attracts attention; it is rather tall, about 3 feet in height. *Salvia hians*, the good variety figured lately in the *Botanical Magazine*, is as showy as *S. interrupta*; the flowers of both are of a shining blue with white lips. *S. interrupta*, however, is not hardy, whereas *S. hians* is. Some years ago an English officer picked up seeds of an Afghanistan *Eremurus*, which were sent to the Royal Gardens, Kew, and I was favoured by the authorities there with some seeds, from which I obtained a batch of seedlings. These have been carefully grown on, and are in flower now. Considering every quality, I may fairly state that this is the most beautiful species I have ever seen. The spikes are about 1 foot in length, on graceful stalks 3 feet in height; the flowers are of a bright deep canary-yellow, with anthers of a soft cinnabar red colour blending harmoniously with the shining yellow. It will soon, no doubt, receive a name. MAX LEICHTLIN.

Baden-Baden.

AURICULAS.

THE discussion about florists and their flowers may give the impression to the majority of your readers that show Auriculas are greenhouse plants, and are forced artificially by heat for the exhibition table. "Peregrine" endeavours to give this impression to the uninitiated in last GARDEN (p. 483), while as a professional gardener he must know that a forced Auricula could not possibly win, and that florists do not force their plants at all. A few general remarks, therefore, may be useful at this time.

ALPINE AURICULAS, which are perfectly hardy, can be readily raised from seed, and if care be taken to obtain really good seed, it will be found to produce a large proportion of really good flowers, and occasionally there will be found a few worthy to take their position as show varieties. The market gardeners about Sale buy the very best German seed, and from this are raised many beautiful laced and shaded Auriculas of great beauty and value for the open garden. When the seedlings are sufficiently large they should be planted out in light soil, either on rockeries or in the open borders. In sandy soils such as you find in the gardens at Southport the Auricula grows into large mats a yard across, and appears to live for years. I believe it is only on heavy damp soils that it is apt to die off, more from damp than from cold. The show varieties of alpine Auriculas are similar to these, and are generally grown in open frames, the lights being only used in wet weather. They are quite hardy, and if the surplus plants are planted out in light soil and airy situations they will live for years.

SHOW AURICULAS.—These, of course, are valuable plants, and require care commensurate with their value and importance, but they are still hardy and require alpine treatment. How can this be best accomplished? For many years they have been grown in frames, but these are imperfect, especially in continued rains and frosts, because it is impossible to examine plants properly at such seasons if you cannot have proper access to them, and it is just now that they are apt to damp off if the atmosphere is close and saturated with moisture, and losses are certain to follow. It is, therefore, best to grow show Auriculas in glass houses specially constructed so as to give the greatest possible amount of fresh air to preclude damp, and to keep out frost at blooming time. The glass should be as near the plants as possible, and the pots plunged in dry cinders, so

as to require watering as seldom as possible. In my own Auricula house I can introduce hot water by a 2-inch pipe, which will keep the temperature at 40° in frosts. This is all the forcing the plants get. From June to October the whole of them stand out upon a bed of ashes in the open garden on the north side of a Beech fence, where they get the morning and evening sun, and rest during the summer and autumn. During this time they get repotted, and if heavy rains prevail over a long period, we cover the plants with lights, so as to ward off the evil effects of damp. Towards the end of October they are moved into the Auricula house, where they are finally top-dressed just before the awakening in February for the blooming in April. Here they can have daily attention and careful watering, neither too much nor too little, as the season and the wants of the plants require. If after February hard frosts occur we use very little heat, keeping the frost out and no more. We carefully exclude east winds, but at all other times the utmost amount of air is given during the daytime, unless the air is fog or damp laden. It will be seen, therefore, that an Auricula house fulfils as nearly as practicable in our damp, cold climate the conditions which are imperatively required for alpine plants. There is no forcing whatever, unless perhaps as the exhibition day draws near you put a plant for a night or two in a greenhouse to help the flowering. But even here forcing is prevented by the rules of our Auricula Society, as *your plants must be shown without artificial supports*; and if you were to force an Auricula truss, the stem would suffer in sturdiness, and you would fail in your object. There is no plant which can be forced less successfully than the Auricula, and I think if a florist can succeed with it he can grow anything.

WILLIAM BROCKBANK.

Brockhurst, Didsbury.

FANCY PANSIES.

IT may be remarked with truth that everyone who cares for Pansies makes much of the large striking fancy varieties. They may be said to have originated some twenty-five years ago, or, at least, to have then first awakened the interest of English cultivators. To the French florists belong the merit of effecting a marked improvement in this class. In 1858 they sent us *Eva*, *Pobo*, *Floribunda*, *Cerberus*, *Cerulea alba*, *Eckhard*, and others; in 1859 they sent us *Prince Imperial*, *Ali Bey*, *Parpaillot*, *Miracle*, *Agnes Sorel*, *Napoleon III.*, and *Masaniello*, all of which I have seen in good condition in Yorkshire. In 1860 there came across the Channel a batch showing plainly that considerable headway was being made, and I remember well how much we were delighted with *Belle Esquemoise*, *Louis Miellez*, *Distinction*, *Leviathan*, *Princesse Mathilde*, *Michael Ange*, *Dandie Dinmont*, *Belle Lilloise*, &c. Strange to say, the efforts of the Continental florists appeared to fall away with the production of this batch, for, with the exception of *Octavie Demay* and *Nemi Demay*, none others were introduced from France or Belgium in 1861. In the meantime the home florists had taken the fancy Pansy in hand, and from that time until this new fancy Pansies have appeared annually in great quantities.

I remember that when these fancy Pansies (Belgian Pansies they were then termed) were first introduced, the question arose, "Will the florists recognise them?" They did then, and do now, completely set at defiance all the recognised rules, written and unwritten, with regard to colouring; one could not determine grounds, blotches, margins, &c., as they could in the case of the show Pansies; their diversity of pleasing colours, their eccentricity of marking, their richness and warmth of hue could not be regulated by laws; but they became very popular, and remain so until this day. They possess qualities that commend them to public notice; they are generally vigorous growers, and produce a profusion of fine flowers. They will survive under conditions that seem to destroy the less robust show Pansies, and therefore they can be grown where the latter cannot be cultivated. I find that the

FANCY PANSIES that were planted out in October stood better through the winter than did the show varieties. I attributed this to their more robust habit of growth. But all the perils of the winter were as nothing to the perils of the biting frosty March winds. The second week in March, 1883, will be remembered as a kind of black time in the annals of floriculture, when searching, keen, east winds, made sharp by the hard frosts which accompanied them, killed many a favourite plant, and among them Pansies. They created not a few vacancies in my Pansy beds, which were in due course filled up from the necessary reserve of plants, and now I can gather beautiful flowers. I have watered, manured, top-dressed, and finally covered with Cocoa fibre, and I hope the plants will continue to flower all the summer. As to a

SELECTION OF THE BEST VARIETIES, I find the following to be very fine. New of 1883: *Bella Black*, finely shaded rosy crimson and yellow, extra fine; *Hon. G. R. Vernon*, dark bronzy crimson, edged with yellow and shaded with purple, very fine; *Mrs. J. E. Ward*, light lemon-yellow, with dark maroon blotch; and *Ruby*, upper petals rosy red, edged yellow, lower petals blotched with dark crimson, perfect form and very distinct. New of 1882: *B. K. Bliss*, dark maroon, shaded with light crimson; *Miss Bliss*, sub-bronzy red and yellow, edged with rose and white; *Miss Tofts*, dark mulberry, edged with yellow and rosy purple, distinct and fine; *Mrs. Paterson*, deep maroon, edged with yellow and purple, extra fine form; and *Mr. Kirkham*, pure white, with very large purple blotch, very fine. A general list furnishes the following as well deserving attention: *Archie Bowie*, lemon-yellow, fine deep blotch, very fine; *Catherine Agnes*, rosy purple and white; *Countess of Home*, yellow and bronze; *Darius*, large maroon blotch, upper petals margined with purple, large and fine; *Edward Caird*, rich dark ruby mulberry, shaded, extra fine; *F. W. Leland*, violet, veined with crimson on the under petals, upper petals dense violet margined with pale primrose, very distinct; *George Wood*, very rich light crimson, with dark blotches; *Hon. Mr. Bateson*, light sulphur, veined with rosy red and edged with white, large purple blotch; *John B. Downie*, rich light ruby crimson; *John Currie*, rich bronzy crimson, edged with yellow; *Lady Clerk*, white, large bluish purple blotch; *Lady Falmouth*, lemon-yellow and bronze, said to be the finest fancy Pansy yet sent out; *Miss Mackmicking*, creamy white, very fine; *Miss Minnie Methven*, rosy crimson, light purple blotch; *Mrs. Crawley*, dark rosy purple, with margin of pure white; *Mrs. E. H. Wood*, deep orange, edged with rosy purple, very fine; *Mrs. L. T. Fleming*, lilac, the upper petals laced with white; *Mrs. Wolfe Murray*, yellow and crimson, beautifully shaded; *Perfection*, dark mulberry, edged with white; *P. W. Tangrieve*, rose, edged with white; *R. K. Mitchell*, dark rosy crimson, extra fine form; *Robert Laird*, yellow and bright bronze-purple, extra fine; *Thomas Grainger*, very rich crimson, with black blotches, extra fine; *William Dalgetty*, maroon and purple, edged with yellow; and *William Melville*, back petals rosy purple, fine dark blotch, edged all round with yellow.

It is not too late to get a few plants for this season, but if they can be had in pots so much the better. If anyone has a hard, harsh piece of ground, a dressing of road grit and Cocoa fibre will greatly improve it and make it fit for Pansies. In planting, let some fine soil from the potting bench be put about the roots and a little Cocoa fibre. The roots work into this readily; they appear to derive nourishment from it, and it keeps them cool. Some care will be required to get a newly planted bed established, and mulchings and water will be necessary. A good position for a bed is one that allows of the plants having the benefit of the morning sun, and shade from neighbouring trees or buildings after the sun is at the meridian. Nor is it too late to sow a little seed, but it should be done without further loss of time. It will soon germinate, and if the young plants be carefully pricked out and grown on into size, they will make strong plants by August, and be very

gay during September and the autumn months. The Pansy is a true old-fashioned English flower, and it should find a place and be carefully looked after in every English garden.—R. D., in *Field*.

NEW GAILLARDIA.

LAST year M. Lorenz, of Erfurt, sent us specimens of his new double Gaillardia *Lorenziana*, and now we have another much in the same way, introduced by M.M. Vilmorin-Andrieux & Co., Paris. This is named *Aurora Borealis*, and, like *Lorenziana*, is a variety of the very variable *G. picta*, a half hardy annual. As may be seen by the accompanying

Flowers of Gaillardia picta Lorenziana.

woodcut, the new *Aurora Borealis* has its flower heads semi-double, whereas M. Lorenz's variety has blooms quite double. Both have bright yellow and red in the flowers, colours that make them so attractive as border plants. They are, moreover, very useful in a cut state, as the blooms last long in water. It is rather too late to sow seeds now, but if sown in September and the seedlings are kept over the winter in frames and planted out about the latter end of next April in the shape of vigorous young plants they would make a fine display the following summer. They are also amenable to pot culture, and if care is taken to induce them to form dwarf sturdy plants they would be valuable for conservatory decoration in spring and summer. For this purpose the seedlings raised in autumn should be grown on and repeatedly shifted into larger pots till spring.

GARDEN DAISIES AND THEIR TREATMENT.

ANYONE interested in Daisies and having a little spare time and space may easily raise a few seedlings. Half the number raised may possibly produce single flowers, but the other half will in most cases consist of double kinds of good form. The colours may vary from pure white to deep crimson, intermediate hues being for the most part delicate shades of pink. As the seed is small it is best to sow it either in pans or boxes. Early spring is the proper time to sow it, as then the plants will flower early in the summer; but it is not too late even now to sow the seed, and flower the plants in the early autumn months. An amateur with whom I am acquainted derives a good deal of pleasure from raising seedling Daisies. He sows his seed in pans in March, and places them in his greenhouse; when the young plants are large enough to handle, he transplants a portion of them singly into 4-inch pots, and flowers them in a cold frame; the remainder he plants in the open air after they have been well hardened. In my own practice I have dealt with them in much the same way. I, however, like the seed to be sown early in spring, as then the plants get strong enough early in summer to produce plenty of flowers. If sown early in March, and

the plants are grown in a greenhouse or cold pit, they will be large enough to plant out in the end of May. We select a shady border for them, make the soil fine and fairly rich, and plant 6 inches apart each way. They incur no further trouble, except to keep them free from weeds, until they commence to flower. Those which produce single flowers are thrown away, those only with double flowers being saved. On more than one occasion we have had charming beds of Daisies the following spring, and where mixed colours are not objected to it is the easiest way known to me of securing a healthy and thriving stock of plants simply because seedling plants are more vigorous than those raised from offsets.

In the management of Daisies for spring bedding where distinct colours are required, we are more tried than with any other plant we use for that purpose, and the reds give more trouble than the whites, but both seem to object to being removed more than once a year. When used in the flower garden for spring bedding they have to be taken up at the end of May to make room for the summer bedders, and it is to this second removal to which they seem to have a decided objection. Although we lift them carefully and plant them in a shady border, and supply them liberally with water in dry weather they dwindle away and die, or rather I should say a good portion of them refuses to grow. This is not the case when the plants are moved only once. If planted in February or March and allowed to remain undisturbed all the summer they do not die away in hot dry weather nearly so much as those which have been recently removed. We do not, however, care much if we can only keep alive half our stock until the middle of August, as by that time the summer heat begins to decline, the nights get cooler, and there are frequently heavy dews, which just suit Daisies, and they commence to make new growth; then is the time to set about getting up a stock. If the old stools are taken up and divided, every piece that has roots will make a plant. A position in the open should be selected for them, and the soil should be rather rich, as they do not object to a bit of manure. If the pieces in question are planted firmly, they will make sturdy plants by the time they are wanted for the positions in which they are to flower. The number and quality of the blooms will be more satisfactory if the planting is done by the middle of October than if planted later. J. C. C.

SELF-COLOURED DAFFODILS.

I AGREE with Mr. Brockbank as to the interesting Daffodil campaign, but I deny that he or anyone else has yet sent me a Daffodil in which the perianth segments and crown were of exactly the same shade of yellow. *N. obvallaris*, *N. maximus*, and *N. spurius* all contain at least two or three shades of yellow apart altogether from the light and shade effects upon the flower. The suggestion contained in the following paragraph, quoted from Mr. Brockbank's "final words" (p. 443) is neither just nor generous. Mr. Brockbank writes: "I think that if a stakeholder had had the custody of Mr. Burbidge's kettle, it would have now figured in my museum," but he forgets that there is a bare possibility of the "stakeholder" having had an eye sensitive to colour effects. I still maintain that there is no such thing as a real self-yellow Daffodil, and in quoting authorities in support of his views, Mr. Brockbank is simply begging the question. Even Mr. Wolley Dod does not believe in *N. obvallaris* being a true self, for in *THE GARDEN* (p. 443) his evidence is against Mr. Brockbank's opinion. He there says, "I think *maximus* is the most self," and yet even there he is too cautious to assert that *N. maximus* is really of one shade of yellow throughout. When Mr. Brockbank suggested *N. obvallaris* as a true self Daffodil, Mr. Barr wrote to me that the kettle was quite safe in my own keeping, and I shall yet prove that *N. obvallaris* naturally grown has two or three shades of yellow in the flower, to say nothing of the greenish shade of the tube. Even Mr. Brockbank himself had his doubts, or he would not have tried to limit my view of the

bloom he sent me to the hinder part of the flower only. I know of nothing so ingenious as this trying to see the colour of a flower from behind, and I shall reserve to myself the mode of examination, for if a flower be really self-coloured, *i.e.*, all of one colour, no way of looking at it or of testing its hue will make anything else of it than what it really is. No amount of argument can alter the real facts of the case, and Mr. Brockbank has neither shown nor proved that *N. obvallaris* is really self-coloured. Once for all, I deny that it is so.—F. W. B.

—A self-coloured Daffodil has not yet been introduced; the copper kettle may therefore remain for the present on Mr. Burbidge's hob. I have a better claim to the kettle than Mr. Brockbank, as one of Mr. Nelson's seedlings of *nanus* is as near as possible unicolor, but it will not stand the searching test which Mr. Burbidge applies to it. I fear the desire to have the best of the argument has a mischievous effect on Mr. Brockbank's mind, as I distinctly told him that the Tenby Daffodil was not self-coloured, though his specimen, which I looked upon as in the sere and yellow leaf, was nearer a self than a flower in good condition would have been.—F. BARR.

Lewisia rediviva.—It is somewhat remarkable how little notice this extremely lovely alpine seems to receive in the gardening papers. A plant for which I gave a shilling is now producing four large flowers on my rockery, and appears to flourish without especial care. There seems to be some discrepancy in the cultural directions for this plant, one recommending dry rubbish and grit, while the other advises peat and moisture. I am inclined to think the latter the more likely to lead to success.—J. C. L.

Ranunculus repens fl. pl.—The plant sent you by Mr. Wolley Dod (p. 502) came, I think, from my garden originally, and you will probably like a note upon its history. The original plant was found growing wild in the meadows about half a mile hence, as the crow flies, some five years ago. After we had grown it a year it suddenly disappeared, and on making inquiry I found it had gone to the rubbish heap as a weed. Luckily, it

Gaillardia picta var. *Aurora Borealis*, showing habit of growth. Detached flower about one-third natural size.

was recovered, and it now abounds with us and with the gardeners hereabout. It is a most remarkable plant, throwing out its runners in straight lines, sometimes 4 feet or 5 feet long, as straight as a ruler, and at every 6 inches it strikes root and sends up a lovely tuft of leaves and flowers.—W. BROCKBANK, *Brockhurst*.

TWO TRUE BLUES.

(LITHOSPERMUM PROSTRATUM AND MYOSOTIS RUPICOLA.)

THESE are just now in bloom in Miss Jekyll's garden at Munstead, and afford as fine an illustration as it is well possible to conceive of what the alpine flora can show in the way of colour. *L. prostratum*, forming circular masses over two knolls, is of the richest ultramarine or gentian blue, while a clump of *Myosotis rupicola* growing on the flat, and not far short of 2 feet in diameter, gives a blaze of rich turquoise, more exquisite in colour, I think, than any flower that looks the summer sun in the face. Can the coy *Erythrichium* really surpass this? A good plant of *L. prostratum* is probably within reach of most people who will give it room, though it prefers, I fancy, light soil and a little peat; but a display of *M. rupicola* such as is to be seen at Munstead is not, perhaps, to be achieved by gardeners who have to contend with heavy soils and the usual accompaniment of slugs. Let me take this opportunity of expressing my dissent from an opinion given in THE GARDEN (May 26, p. 463) as to

MERTENSIA PANICULATA. Miss Jekyll has a good specimen of this plant, but it is not, I think, superior to *M. sibirica*, while it is far inferior to *M. virginica*. The colour is not so good, nor is the truss so large nor the foliage so rich as in the latter, and the plant is more spindly in habit than either of the two. Except in cases where there is room for a collection, the plant is not worth growing side by side with *M. sibirica*, which flowers about the same time. *Apròpos* of Borage, a strong plant of

BORAGO LAXIFLORA is now in full flower on my rockery. If this had been given me by an old woman out of a cottage garden, instead of my paying a shilling for it at York, I think I should admit at once that it bears a strong affinity to a "Tush" plant. I am beginning to hope that "Johnson's Botanical Dictionary" may be right as to its longevity, and that it may prove to be a biennial; if so, *requiescat in pace*. J. C. L.

Miniature Ivies.—Growing on the rockwork in Mr. Stevens' garden are two small and curious kinds of Ivy named *Hedera conglomerata* and *subcordata*. The first-named has leaves not much larger than a shilling, and they are so densely packed on the stems as to overlap each other. *Subcordata* has larger leaves, the lobes of which are rounded off, the lowermost being the largest, which gives it a very distinct appearance. Both these Ivies are of slow growth, *conglomerata* especially so, and are only fitted for tree stumps, low walls, or for plants on rockwork. In the latter position they have a quite-at-home appearance, especially if so placed that they can ramble over boulder or large pieces of stone.—J. C., *Byfleet*.

Violas at Chiswick.—Presently there will be on a specially prepared border at Chiswick a capital display of Violas and bedding Pansies that will prove very interesting; as these are all young plants, they are not blooming so early as the old ones do in another part of the garden, a fact which serves to show that if a good and early display of these flowers is to be looked for, old plants, and not young ones, should be relied upon. Certainly of all the white kinds yet in bloom, *Grievei* is the finest and apparently the freest. The flowers are large, of good substance, bold, and abundantly produced; the colour is pure white, but marked by bluish lines round the eye. *Cannell's White* is another robust, free-blooming kind that is well worthy of cultivation; the flowers are large and almost free from stripes. There is an excellent yellow *Viola* called *Countess*, a bold flower of a good rich colour. This blooms freely, and for size and colour is one of the best now in bloom. At present there are no new or striking blue shades open, but some may presently appear worthy of notice. So far all the kinds are of a purplish or violet-blue, but of true blues there are few, if any. A seedling black kind from Aberdeen is very striking, but none of these very dark sorts have ever made good bedders. A very charming kind

in the Magpie style is *Viola Treatie maxima* Lord Beaconsfield. The bottom petals are of deep violet-blue, and the upper petals shade off to white. This is a very effective kind. Those who seek for good foliage effects in the spring should make a note of the golden *Lamium*, which is at Chiswick here and there in clumps very bright and showy.—A. D.

Gentiana verna.—I found this lovely little alpine growing somewhat plentifully in two places in Teesdale last week. The two spots where it was growing were about three miles apart, one on the banks of a small beck, the other on a wind-swept fell. In each case the plants would receive abundant moisture, the district being a rainy one. Amongst the numerous other wild flowers in bloom in the dale, *Primula farinosa*, *Trollius europæus*, *Caltha palustris*, and (in drier places) *Orchis mascula* and *Saxifraga granulata* were very abundant.—T. M.

Hairbell and Bluebell.—The Hairbell (so called because of its bell-shaped flowers being suspended on hair-like stems) is far removed from the Bluebell, belonging, in fact, to a different Natural Order. The Hairbell (*Campanula rotundifolia*) is generally blue, though last summer I found the white variety growing near to the common one on a sandbank. It flowers from July to September, grows mostly on dry banks or heaths, and is one of the most graceful of our wild flowers, the bells, hung on a loose raceme, swinging to and fro with every breath of wind. The Bluebell (*Agrostis nutans*), or wild Hyacinth, is the Bluebell of Scotland, and belongs to the Natural Order Liliaceæ. Its growth mostly in woods or shady places, blooms from April to June, and bears its flowers rather stiffly on a thick succulent stem—in short, like a Hyacinth, excepting that the raceme is one-sided. The English Bluebell (*Hyacinthus non-scriptus*) is also a Hyacinth, and is found mostly in woods or thickets. I understand there is a white variety occasionally met with, but I have never seen it.—A. H.

Bedding Pansies.—I was much struck the other day by seeing in bloom, both at Maiden Erlegh and The Wilderness, Reading, masses of that fine white Pansy, Mrs. Cannell. I do not know who sent it out, but it is a fine free-blooming kind, flowers large, pure white, and having a large dense bluish-black blotch. I have been seeking for a striking white market Pansy, and in Mrs. Cannell I think I have found it, for if offered at a cheap rate tens of thousands might be sold with ease. Great Eastern is an old kind, and where it does well is a telling variety. It certainly is so at The Wilderness, but still not so effective as Mrs. Cannell. A truly fine orange-yellow kind is New Guinea. This is, I think, one of Mr. Hooper's kinds. At all events, it is a grand sort at The Wilderness, the flowers being large and stout, with a deeply coloured blotch; New Guinea promises to make a splendid market variety also. In both the above-named gardens *Viola Mulberry* blooms abundantly, and is most effective; and *Magnifica*, one of the violet-purple section, is a charming kind.—A. D.

SHORT NOTES.—FLOWER.

Solomon's Seal in London.—It is pleasant to see the way in which this plant does in the parks, where it spreads itself here and there so gracefully, suggesting how easily all the bare borders might be covered with good plants—plants well chosen and well placed!

Gold-laced Polyanthus (A. G.).—Very good blooms indeed, and show admirably what fine sorts may be obtained from a seed bed. As you observe, they are valuable border flowers at this season, and not half grown enough.

Houseleeks.—Why does Mr. Ruskin call the *Sedum* a Houseleek (!) when he proposes to alter the generic name to *Stella*? "*Proserpina*" is very clever, as all his books are, but I am afraid the system which it attacks is beyond cure, owing to the unmanageable dimensions which it has attained at the hands of its fosterers, who must be very thick-skinned indeed if they do not feel that the cumbersome mass of synonyms, multiplied genera, &c., which they have so lovingly and industriously piled up is now, Frankenstein-like, recoiling upon their own heads.—W. M.

ORCHIDS.

ORCHIDS AT UPPER HOLLOWAY.

AT any season a visit to Mr. B. S. Williams' Nursery, Upper Holloway, is well repaid, and particularly now when, like the other great London nurseries, it is gay with Orchid blooms. Every one of the numerous houses in this establishment now contains a marvellous amount of bloom. The first house we enter is a span-roofed one, occupied chiefly by Cattleyas, *Lælias*, and others, requiring an intermediate temperature. There is here a very fine display of bloom effected chiefly by the favourite old *Cattleya Mossiæ*, still the finest species of this genus in cultivation, particularly having regard to the wealth of varieties belonging to it, a large number of which may be seen in bloom in this collection, not represented by small specimens, but by huge masses, carrying in some cases as many as a score of blossoms. Large specimen plants are a prominent feature in Mr. Williams' collection, and well may he pride himself in his superb specimen Cattleyas, *Lælias*, *Vandas*, and the like; but it is only when seen arranged as they now are with gorgeous bloom that a correct estimate can be formed of the size and superiority of the plants. Among the numerous forms of Mrs. Moss' *Cattleya* here we singled out a few that struck us as being uncommonly fine. The first we noted was named *Rothschildiana*, a truly superb form, possessing delicate shades and tints which mark it as distinct from any other variety. It has large finely formed flowers, which are, moreover, very richly coloured. The same remarks apply to other named varieties, such as *grandiflora*, *splendens*, *superba*, *speciosissima*, *majestica*, and *grandis*. One named *aurantiaca*, however, may be recognised at a glance on account of the excessive amount of golden yellow which adorns its ample labellum. It is aptly named, for all the forms have more or less a suffusion of yellow in the lip, but none so marked as this one. *C. Mendeli*, as may be imagined, is in the height of its beauty, and here again there are several indescribable varieties, some very much superior to others, but all beautiful. One named *Alexandræ* possesses about the most delicate touch of colouring we have seen. There is a decided tinge of rosy pink about it, but this in such a subtle gradation that in some lights the flower seems almost white. Its labellum is adorned with a dainty touch of deep amaranth, which shows off more strongly the delicacy of the other tones of colouring.

LÆLIA PURPURATA is likewise in full beauty, and is represented by such superb varieties as the white variety (*alba*), with snow-white petals, and Williams', a kind remarkable for its very large and richly coloured labellum and mauve-tinted sepals and petals. These *Lælias* are a sight in themselves, being for the most part huge exhibition plants carrying several spikes of flowers. There is a multitude of other species in bloom in this house which, taken altogether, make a charming display. We cannot leave it, however, without commenting upon the uncommonly fine specimens of *Cypripedium superbiens*, one of the handsomest of all the Lady's Slippers. Here are plants carrying a dozen or more flowers in various stages of expansion, which is a much more interesting phase than seeing a lithe flowers fully open and staring at one. We made note of an extraordinary fine form of this *Cypripedium*, known here as the Prince Demidoff variety. It has larger flowers than the typical with broader petals more densely spotted, and the colour altogether of the flower is richer.

THE VANDA HOUSE comes next, and, like the other, is gay with bloom. The specimen *Vanda tricolor* and *suavis*, of gigantic proportions, are throwing out their large racemes and giving off a delicious aromatic perfume in the house. Intermingled with these, and producing an extremely pretty effect, are the three evergreen *Calanthes*, viz., *veratrifolia*, *Masuca*, and *Domini*, the two first the parents of the latter, which is exactly intermediate between the two. These all have tall graceful flower-spikes terminated by a dense cluster of flowers, and these spikes springing

from the broad handsome foliage associate charmingly with the Vandas, creating an unusual and pretty effect. Some choice varieties of *V. tricolor* may now be seen in bloom, but the bloom of the bulk of the collections is on the wane, and the bright sunshine accelerates the fading considerably. Among other East Indian Orchids in the house may be seen the rare and beautiful *Aerides Veitchi* and *A. Lobbi*, both with long wreath-like spikes of rosy purple flowers. Then again there is the larger growing *A. crispum* and its more highly coloured variety, *Lindleyanum*; and among *Saccolabiums* are the Indian red-coloured *S. curvifolium*, represented by good specimens, *S. guttatum* and several others; in short, the collection teems with choice and beautiful species and varieties in bloom.

THE COOL HOUSE contains a wealth of bloom chiefly effected by the *Odontoglossums*, among which the lovely *O. Alexandræ* reigns supreme, and rarely can it be seen represented in such choice varieties as here at the present time. All the plants bear such large, finely-shaped flowers, that we wondered were Mr. Williams could have put all the stately flowered varieties which usually predominate in importations. His collector has evidently hit upon the right locality for securing the best varieties, for these have been more numerous here than inferior ones for a long time past. There is ample colour to brighten up the *Odontoglossums* by the *Masdevallias*, which are developing thickets of spikes, *Harryana*, *Veitchi*, and *Lindeni* being the most prominent in the display. Those who like to see rare Orchids in bloom can have the pleasure of *Odontoglossum brevifolium*, which is an extremely handsome plant in the way of *O. coronarium*; it has prostrate growth, and bears from the new growth a huge spike of blossoms, each about an inch across, of a rich, brownish yellow, with markings of a golden hue. It is grown in the cool house in a long, shallow box to accommodate its running stems.

CATTLEYA SKINNERI.

THE vigorous constitution and free flowering nature of this *Cattleya* recommend it to all Orchid lovers. When grown into large specimens it is one of the most effective flowering plants with which I am acquainted. The individual blooms may not impress one with their beauty so much as is the case with some of its congeners, but when they are counted by the score or hundred they form a very striking mass of colour. Some of the largest plants I ever saw were grown in baskets in pure *Sphagnum* and charcoal. The roots were never disturbed in shifting, as when the necessity for such arrived, the old basket was dropped into the new one, and fresh Moss packed in between them, so that not the slightest check was experienced. I forget the exact dimensions of the plants, but there were two of them, and on one I counted 370 expanded blooms. I should like to know if there is any record of such large specimens as these having been grown in this country. It may easily be imagined that such huge specimens were very effective; it was, indeed, quite common to hear inexperienced visitors exclaim, "What beautiful *Rhododendrons*!" and Mr. Harry Veitch, who saw them, was much impressed by their uncommon excellence, declaring them to be far beyond the finest examples of Orchid culture he had ever met with. Now that Orchid culture has been brought to such a high degree of excellence, it should not be difficult to form such large specimens; and as this *Cattleya* is cheap and its requirements easily met, it should be grown wherever a high standard of excellence in floral decorations is aimed at. Orchids are not commonly classed amongst so-called decorative plants, the beauty of the individual blooms rather than their effectiveness as a whole being hitherto the chief inducement to their culture, but the time will probably come when some of the most easily grown and showy species will be valued chiefly for their utility for conservatory or room decoration. Seeing that they are as easily managed and not more expensive to keep than so many things

now employed for that purpose, there can be no reason why they should not be largely grown for general decorative purposes. Expense of purchase is no great bar, as such fine showy kinds as *Cattleya Skinneri*, *Mendeli*, *Trianae*, *Lælia harpophylla*, and others can be bought at from 2s. 6d. each, a no greater price than that demanded for a good *Erica* or choice hard-wooded plant. When Orchid growing enters upon this phase, as I think it will ere long, these charming and curious plants will become, in the true sense of the word, popular.

J. CORNHILL.

VARIETIES OF MASDEVALLIA HARRYANA.

A SPLENDID assortment of this Orchid has been sent to us by Mr. Newsham, gardener to Mr. Yates, Higher Feniscowles, Blackburn. We have never before had such a collection of such superb flowers before us, which represent, we imagine, the cream of the numerous forms of *M. Harryana* now in gardens. The most remarkable of those sent are the following: The Bull's Blood variety has blossoms $2\frac{3}{4}$ inches across, and of a resplendent magenta, with conspicuous streaks of a deeper colour. *Yatesi* is remarkable for the unusual length of the flower, being $2\frac{3}{4}$ inches from the centre of the tube to the tip of the attenuated sepals, while the breadth is but $1\frac{1}{2}$ inches. The colouring of this variety surpasses that of any other that has come under our notice, being glowing crimson-scarlet with a satiny surface. *Chelsoni* has flowers $2\frac{1}{2}$ inches broad, and is similar to the Bull's variety, but there is a decided flushing of purple in the flowers. An unnamed imported variety is somewhat similar to that known about London as *lilacina*, but the flowers are larger, being $2\frac{1}{2}$ inches across and the same in length. The colour is a brilliant rosy purple, pencilled with a deeper tint, the eye being pure white, and thus producing a beautiful contrast. What is sent as *Harryana* is one of the finest; the flower is as large as that of the last variety and of a carmine-magenta overlaid with a satiny lustre. In addition to those sent, Mr. Newsham says he has the following beautifully in bloom, viz.: *M. Harryana magnifica*, *atro-purpurea*, *discolor*, the *Drumlanrig* variety (almost as fine as *Yatesi*), *Walker's* variety, *sanguinea*, *Backhouse's fulgens*, *M. Lindeni superba*, *M. ignea rubescens*, and a small plant of *M. rosea* with over a dozen flowers on it. Judging by the flowers sent us and from what we hear, Higher Feniscowles must contain a wonderfully rich collection of Orchids.

HARDY ORCHIDS.

I SEND you flowers of the true Man Orchis (*Aceras anthropophora*) which, as you will see, are not entirely devoid of interest; they are, indeed, showy and attractive when grown in clumps consisting of three or four plants. Intermixed with these are two or three of a more attractive form, having the outer portions of the man distinctly tipped with pink, but in these the flowers are not arranged in such a dense spike as in those sent. This Orchid has flowered well with us on sunny slopes in a mixture of loam and lime rubbish. Another attractive species in flower at present is *O. undulatifolia*, which is, in formation, almost a counterpart of the Man Orchis, but the flowers are light pink in colour, streaked and spotted with white. This is one of the most ornamental of hardy Orchids, and easily grown in rather damp peaty ground. The stemless Lady's Slipper (*Cypripedium acaule*) is now in full flower, as is also the rare and curious *C. parviflorum*, the fragrant flowers of which are bright yellow, with sepals and petals of brownish purple. The flower on *C. acaule* is a rich rose in colour streaked with white, and issues from a pair of large ovate hirsute leaves. Other hardy Orchids in bloom at present are two *Serapias*, *S. cordigera* and *S. neglecta*, with large, attractive, blood-red flowers and an exceedingly long lip; the Butterfly Orchis (*O. papilionacea*), with bright crimson blossoms; and *O. Stabiana*, one of the most beautiful of the Italian Orchids, with large leaves and

large, flat, attractive flowers. *Habenaria montana*, received from the Continent, though outwardly resembling our *H. bifolia*, has a much smaller and more showy flower. What a sweet little plant is our native *H. albida*! It is now in full flower, but rather a difficult subject to deal with, involving a good deal of trouble to get it thoroughly established. The Musk Orchis (*Herminium Monorchis*) is just the reverse, and increases rapidly here in fine calcareous loam.

A. D. WEBSTER.
Llandegai, Bangor.

THE BRENTHAM PARK ORCHIDS

THIS celebrated collection, on account of the ill-health of its owner, Mr. R. Smith, was disposed of at Stevens's Rooms, Covent Garden, on May 30 and 31 and June 1. Some 790 lots were included in the sale, the whole amount realised being £2100. As usual, the choicest species and varieties fetched high prices, and there was a brisk bidding for them. Among these we noted the following: *Cattleya exoniensis*, a grand specimen and very fine variety, with fifteen strong bulbs and leaves, said to be the finest plant in the country of this rare hybrid *Cattleya*, 110 guineas; *C. Trianae alba*, a perfect specimen of this grand variety, with thirty strong bulbs with leaves and eleven breaks, one of the finest plants in the collection, 75 guineas; *Lælia anceps Dawsoni*, a fine specimen with ten strong bulbs and six breaks, 45 guineas; *L. anceps alba*, true, the finest plant of this rare variety in the country, twenty-four bulbs and six breaks, 41 guineas; *Cœlogyne Massangeana*, a perfect specimen with sixteen bulbs and eight breaks, flowers twice each year, the plant referred to in Williams' Orchid Album, 40 guineas; *Cattleya Skinneri alba*, true, from Mr. Turner's collection, eight strong bulbs and two leads, very rare, 38 guineas; *Lælia grandis*, very rare, a grand plant with eighteen bulbs and two breaks, 31 guineas; *Cattleya labiata*, true, autumn-flowering variety, splendid plant, twelve bulbs and three strong leads, 30 guineas; another plant with eight bulbs and leaves and three breaks, 29 guineas; *Oncidium ornithorhynchum album*, a specimen with thirteen very large bulbs and two strong breaks, 28 guineas; *Lælia elegans alba*, a strong plant of nine bulbs of this rare variety, 24 guineas; *Aerides Schröderi*, a fine plant with twenty-three leaves and flower-spike, very rare, 21 guineas; *Cattleya Trianae alba*, a fine plant with thirty-three bulbs and eight breaks, 20 guineas; *Odontoglossum blandum*, finest variety, had eight spikes last year with fourteen bulbs, 20 guineas; *Cattleya labiata Warneri*, very fine variety, and a handsome specimen with two flower sheaths, 18 guineas; *Cattleya labiata*, $15\frac{1}{2}$ guineas; *Odontoglossum coronarium*, exceedingly fine specimen with thirteen bulbs and five strong growths, 14 guineas; *Cattleya Skinneri*, fine specimen, thirty-six strong bulbs, six leads, the darkest variety, from the Burton Constable collection, had fifty flowers on this year, 13 guineas; *Lælia Wolstenholmie*, ten bulbs and two leads, very rare, $10\frac{1}{2}$ guineas; *Vanda tricolor formosa*, fine specimen, 3 feet high, and four good plants, 10 guineas; *Aerides Dayanum superbum*, specimen, $2\frac{1}{2}$ feet high, with five good plants, about 18 inches high, $10\frac{1}{2}$ guineas; *Odontoglossum nevadense*, a rare and distinct species, 10 guineas.

Odontoglossum citrosimum marginatum would be an appropriate name for a variety sent to us by Mr. Voss from his garden at De Montfort House, Streatham. We are inclined to pronounce it the loveliest variety of *O. citrosimum* we have yet met with, not only as regards the colour of the flowers, which is exquisite, but the large size and beautiful form of the flowers. The sepals and petals are rounded and so broad as to overlap, and have prettily crisped edges. They are of waxy whiteness, delicately flushed with rosy pink, and still more delicately spotted with a tint of a lighter shade. The lip is its chief feature of beauty; it is $1\frac{1}{2}$ inches across, semi-circular, and crisped at the margin. The colour is a pleasing rose-purple bordered with a distinct edging of plum-purple, which gives the flower such a different

appearance from any other form; hence we suggest the name *margioatum*. The perfume, too, is delightful, reminding one of a mixture of honey and Primroses. This is certainly a rare and lovely variety.

Phalænopsis Sanderiana superba.

A spike of an extraordinarily fine variety of this species was exhibited at Stevens's Rooms, Covent Garden, on Thursday last, by Mr. F. Sander, cut from a plant grown by Mr. Hill, gardener to Sir Nathaniel Rothschild, Tring Park. It is by far the deepest tinted variety we have seen, being several shades darker than those shown at South Kensington a short time since by Sir Trevor Lawrence and Mr. Lee. The long slender spike bore seven flowers, each about 4 inches across; they were of fine form, that is, the sepals and petals were so broad as to almost overlap. The flowers much resemble in structural characters those of *P. amabilis*; indeed, it may be best described as a pink *amabilis*, but the foliage is intermediate between that species and *P. Schilleriana*. The colour of this fine variety is a deep rose, reminding one of a deeply tinted *Odontoglossum vexillarium*. The darker coloured pencillings, which form a network on the sepals and petals, add much to their beauty. This is undoubtedly the queen of the genus to which it belongs, at least so far as we have any knowledge of cultivated kinds. A fine healthy importation of it was sold on Thursday last by the importer, Mr. F. Sander.

Lælia purpurata.—A glorious spike of this grand Orchid has been sent to us by Dr. Paterson. It carries five very large flowers, the lips of which measure nearly 2 inches across. The colour of the petals and sepals is faint mauve-purple; that of the lip a rich port wine shade, with numerous veins of a lighter hue traversing the whole. This spike was cut from a large specimen, which must indeed have been a sight worth going a long distance to see.

Orchid monstrosities seem unusually plentiful this year, judging by the numbers that are brought under our notice. Mr. Moss sends us from his collection at Weston Grove, near Southampton, a twin-flowered *Dendrobium suavisimum*. The fusion extends to the stalk, and there is not much malformation in either of the flowers. It is quite an unusual occurrence. Mr. Moss also sends a malformed flower of *Cattleya amethystoglossa*, the deformity being the absence of the labellum, a loss which by no means improves the look of the bloom.

Oncidium phymatocillum.—A fine spike of this Orchid has been sent to us by Mr. Pollett, Fernside, Bickley, where it is flowered successfully every season, notwithstanding its reputation for being difficult to bloom. Perhaps Mr. Wilson, the gardener there, could give us the benefit of his experience with regard to the culture of this *Oncid.* It is not what would be called a showy species, but the flowers, it may be remarked, are very curious in structure, and so plentifully produced on tall branching spikes as to give one the idea of a swarm of insects.

Saccolabium curvifolium.—Another example of Mr. Denny's skilful culture is a remarkably fine spike of this East Indian Orchid which measures about 9 inches long. For two-thirds of its length it is thickly covered with flowers, in all numbering thirty-four on the spike. Such a fine wreath of this Orchid is really beautiful, the colour, a bright orange-red, being so uncommon even among the Orchids. From the Down House collection Sir William Marriott also sends a spike of *Lælia majalis*, one of the loveliest of Mexican flowers, but among the most difficult to flower freely in this country.

Dendrobium thyrsiflorum.—I saw in THE GARDEN (p. 458) mention made of a *Dendrobium thyrsiflorum* bearing six large flower-spikes. I have two good plants of this *Dendrob.* in 8-inch pots, one with ten, the other with eleven large drooping spikes, averaging forty flowers to a spike. On some spikes there are fifty flowers.—J. TURK, *Sewardstone Lodge, Chingford.*

Odontoglossum citrosimum roseum.—An unusually deeply tinted form of this Orchid comes to us from Sir W. Marriott's garden. The labellum is of a deep rose-pink; the sepals are also flushed with pink, and the petals are white and copiously spotted with the same colour. In strong contrast to these delicate tints is the bright orange crest of the lip, which is densely spotted with brown. The long, pendulous spike sent is a beautiful object.

Odontoglossum vexillarium at Birdhill, Clonmel.—An enthusiastic gardening friend once told me he once seemed strongly inclined to lift his hat to a well-grown specimen of *Cattleya Mossiae*, seeing it for the first time. There are several really fine specimens of this, probably the most beautiful of all the *Odontogloss.* at present gorgeously in bloom in the vestibule of the stove with Mr. Gough, at Birdhill, that would excite a similar feeling. They were procured through Mr. J. C. Stevens as small plants only two years since. On one plant there were five spikes, on which I counted thirty blooms, with probably a few yet to come. They were grown in a cool house, frost merely excluded, and put here for the blooming period. A number of other Orchids here were also fine.—W. J. M., *Clonmel.*

Chysis bracteescens.—We had no idea that this was such a beautiful Orchid until Mr. Denny sent us an enormous spike the other day from Sir William Marriott's garden. There are seven flowers on the spike, each of which measures fully 4 inches across. The pure white petals are very thick and wax-like, and so beautiful in form as if chiselled out of some such solid substance as marble. The only colour are the stainings of citron-yellow on the edges and crests of the lips. There is not a trace of odour. Seen thus it is a lovely and noble Orchid. Another white flowered Orchid from the Down House collection is *Vanda Denisoniana*, which, though so rare, cannot compare for purity of colour or beauty of form with the *Chysis bracteescens*; in fact, this white *Vanda* is, we consider, an overrated plant, being, as a rule, an indifferent grower, and rarely seen represented as a presentable specimen.

Cattleya Mossiae.—Of this Orchid Dr. Paterson, of Fernfield, Bridge of Allan, sends us a magnificent spike representing one of the finest varieties we have seen. Its blossoms are not so remarkable for large size as for their peculiar and distinct colour. The sepals and petals are a delicate blush-pink, and the broad labellum is half citron-yellow and half bright amaranth of various shades. An exquisite frilling of white adorns the edge of the lip, and sets off the other colours to advantage. Dr. Paterson says "it was cut from a plant bearing five spikes with fifteen flowers; this plant I got from the late Provost Russel, of Falkirk, fifteen years ago." Another exceptionally fine variety of *Cattleya Mossiae* has been sent to us by Mr. Brinsley Marlay, Belvedere House, Mullingar. In this case the remarkable feature is the very large size of the bloom, which is moreover one of the deepest tinted, the labellum especially being richly coloured. These two varieties admirably show the wealth of colour and form existing in this species.

Rhododendron ehow.—The annual display of *Rhododendrons* from Mr. John Waterer's nursery at Bagshot was opened during the past week at the Cadogan Place Gardens, Sloane Street, and will remain on view for some weeks. The present show is quite equal to any of its predecessors, and represents, as usual, all that is fine in the way of hardy *Rhododendrons*, for which the Bagshot Nurseries are so celebrated. Besides many new unnamed seedlings, there are fine bushes of such favourite varieties as *Kate Waterer*, *John Waterer*, *Duchess of Connaught*, *Princess Louise*, *Princess Christian*, *Earl of Harrington*, *Alarm*, *Robert Marlock*, and *Duchess of Bedford*. For the next three weeks or so there will be different varieties unfolding their blooms. As usual, the show is a brilliant one and the arrangements admirable.

QUESTIONS.

5001.—**Heuchera Richardsoni.**—Will some reader of THE GARDEN kindly tell me where this can be purchased?—S. W. C.

5002.—**Litter for Strawberries.**—Will some one say whether bad hay will do as a litter for Strawberries, as well as straw to keep the fruit clean?—E. C.

5003.—**Flageolet Beans.**—What kind of Beans are those called Flageolets? and can they be cultivated in England? They are preserved in France, and sold here in bottles.—C. R.

5004.—**Air roots on Vines.**—Will some correspondent kindly tell me the cause of what gardeners call air roots growing on Vines? and whether they are in any way injurious?—J. M. W.

5005.—**Woodlice.**—What will prevent sow bugs (woodlice) from eating the Peach blossom and fruit just setting? They come in large numbers at night out of holes in the wall. Will some one kindly give me a remedy?—STRATHPEY.

5006.—**Slag sand.**—Can any of your readers do me the favour to say where one could obtain this sand? It has, I see, been strongly recommended in THE GARDEN for keeping away slugs. No one about here seems to know anything about it.—C. F., *Mertwood.*

5007.—**Rose bug.**—Can any of your readers kindly inform me of an effective preventive against the ravages of the Rose bug? Though the blooms are examined night and morning daily, we have scarcely a decent Rose remaining, solely on account of this pest.—C. W.

5008.—**Violets in September.**—I shall feel obliged if any of your readers can inform me how Violets are obtained in September and October. Is the plant that produces them a distinct variety? or is this blooming effected by lifting and transplanting at some special season of the year? What soil do they grow best in?—E. M. S. B.

5009.—**Thrips on Cucumbers.**—What is the best thing to extirpate thrips in a Cucumber house heated with hot water? I am afraid it will be suggested that my gardener has fruited his plants a little too heavily, and I think he has; but, thrips having gained a lodgment, what I want to know is, how best to get rid of them.—SUBSCRIBER *Maldon.*

5010.—**Brunevigia Josephinae.**—I have a plant of this in a warm greenhouse. It did not flower last year. This winter the foliage has been much better than last year, but has died down again now. As I suppose it flowers without foliage in August, how had I better treat it now—water it fairly, or leave it dry, or how? Does it need to be very warm or cool?—J. P.

5011.—**Roses and Grapes.**—I am anxious to know the names of twelve of the best pot Roses for early forcing. Will some of your correspondents also kindly advise me to the best method of preserving Grapes in a vinery in wasps? Notwithstanding precautions on the part of our gardener, one crop of our Grapes was entirely destroyed by wasps last autumn.—E. W. G.

5012.—**Roses under glass.**—I have a span-roofed house in which Roses are planted in raised beds. They were forced, but with poor results, the growth being very weak. My idea is to gradually harden them off and ultimately remove the lights entirely, and try to encourage a strong summer's growth to force next year. Might I thin out the first weak growth to further this aim? Any hints on the subject would greatly oblige me.—AMATEUR.

5013.—**Potatoes on the same ground year after year.**—I shall be much obliged if some of your readers will kindly answer the following questions: 1. My gardener has planted in the same ground our own seed Potatoes from last year—*Magnum Bonums*, *Champions*, and one other sort. Last year our *Magnum Bonums* were pretty free from disease, but the *Champions* were diseased. I tell my gardener, unless all the authorities are wrong, that planting on the same ground year after year is a mistake; and his reply is, he knows a man who has planted the same seed in the same ground for twenty years and had no disease. I should mention that our seed was from a fresh place (in England) last year. Is this wise or the reverse?—F. B.

* * * Our readers will greatly oblige by replying so far as their knowledge and observation permit to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

KITCHEN GARDEN.

CABBAGES OF DIFFERENT COUNTRIES.

FEW vegetables are more economical than Cabbages, seeing that they can be eaten almost from the time when they leave the seed bed until they grow into a hard, close head, and they form a crop that can at any time be put upon any otherwise idle ground, and yield a good supply of green food. The modern cultivator expects to be able to cut good-hearted Cabbages from early spring until late in autumn in proper order and succession. Cabbages may be divided into four classes, the first, and most useful, being the cone-shaped garden varieties; second, the Savoy type; third, the rosette type used for bunching; and fourth, the Drumheads, so useful for cattle food. Drumheads have perhaps never been so fully appreciated as at the present time; they grow to an enormous size, solid, and flat on the top. Not only are they grown abundantly in the humid climate of England, but also extensively throughout the Continent of Europe and the States of America. In Germany the consumption of this variety is considerable. The large white Cabbage, called by them *Felderkrant*, is also a variety grown extensively there. It is cone-shaped, with a very sharp point, similar in form to the *Winningstadt*, but longer and broader at the base; the head is very solid, and without many leaves at the side. It is grown for *sauerkraut*. For this the head is cut into slices, as we do in pickling, putting it into layers with a little oil and salt, and subjecting it to great pressure, when it is left for fermentation. This is said to be antiscorbutic, and valuable in the case of long voyages.

The *Schweinfurth* is also a large-headed sort and very tender; so much so, that it cannot be transported far for market purposes, but for summer and autumn use it is very valuable. The large flat *Brunswick*, *Winningstadt*, and *Magdeburg* Cabbages are popular there, as are also *Yorks* and other English varieties.

To France we are indebted for some useful Cabbages. The variety called *Quintal* originated there; it is a large sort, the heads of which are quite flat on the top; it is one of the oldest in cultivation. The *Etampes* variety is considered to be the earliest grown of an Ox-heart shape. The *Bacalan*, *Cœur de Bœuf*, and *Saint Denis* are favourite Cabbages with the French, but some of their leafy and stalky varieties would not be allowed growing room in our English gardens.

Jersey has almost the exclusive growth of a Cow Cabbage peculiar to itself. It is a perennial, having a stem sometimes reaching a height of 12 feet, its leaves being plucked from the bottom, and used for cattle food. The stalks are sometimes made into walking sticks. It does not succeed in this country.

The Americans have made, as respects the cultivation of Cabbages, as indeed in everything else, some tremendous strides. Their *Mammoth* Cabbages often weigh 50 or 60 pounds each, and their solidity is something unknown to us. Cabbage growing with them is, however, attended with difficulties, of which we in England know little. Their winters are so severe that Cabbages for winter or spring use have to be stored away underground, or in cellars. When grown for seed they are allowed to head in the autumn, and then pulled and stored away in a dry place, to be replanted in spring. In the Southern States, a popular variety is that known as *Green Glazed*, a kind peculiarly valuable in excessively warm districts, from the fact that it withstands the attacks of caterpillars better than any other sort. It is rather coarse, loose-headed, and of a dark shining sea-green colour. Their *Marble Head Mammoth* is perhaps the largest variety of Cabbage in existence, the result of extremely high culture. *Henderson's Early Summer* is a good second early Drumhead, larger than *Jersey Wakefield*, and valuable from the unusually long time during which the head remains intact before bursting. *Early Winningstadt*, a large-sized Cabbage, broad at the base, and twisted up to the top, has been found to head well on land and

under circumstances most unfavourable to other Cabbages. *Fottler's Improved Brunswick* is a great favourite; it is a very large, flat-headed Cabbage with a short stem. The true type can always be identified by the revolte curl seen in the edge of the outside leaf of the head. *Early Wymen*, *Jersey Wakefield*, and *Flat Dutch* are also favourite American Cabbages. *Collards* or *Rosette Coleworts*, already referred to as a valuable type for bunching purposes, are also used by the Americans. As the name indicates, they do not heart, but the leaves close up towards the centre in the form of a rosette. Their robust and vigorous character ensures their appearance when other green food is perhaps not available.

Such hot climates as the Cape and East Indies are dependent chiefly upon Drumheads for their supplies, and they possess a favourite variety termed *Cape Drumhead*, a kind possessing considerable size. In England the quantity of Cabbage seed harvested annually is very considerable, supplying not only the demand at home, but much of the requirements of many other countries where this vegetable is grown. English Cabbages are generally regarded as very desirable. But seed-growing in England is not unattended with difficulties and risks. From the middle of July until the middle of August, according to sorts, is the proper time to transplant from the seed bed to the open field for the following year's harvest—too late to form a very solid head, and yet early enough to make strong and vigorous growth. The utmost difficulty is experienced at this dry time to catch the desired showers of rain necessary for the removed plants. If, too eager to take advantage of rain, the grower removes his plants early, they will head and probably rot in consequence during the winter. If continued drought should prevent their removal until late, a great quantity will probably not run to seed, and a short crop the following harvest is inevitable. The grower must also take care that when in bloom bees have no opportunity to cross the different sorts. Varieties with close heads, expanded leaves, or coloured veins must be kept long distances apart.

In growing Cabbages for table even, no little care must be exercised in order to produce a regular supply. Many are fastidious as to the sorts grown, and, knowing the distinctive peculiarities of such, are careful to sow and transplant at the proper period—perhaps even the precise day—in order that they may be able to "cut" at the proper time. *Early York* stands conspicuous among the earliest and best standard varieties, followed by *Large York*, a somewhat later and larger sort. These, when compared with the very solid varieties in demand, are not unlike in appearance the *Cos Lettuce*, but their hardness and ability to withstand severe weather make them very reliable. For a main crop the *Enfield Market* is an excellent type. It has a cone-shaped head, is very solid, and certain to head. Several of this class are in commerce, but no Cabbage has been more grown by market gardeners during these last thirty years than the *Enfield*. The *Winningstadt* is also distinct, and must eventually become as great a favourite with us as with the Americans.

The Savoy type is one of the most invaluable of the Cabbage tribe. The crumpled texture of the leaf gives it a distinctive character, and it is at once among the tenderest and sweetest flavoured of all Cabbages; for family use it is even superior to the cone-shaped or Drumhead varieties. *Little Pixie*, *Green Curled*, and *Globe* are equally useful sorts. The *Golden Globe* has a golden tint, which makes it attractive.

The *Rosette Collard*, or *Colewort*, from its hardness has become invaluable for bunching purposes during winter, and fills an important gap which the cone-shaped, solid-headed Cabbages cannot do. A peculiar anomaly has recently been introduced to our gardens called *Chou de Burghley*. It is neither a Cabbage nor a Broccoli, but partakes of the character of both. It forms a Cabbage head, and the interior column also bears very small Broccoli heads. It is said to have an exquisitely sweet and mild flavour. Thousand-

headed Cabbage, a kind belonging to the bunching class, is exceedingly useful. It is extremely hardy, and, as its name implies, produces thousands of shoots, rendering it a very valuable food producer for stock.

Portugal Cabbage, or *Conve Tronchuda*, supplies not only an edible Cabbage, but the midribs of its largest leaves rival *Seakale* in flavour and sweetness. Even the interior of the stems of Cabbages are not unfrequently served up with melted butter and relished as delicacies. The *Red Cabbage* must not be omitted, being valuable for pickling. In culture perhaps no vegetable requires more depth and richness of soil than the Cabbage. The ground should be well manured and most thoroughly worked, and the practice of alternating crops cannot be more necessary than in this case. All Cabbages are subject to a peculiar disease when planted repeatedly upon the same ground called "club." The stem gets gouty and scaly—the work of an insect which deposits its eggs on the substance of the stem where it joins the root. Dry weather and the character of the manure often aid this disease.

F. A. GARDINER.

PIPE HEAT FOR MUSHROOM BEDS.

I CONTEMPLATE making some alterations in our Mushroom house here where crops are grown between October and June, and would be glad to learn if any readers have ever succeeded well in growing Mushrooms without fermenting materials, which all Mushroom growers know are required, as the bed heat must be 80° or higher when the spawn is inserted. I can find no information on the subject anywhere, as in all cases, although pipe heat is considered necessary to keep up the temperature of the Mushroom house to 55° or 60°, fermentation is relied on for the heat of the beds. My opinion is that if we could use hot-water pipes for bottom heat, culture in winter would be both simplified and cheapened. It does not pay in private places to buy horse manure for Mushroom beds, and the home supply, except where hunters are kept, depends a good deal on the movement of the establishment, which also means the movement of the horses. Besides, the labour and cost of collecting the manure for any length of Mushroom beds and preparing it is considerable, not to speak of the chances to be run after the beds are spawned. For a bed of sufficient extent it requires many loads of manure, and in many, I may say mostly all, private gardens the stable manure is all that is allowed for the garden for all purposes. I find I could fill our Mushroom beds with a good compost of loam, manure, and leaves, &c, cheaper and easier than I could with stable manure alone, and if we could heat the beds steadily by means of hot-water pipes—which in most cases could be done quite easily—we should be independent of the stables, and be able to regulate the heat of the beds just like a Pine, Melon, or other hotbed. It is well known that pure stable manure alone or manure and leaves is not necessary for Mushrooms—the spawn will run and Mushrooms grow in loam alone, as they grow in the pastures, where their abundance is not so much determined by the quality of the soil as by the season. Our Mushroom house beds are arranged in tiers in the usual way, have slate bottoms, and I am sure I could heat each bed by means of a coil of pipes under the slates as easily and steadily as our other hotbeds. The question is, would it suit the Mushrooms? In theory there seems to be no doubt about it. The essentials in Mushroom culture are a proper compost and the right degree of heat and moisture, steadily regulated. The moisture I could easily manage with evaporating troughs on the pipes. Coals are cheaper than manure with us, the expense of heating would be little, and one should at all times be independent of horses for the main elements of culture. The dryness of pipe heat would be the only difficulty to overcome, but pipe heat itself is not injurious. I was once where a pipe ran the whole length of the lower tier of Mushroom beds at the back, and although the bed was insulated by a partition between it and the pipes, the heat of

the pipe was sensibly felt for a foot or 18 inches out, and the Mushrooms always came up first there, but did not continue to grow so long as on the other portion. The pipe was, however, not intended to heat the bed, and was badly placed in other respects, but it showed what could be done in that way by a proper arrangement. When I came here first one pipe for heating the house ran under the bottom bed. When the season was mild, and not much fire-heat was wanted, this bed did well enough, but when the pipes had to be warmed smartly it ruined the crop, the temperature of the bed getting much too high; so it was taken out. Provided the spawn is fairly good, Mushrooms seldom fail if the spawn is inserted at a temperature of 80°, and the temperature is allowed to decline steadily, but slowly, from that date for the next month; but where fresh beds have to be made up in the same house and the walls are not thatched or double built it requires great care to keep the temperature steady. Another advantage of pipe-heated beds would be that when a bed did not succeed through bad spawn or any other cause it could be re-spawned again and started afresh without delay, whereas by the present method all the making, &c., has to be done over again.

There would be no objections, of course, to using stable litter for heated beds, but it would not be essential. Pure loam would do as well, and perhaps better, as the spawn runs in the loam as freely as in any other medium, and much of it is needed, as it is to surface beds. J. S. W.

VARIETIES OF RHUBARB.

In your issue of the 19th ult. "A. D." makes some remarks on Johnstone's St. Martin's Rhubarb, which, we believe, we were the first to bring prominently before the public, and which he says is the same as Early Red. To show the origin of this variety, and also to clear ourselves of the charge of "having sent out as a new thing a sort that has been in commerce for years and universally grown," we give the following extract from our circular of 1869, the year in which this Rhubarb was first advertised: "The raiser describes it as one of a batch of seedlings from Victoria; the seedling plant was a fortnight earlier than any of the remainder of the lot, and grown beside Prince Albert and Linnaeus, always ten days earlier than them, and giving a larger quantity of superior stems than either of these varieties. It forces better than any Rhubarb I know and has a splendid colour." This was communicated to us by Mr. W. W. Johnstone, who raised the Rhubarb in question at St. Martin's Abbey, near Perth, and from whom we purchased our stock. He is now nursery manager to Messrs. F. & A. Dickson & Sons, of Chester, and can, if necessary, corroborate our statement. Before advertising it we placed it for trial in the hands of several large market gardeners and others well qualified to judge of its merits. We were strongly advised by them to offer it to the public, and the large demand we have had for the roots, as well as the many testimonials we have received concerning it have amply justified us in doing so. We do not know who "A. D." is; he may have had the Rhubarb from us, but we doubt it; he appears to go upon what he has seen at Chiswick, and by his own showing more sorts than one seem to be grown there under the name of Johnstone's St. Martin's. How, then, can he be certain of its identity? W. P. LAIRD & SINCLAIR.

Dundee.

Pea prodigies.—Few gardeners believe in sowing early varieties of Peas for late crops I should think (p. 454) except when it is too late to sow late kinds; but few were aware, I imagine, either that early Peas were "too tender" for late crops, as Mr. Muir asserts, their principal characteristic being their hardiness. Early Peas will grow when late kinds, especially marrows, will rot in the ground, and they will endure the hardest frosts above ground, which late ones are injured by. As for the Ne Plus Ultra Pea being third-rate, the Chiswick trials revealed that variety under, I

believe, ten new names, which does not speak ill for it. As an all-round kind I have found none to surpass it as a main mid-season and late cropper. It does not bear pods the whole length of its stem, and I would be almost inclined, about the month of August, to make a journey to Glamorganshire to see the sorts which Mr. Muir says "could be named that do." I never saw any tall Pea like Ne Plus Ultra that was "clothed with pods from the ground upwards," nor do I think anyone else ever did. The length a Pea will bear depends on the treatment and the room the stem has, but 3 feet or 4 feet is not bad. One of the distinguishing differences between an early Pea and a late one is that the first bears near the ground and the other does not. However, if Mr. Muir will at any time during the summer find and send to THE GARDEN office a single Pea straw of any late sort of the habit of Ne Plus Ultra (with which the comparison is instituted) "clothed with pods from the ground upwards," I will give in. Such prodigies should be seen as well as heard of.—J. S. W.

A VISIT TO BODNANT HALL.

In the formation of a home nursery at Bodnant Hall, near Conway, I think it was wise to choose a site at least 700 feet above the sea level. Last week I observed how robust and healthy the young trees were, notably Larch, Spruce, and Scotch Firs; some of the plantations formed with these plants reared at such an altitude have vigorous growth and compare favourably with those reared at a low elevation and consequently under more favourable conditions. I have always advocated the raising of strong, hardy plants suitable for the situations they are intended to occupy, and this can best be done by rearing the young plants at an altitude nearly equal to that of the intended plantation. At this place a speciality is made of alpine and herbaceous plants, hardy Ferns, American bog plants, and Coniferae, each of these classes being well represented. Amongst the new and rarer Conifers I noticed some fine, healthy young trees of *Picea nobilis*, *P. nobilis robusta*, *P. lasiocarpa*, *Abies Alcoquiana*, *A. Douglasi*, *Cupressus macrocarpa*, *Cedrus Deodara*, *C. Deodara argentea*, as well as several thriving specimens of the Umbrella Pine (*Sciadopitys verticillata*). The ornamental hard-wooded trees include a good collection of Japan Maples. Some of these are planted on the lawn in front of the house, where their beautiful foliage is shown off to the best advantage, and attracts the attention of everyone. The system of massing plants of one kind is here well carried out. In one place we find bold clumps of hybrid Rhododendrons in full flower, in another Ghent Azaleas, Kalmias, Pernettyas, Daphnes, Andromedas, and hardy Heaths, all flourishing in this Welsh mountain garden. Among alpine and herbaceous plants, I noticed that the Soldanella seems quite at home in the blazing sunshine, and, what is of rare occurrence in this country, reproduces itself from seed self-sown. Saxifrages and Sedums are here in abundance, each sort being grown in a patch or rather compartment of its own, something similar to what we noticed at Rockville, Mr. P. Neill Fraser's place in Edinburgh. There is a fine example of rockwork in course of erection by Mr. Pulham, of Broxbourne, an excellent imitation of Nature. A. D. WEBSTER.

Penrhyn, Bangor.

Hollyhock disease.—Mr Douglas says (p. 498) he is not likely to be troubled with this disease again, as there are no Hollyhocks, clean or unclean, anywhere near him. He may, however, be mistaken; it is not unclean Hollyhocks he has need to dread, but the wild Mallows of the hedges. In many places the latter weeds have been exterminated by the fungus, and in others the Mallows are covered with the pustules of the Hollyhock disease at all times of the year. When Mr. Douglas can write "there are no wild Mallows, clean or unclean, anywhere near," he may feel a little less anxiety for his pets.—W. G. S.

FORTHCOMING EXHIBITIONS.

JUNE.

- 12.—SOUTH KENSINGTON: Committee Meeting of Royal Horticultural Society.
- 13.—REGENT'S PARK: Second Summer Show of Royal Botanic Society.
- COLCHESTER: Annual Show.
- GUILDFORD: Annual Show.
- YORK: Floral Fête.
- 14.—LETON: Annual Show.
- 19 to 21.—LEEDS: Annual Show.
- WORCESTER: Annual Show.
- 26.—SOUTH KENSINGTON: Committee Meeting of Royal Horticultural Society; Show of Pelargonium Society.
- DISS: Annual Show.
- 27.—REGENT'S PARK: Evening Fête of Royal Botanic Society.
- CRYDON: Summer Show.
- 28.—SOUTHAMPTON: Show of National Rose Society.
- RICHMOND: Annual Show.
- 29.—CANTERBURY: Rose Show.
- 30.—REIGATE: Rose Show.
- BROMLEY: Show.

JULY.

- 3.—SOUTH KENSINGTON: Show of National Rose Society
- 3 and 4.—BAGSHOT: Show of Horticultural Society.
- 4.—WIMBLEDON: Show.
- TEDDINGTON: Show.
- 5.—DUBLIN: Summer Show of Royal Horticultural Society of Ireland.
- FARNINGHAM: Annual Show.
- BATH: Rose Show.

- 13 and 14.—CRYSTAL PALACE: Annual International Potato Show.
- 14 and 15.—ABERDEEN: Autumn Show.

NOTES OF THE WEEK.

APPOINTMENTS FOR THE WEEK.

- 12.—South Kensington: Meeting of the Fruit and Floral Committees; Evening Meeting at Linnean Society's Rooms, Burlington House, at 8 p.m.
13.—Regent's Park: Second Summer Exhibition of Royal Botanic Society.

ROYAL HORTICULTURAL SOCIETY.—The next evening meeting of this Society at the Linnean Society's Rooms, Burlington House, will be held on Tuesday next, the 12th inst. The following papers will be read: Mr. W. Goldring on "Cyrtopodiums;" Dr. Masters, "Notes on Conifers;" Mr. G. Maw, on "Crocuses;" and Herr Max Leichtlin, "Notes from Baden-Baden."

IMPROVED TIN BOXES.—We have received some excellent little tin boxes from the Tinplate Decorative Company, Neath. They are light and neatly made, having strong and simple little hinges, and they open easily. We should say they are excellent for those who have many plants or flowers to send by post. The decorated ones we do not care for; nor do we see the need of florid designing of any kind on a tin box.

BATTERSEA PARK.—The flowering trees here have been very fine lately, and their effects bold and charming from many points of view. It was sad to see the amount of smoke vomited forth by the engines in the railway goods yard near and many other manufactory chimneys. It was disgraceful to a city supposed to be the centre of civilisation. We shall never have tree or flower in parks with true freshness and beauty so long as this smoke pest lasts.

THE EDELWEISS.—An attempt has been made at the Grand Ducal Gardens at Schlackenweth, in North-western Bohemia, to create a sort of nursery for rearing young plants of Edelweiss, with the view of transferring them when sufficiently matured to the Keilberg, one of the mountains of the Erzgebirge chain, which divides Bohemia from Saxony. If the experiment succeeds, and the Edelweiss becomes acclimatised in the Erzgebirge, the flora of Northern Bohemia will have received a valuable addition.

THE MIXED BORDERS IN KENSINGTON GARDENS.—We have often called attention to these, and are sorry to see them this year as poor as ever. In that finely placed border in Kensington Gardens there is not one well grown or well chosen plant, bare earth and poor dwindling things everywhere. The trees and shrubs by the border, although overcrowded, give it many charms, and form a good background, if any good work were done with the hardy flowers to which it is devoted. Either it ought to be wholly planted with shrubs or made a decent flower border of. We trust none of our readers will mistake the work there for what is right with hardy plants.

ROYAL HORTICULTURAL SOCIETY.—Although one must deplore the times on which the Royal Horticultural Society has fallen, yet it is the bounden duty of all who are interested in horticulture to do what they can to help the efforts of a council which recognises that the advancement of horticulture is the main object of the society, a fact which many previous councils utterly ignored, and hence what in the current slang of the day is called "a new departure." The meetings at Burlington House deserve the support of all interested in the Society. There are many who possess in their gardens objects of interest who might be willing to submit them for such an occasion, although they would be unwilling to send them to the committee at South Kensington, considering them unsuitable; and if there are any sent, they may rely on it that the council would be only too glad to welcome such contributions.—DELTA.

Good room and window plants.—

From experience I can corroborate what "Veronica" says regarding the Aspidistra as a room plant and the Aralia Sieboldi as a window plant. I have had an Aspidistra lurida variegata in the same pot for nearly seven years. During that

time it has not lost more than three or four leaves, whilst its robust growth has enabled me to give a friend a piece of it which rivals its parent. The young leaves are beautifully striped and have a rich and glossy appearance. I have always kept it with a plentiful supply of water at the roots, in ordinary Fern soil, sponging the leaves from time to time as required. For the last two or three years I have, in filling my window boxes, placed an Aralia Sieboldi in the centre, with scarlet Pelargoniums, Lobelias, Ageratums, and Calceolarias flanking it, and very effective the grouping is, the rich green Palm-like leaf of the Aralia contrasting well with the scarlet and blue. My boxes were made of plain half-inch deal boards and covered on the outside with virgin cork, the cost being not more than three shillings each box.—A. H.

Birds and slugs.—As your correspondents seem inclined to deprive the blackbird of the credit of being a slug destroyer, I may mention that a tame one which has been left with me for some months to take care of devours the white, grey, and black slugs with avidity; as it evinces no objection to the slime of the former and the toughness of the latter, it is reasonable to assume that in its wild state the blackbird includes the slug in its bill of fare.—W. LLEWELLYN SALUS-BURY, Llanwern Lodge, Leicester.

—In reference to birds eating slugs, I have been making some experiments with three blackbirds and a thrush which I have in a cage. I first gave them some small brown slugs, which were eaten with apparent relish. I then got some large brown and black slugs from beneath a block of wood, and was not a little surprised to see them also disappear. The birds were not hungry, as they had an abundance of their usual food in the cage at the time. The slugs were seized and rolled about in the sand for some time, as a thrush will serve a snail before they were eaten. Worms are also pinched and knocked about a good deal before they are eaten by birds. Those who have a thrush or a blackbird in a cage should try them with slugs as I have done, and report the result. I may add that we have a great many thrushes, but few slugs in the garden.—G. A. PAS-SINGHAM.

—I have always understood it to be a well-known fact that the common thrush or mavis was a determined enemy to both slugs and snails—a fact of which I many times have had ocular proof, and therefore can safely confirm the popular belief in regard to this bird at least. But as to its neighbour, the blackbird, I cannot undertake to say as much. Although I have repeatedly observed blackbirds picking up small snails, I have never seen them touch a slug, and my opportunities are many, as we have plenty of these birds here, being in the midst of plantations. This, I may at once say, is also the reason why we have so many slugs and snails. One plantation runs along the outside of our garden wall, and the long, rough Grass in it makes a capital breeding place and shelter for slugs. Here they abound, and during their nocturnal rambles they even cross the garden wall, though a pretty high one, and thrushes, I am sorry to say, seem to be nearly extinct; we have had none here either this season or the last; the late severe winters which we have had have been fatal to them as well as to many of our other small birds. The robin is a good snail destroyer, but the best destroyer I have seen is a four-footed one, and an ill-treated one into the bargain—I mean the hedgehog. Hedgehogs I always encourage near the garden. It is interesting to watch them leave their resting places and ramble over the Grass in search of their prey; the amount of noxious vermin which they destroy is inconceivable. Ducks I have not much faith in, a much better pair being the gull and the lapwing.—R. STEVENS, Paston, Northumberland.

—I am of opinion that blackbirds and thrushes do eat slugs and nearly all kinds of grubs and ground insects, else why should they be so busy in turning over dead leaves and vegetable matter were it not to search for what they know have

their hiding-place under them. Of shell snails know they are particularly fond, for many times have I seen them cracking the hard covering to get at the juicy morsel within. Although blackbirds and thrushes are very troublesome in the fruit season, I always find them much less so after rain, as then they can get insect food, and while they can do that they prefer it to Gooseberries or Strawberries, which they leave for days at a time, and are only greedy after when the earth is quite dry. All soft-billed birds I regard as gardeners' friends, and though they may do a little harm for a time, the good they effect for at least nine months in the year more than counterbalances the mischief, independent of which they cheer us with their twitter and song. Instead, therefore, of destroying them we should encourage them, as nets are cheap enough, and by their aid fruit may be preserved.—S. D.

Columbines (Mrs. H. L.).—Send them to THE GARDEN office, addressed to the editor.

MESSRS. A. JEFFKINS & Co. have purchased Mr. J. Cat-tell's nursery at Westerham, and propose to carry on the business there as usual.

Seedling Pansy (Enquirer).—An excellent variety, but we cannot judge of its distinctiveness in the absence of others of a similar colour for comparison.

White Pansy (E. J. W.).—Try Messrs. Dickson & Co., 1, Waterloo Place, Edinburgh; or Messrs. Laird & Sons, of the same town.

Three-leaved Tway blade.—"J. M.," Channouth, sends us a specimen of this native Orchid (*Listera ovata*) having three leaves instead of the normal number—two. It is, we believe, a rare occurrence.

Fungus (K.).—The name of your fungus is *Agaricus precox*, common in gardens and pastures at this time of the year—called *precox*, we suppose, because it comes so precociously early in the season. We do not remember anything of its qualities for the table; some of its allies are said to be good to eat, but others are undoubtedly poisonous or offensive.—W. G. S.

Steam heating.—I forward you a copy of the monthly Proceedings of the New York Horticultural Society for March, 1882, which contains an article on steam heating by Mr. John Thorpe, which may give you the information you ask for in THE GARDEN (p. 310).—W. HAMILTON, Superintendent of Parks, City of Alleghany, Pa. [This was published in THE GARDEN, Vol. XXI., p. 361.]

Names of plants.—W. H. Winn.—1 and 2, we cannot name the double *Polyanthuses*; both appear to be good sorts; 3, *Spiraea hypericifolia*.—C. H. W.—1, 2 and 3, send better specimens with leaves; 4, *Potentilla*, send leaves; 5, *Erinus alpinus*.—C. D.—1, *Berberis Hookeri*; 2, *Iberis corifolia*; 3, *Lonicera etrusca*; 4, *Astrantia major*; 5, *Saxifraga granulata* fl.-pl.; 6, *Anemone narcissiflora*.—W. C.—*Allium Moly* (yellow), *Tradescantia virginica* (purple), *Geranium sanguineum*.—W. Forrester.—1, *Lencojum æstivum*; 2, send in flower; 3, *Cypripedium barbatum*.—J. C. C. (*Ingatstone*).—Poppy is *Papaver orientale bracteatum*; tree is *Ornus europæa*.—Mrs. Davidson.—*Cereus McDonaldiae*.—W. Borcham.—*Ornus europæa* (flowering Ash).—C. Parker.—1, *Abutilon Thompsoni variegatum*; 2, *Saxifraga sarmentosa*; 3, *Fuchsia microphylla*; 4, *Pelargonium denticulatum*.—T. N.—1, *Bryophyllum calycinum*; 2, *Begonia sanguinea*; 3, *Endelia globosa*.—H. O. R.—1, *Ranunculus aconitifolius* fl.-pl.; 2, *Jasminum Sambac*; 3, *Cyrtoceras reflexa*; 4, *Cypripedium barbatum*.

BOOKS RECEIVED.

Mushroom Culture for Amateurs, by W. J. May. L. Upcott Gill, 170, Strand, W.C.

The Apple in Orchard and Garden, by James Groom. G. Routledge & Sons.

Fruit Culture for Profit, by E. Hobday. G. Routledge & Sons.

Hardy Perennials, by J. Wood. L. Upcott Gill.

The Potato in Farm and Garden, by R. Fremlin. Routledge & Sons.

Report of the Metropolitan Board of Works.

Popular Guide to the Fisheries Exhibition. Pall Mall Gazette Office, 2, Northumberland Street, Strand.

CATALOGUES RECEIVED.

General Bulb Company's (late Barnaart & Co., Haarlem) Wholesale Catalogue of Dutch Flower Roots.

Messrs. Carter's (High Holborn) "May and June in the Garden." Choice Seed and Plant Catalogue.

"This is an Art

Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

NOTES AND READINGS.

HABITS OF TREES.—Trees, like plants of smaller size from seed, vary much in habit, and present us with a great variety of contour of top and branch, which by selection, as in the case of the Scotch Fir, might doubtless be perpetuated. The Sycamore presents the most noticeable differences; hardly two trees are quite alike, some being of a spreading habit, while others are compact and dense, bearing great masses of verdant foliage one upon another at this season of the year, when the woods are in their prime. The Beech and Oak and other trees differ in the same way. The Yew sports widely, no end of varieties being known to the nurseryman—some compact, some straggly, some growing in the pyramidal form naturally, and some round-headed, with all shades of difference between. Like a numerous family of children, hardly any two of the progeny from one tree have the same look; and the difference does not end here, but extends to the period of leafing and flowering. To the landscape gardener and woodman such differences of habit present themselves in different aspects. The first looks at the ornamental appearance of the tree, and the second at its timber, and prefers the straight-limbed specimen to that with the wide-spreading, umbrageous head so ornamental in our parks. There is room for both, however, and it will be acknowledged perhaps that the arboriculturist has not been so quick to take advantage of the sporting disposition of his trees as the gardener has been to fix special characteristics in his plants. The subject is one commending itself in the forester and nurseryman.

AURICULA FLORISTS.—Mr. Brockbank's remarks on alpine and herbaceous plants at Manchester thrust at the very foundation of the principles and practices of the florist, and Mr. Brockbank seems now to realise the possible consequences of his admissions. His present contention appears to be this—the alpine plants, &c., exhibited at the shows are forced, but the Auricula is not; therefore his condemnation of the former does not apply to the latter. A single question will show the falsity of this reasoning. The hardy plants at the Manchester and other shows consisted, numbers of them, of spring and other hardy plants quite as early as the Auricula. Will Mr. Brockbank explain, therefore, how, if the Auricula could be had in perfection at the National Auricula Show in April, without what he calls "forcing," the Manchester hardy plants could not, at the middle of May? The truth is the plants had not been forced any more than the Auricula is by florists, and they needed it less. One of the surest signs of forcing are insect plagues and diseases, and of these the Auricula fancier has enough, according to his own showing—plagues that are unknown almost on outdoor plants. It is open to Mr. Brockbank to withdraw or modify his remarks on exhibits of hardy flowers for the sake of florists and consistency; but their application to the Auricula florist cannot be disputed as they stand, and his words are about the truest and hardest that have ever been levelled at the "fraternity," who can ill afford to throw stones at others for not showing "alpine flowered naturally and in their proper character," and which have never been dressed or tampered with in any artificial manner.

FLORISTS AND THEIR FOIBLES.—I ought to be at least a match for the Rev. F. Tymons at the Scotch game of answering one question by asking another, but the exigencies of these "notes" prohibit me enlarging on the subject of florist's flowers at the length he does. I would just remind

him that what prompted him to take up the cudgels originally in defence of florists was my note on that exponent of the principles of "florists proper," who spoke of "the general beauty and perchance the perfume of flowers" as second-rate "points," appreciated only by the common herd; who dwelt with that complacent self-sufficiency, bred of his calling, on the superior wisdom and perceptions of the florist; who prated of the "law as to proportion" in flowers which florists have alone invented and they only believe in; and whose model of a perfect florist's flower was one which looked "as if it had been done by an artist"—meaning the man with the brush and colours, for when he spoke of an artist he meant the artist who paints those "precisely marked" ideals of the florist which are published annually in florists' catalogues. No true artist does that sort of work or paints in that style; but it is here the florist gives full swing to his fancy, and paints those standards of perfection that he has never yet been able to realise in culture. This is the florist I meant—who is not recognised nor owned, for very fear, by the cosmopolitan flower grower—the man who sets up standards of form and colour, &c., for which he has no authority in Nature or in art. Does Mr. Tymons acknowledge this florist, his teachings and principles, as his representative, or does he repudiate both? When he has candidly answered these questions I will answer his, as we shall both then be on clearer ground. At present it looks as if Mr. Tymons blows neither cold nor hot. As to his surmises about "Peregrine's" acquaintance with florists' flowers, it will suffice here to state that he is wrong, and has no means of knowing.

PACKING GRAPES.—*Appropos* of this subject it is interesting to read the theory of the matter as accepted in one of the most successful and famous Grape growing establishments in Britain, and recorded by a writer who we believe was the packer. It is from THE GARDEN of 1875.

Mr. — has sent many tons of Grapes to London without any packing between the bunches, and I have been told in Covent Garden that such packages arrived in as fine condition as if the fruit had never been packed. The baskets used for this purpose hold about 16 pounds of Grapes. Previous to placing the fruit in them a thin layer of paper shavings is laid over the bottom and all around the edges of the basket, after which filling is begun at one end, the bunches being put into position closely, and gently pressed against each other until the basket is full; on the slightest concussion the berries work themselves into the vacant spaces, and the whole becomes, as it were one *huge bunch*. The italics are mine. Clearly, big bunches are believed in for packing purposes.

MUSHROOM STALKS.—Mr. Wright, in his practical little book on Mushrooms, perpetrates an error when he says the stalks of Mushrooms cannot be eaten. They not only may be, but are eaten freely, and even a connoisseur could not tell the difference in the taste and flavour between the fresh portion of the stalk and the Mushroom itself. French cooks mostly all cook a good portion of the stalks and few or no cooks remove them wholly. They are perfectly wholesome, as we can testify by long personal experience, and stand in much the same relation to the Mushroom that the stem and branches of a Cauliflower do to the "flower," and which are always eaten more or less.

TOP v. BOTTOM GRAFTING.—It is now pretty generally admitted that a stock deprived of its own foliage is of little or no advantage to the scion, especially in the case of the Vine, as the root in a few years "becomes what the top makes it." Hence it is the correct thing now, with some practitioners, to graft Vines half way up and leave a limb of the stock as well; but some observations we have made lately suggest the idea that certain weak-growing and ill-finishing Grapes might be considerably improved by placing them between a good top and bottom of some other kind of Grape. Has any grower, for example, tried the Duke of Buccleuch on a Hamburgh or Muscat stock with a few feet of the same Vine

grafted on the upper end of the Duke as well? If the theory of the ascent and descent and elaboration of the sap has any force, there ought to be transfusion of blood by this plan, and consequent advantages to the middle portion of the rod, for "stock" and "scion" become rather confused in a case of this kind.

VIRGIN MUSHROOM SPAWN.—Mr. Wright, in his book on Mushrooms, dwells on the advantages of virgin spawn. It is by no means well known, he says, that the spawn is weakened every time it is transmitted from brick to brick—propagated by division, we apprehend him to mean—and that weak spawn from this cause accounts for many failures. The best crops are produced from spawn propagated from seed (spores), a very probable thing, it will be admitted. Good London growers find it to their advantage, we are told, to pay a guinea for a very small quantity of virgin spawn for their bricks. Many gardeners would like to know where such "perfect bricks" are to be had—propagation by division is, we fear, the rule. It is probable the London growers got their ideas from the French, as published in the "Parks and Gardens of Paris," where the value of virgin spawn was first pointed out to English gardeners, the French system in this respect being described as quite different from ours. The idea is worth acting upon at any rate.

PEREGRINE.

FRUIT GARDEN.

NOTES ON VINE CULTURE.

FOR some time before and after midsummer Vines require more attention than any other indoor fruits, and by carefully and timely looking after their wants at this season, the crops which they are now producing will not only mature properly, but a good foundation will be laid for next year's crop.

WATERING.—When Vines are in full growth, as all of them are just now, it is almost impossible to give too much water at the root. Even in borders badly drained anything approaching dryness should never be allowed to occur, and where the borders are as well drained as they should be, copious and frequent waterings are absolutely necessary in order to insure free and perfect development of wood, leaves, and fruit. There should never be any stated time for giving water. Some may make a practice of watering at the root once a fortnight, and others may do so when growth begins, when the fruit is formed, and again when it is half swelled, and that is all. But it is not half enough, and those who follow a rule of this kind would soon find out the advantage of being more liberal with water if they would only try the experiment for the sake of comparison. The appearance of the inside borders is often very deceptive. They look as if they were wet and in proper condition for the roots, but frequently they are nothing of the kind; the surface only is wet, while underneath where the principal feeders are they are dry. Vines in a properly made border would be greatly benefited by being thoroughly watered once a fortnight at the present time, while their roots are active. In poor soil or old borders, manure water may be given with advantage. One handful of the best guano dissolved in 4 gallons of water is a suitable rate at which to apply this stimulant. Sometimes it is spread on the surface and watered in, but this plan is not so immediate in its effects as when dissolved. All kinds of drainings from manure heaps are good for Vines and should be utilised. Borders recently made, or rich in manure, should not have manure water, but abundance of clean water; other artificial manures should be spread on the surface and washed down to the roots. We simply give a slight moderate or heavy coating according to the strength of the Vines and the condition of the border. Soot is one of the cheapest of all dressings which can be watered into a Vine border just now; of course it is not so nutritious as the best manufactured manures, but it keeps insects in check, and makes the foliage rich in colour.

STOPPING AND TRAINING.—Vines will not give satisfaction unless these operations are properly attended to. Stopping the shoots for the first time at the first or second joint beyond the best bunch is an old way of dealing with them, and no modern system is yet superior to it, but it may be well to point out that to follow it out successfully stopping should not be too long delayed. When the Vines are healthy and growing fast the shoots soon run out some feet in length; they should, however, be checked long before that takes place, and the best time to do this is immediately the position of the best bunch can be ascertained. The point of the shoot, being then young and tender, may be easily removed by means of the forefinger and thumb. In a week or two after this the bud behind the stoppage will push into growth, and this in its turn must be stopped. This should be done at the next formed joint, and when growth again breaks out, as it will be doing at the present time, the same operation should be repeated, and onwards after this no young shoots should be allowed to extend except those wanted for young fruiting canes next season. All Vines have a strong tendency to grow just now, but the growths must be checked and kept well in hand; allowing an innumerable quantity of small shoots to run all over the roof, and shade and smother the main shoots and fruit is a bad plan, productive of no good this year, and hindering the proper maturing of the wood for another season's work. The young rods for fruiting next year may be allowed to run as far up as the ordinary rods go, but when they have acquired a reasonable length it is better to restrict them so as to have substantial wood than encourage the formation of superfluous growth. Tying in the shoots must also begin as soon as stopping commences. Some shoots go the right way for tying on to the wires from the first and give no trouble, but others run straight up to the glass, or take an opposite way to that in which they are wanted to go, and it is these which take some training. At first they require to be carefully handled, as the slightest twist or strain will cause them to snap off at their union with the old wood. In the beginning they must only be gently drawn down a short distance and be tied there for a time, and in a week or so they may again be drawn down a little, and possibly on the third occasion they may be secured in their proper place. Crowding so that the leaves overlap each other should never occur. To avoid this, when the rods are young and the buds close together, a good many of them should be rubbed off. If shoots or spurs are emitted from the rods at a distance of 1 foot or thereabouts, there will be nothing objectionable in their distribution.

THINNING THE FRUIT.—This consists in reducing the bunches where too numerous and thinning the berries of those left for a crop. The question is frequently asked, What weight should I allow each Vine to carry, *i.e.*, how many bunches per rod makes a good crop? To this question I will not undertake to give a definite answer, so much depends on the age and strength of the Vines. A Vine might mature fifteen 2-lb. bunches; whereas half this number of 4-lb. or 5-lb. clusters would be enough. Where the crop was excessive last year, and the fruit did not perfect in consequence, the Vines should be dealt with more moderately this season, and when it has been discovered, as anyone may soon do, what weight each Vine or house will bear with impunity, adhere to that. No bunches, except very small or deformed ones, should be thinned off until after they have bloomed and the berries have become formed. In the case of Muscats especially, some of the finest looking bunches may fail to set properly, while the smaller ones may do so and be the most compact. These, therefore, should be allowed to produce the crop. Bunches composed chiefly of small berries, with few or no stones in them, should always be cut off, and, as a rule, where there are two or three bunches on one shoot, often the case, all but one should be removed, the principal object to be kept in view being to allow every Vine to carry a fair share of the general crop and have the bunches as evenly distributed as possible. After the number of bunches has been selected, thinning the berries

should be commenced. They should never be allowed to become larger than Peas before being thinned, and must on no account be permitted to become massed together. It is easy to thin them when loose and pliable, but when firmly packed the operation takes longer time, and the worst berries cannot be so well seen and cut out. In thinning, all the smallest sized ones should be removed, the inside of the bunch should be well cleared, and the outside berries, which go to form the size and shapeliness of the bunch, should be preserved. Those not thoroughly conversant with thinning are always inclined to leave too many berries, and the result is that before they are half swelled or begin to ripen they are so close that they cannot swell without bursting. In that case every bunch should be gone carefully over, and the berries which cause the pressure should be cut out with long sharp pointed scissors. The majority of Grapes will have been thinned by this time, but many bunches may still be too crowded and should be relieved.

INSECTS of all kinds must be kept in check if not wholly exterminated. Red spider, thrips, and mealy bug are the most troublesome. The two former eat the leaves, disfigure them, and check their growth. Mealy bug sometimes finds its way into the bunches and renders them unpalatable. In winter, at dressing and clearing time, mealy bug may be cleared off, but unless the most stringent measures have been taken to do this it will again make its appearance. One of the best ways of checking it is going carefully over the Vines now and destroying all that can be found. Frequent syringing, too, displaces it, and this is destruction to the red spider and thrips. Some insecticides are useful in these cases, but to work with them when the Vines are in full leaf and fruit requires special care, or damage may be the result.

GIVING AIR in proper quantity and at the right time is another matter requiring at present considerable attention. Many vineries suffer from not receiving sufficient care in this way. In large places the vineries are opened hourly if need be, according to sun and shade, but amateurs have often to ventilate in the morning, and in that position the ventilators remain all day. In cases of this kind I would recommend the roof to be slightly shaded, and at this season a little air admitted at back and front constantly. In this way it is astonishing how the health of the Vines can be maintained, but when grown without proper ventilation and kept too close insects are the only inmates of theinery which really prosper. When it is desired to force Grapes to ripen at this season, the best way is to keep up the temperature of the house by means of fire heat, and, at the same time, let abundance of air circulate through it. CAMBRIAN.

Market fruits.—Mr. Gilbert, in answer to some inquiries made concerning these, replies as follows: "Noblesse Peaches are to me useless except for home use, and now we don't eat Peaches. They have the best flavour, but that is all; no colour and bad setters; and indoors they do not look at you with that vigour which the modern Beatrice, Challenger, and Early Rivers do. In the market only the old stagers who know what flavour is will look at them. We have never yet sent a good ripe Peach to market; we only want size, colour, and croppers, and they must be so hard that they cannot be bruised. This is the rule with everything. Little Tomatoes fetch simply nothing and what people would say if they tasted a Grizzly, a black, or a white Frontignan Grape, I am at a loss to say. Marketing is what the old song says, 'the world is turned upside down.'"

Best black and white Grapes.—The best black Grape is doubtless the Black Hamburgh, which is grown in greater numbers than all other sorts put together; and as to the best white companion for it, I should say for general purposes Foster's Seedling. It would not be awarded a prize if placed in competition with Muscat of Alexandria, but it will beat the Muscat on almost

every point in which the average Grape cultivator requires it to do, *i.e.*, it will show bunches abundantly under almost any kind of training or pruning, and will set its fruit evenly and well in a greenhouse temperature. Its bunches, too, are handsome, being exceptionally well proportioned, and old Vines of this kind are just as fruitful as many kinds are at three years old. Give it good culture and time to ripen its fruit thoroughly until it assumes a golden colour, and there will be no lack of flavour. The question of what Grapes to plant can only be settled by knowing the special requirements of any particular case. But for a black and white Grape to suit the majority, Black Hamburgh and Foster's Seedling will be found trustworthy.—JAMES GROOM, Gosport.

The fruit crops.—Apples are at present a most promising crop; in fact the fruit is set so thickly as to resemble Cherries. We had a fine downpour of rain on the 9th, which refreshed the trees wonderfully. Strawberries are also a fine crop. Cherries flowered well, but get thinner every day. Plums are scarce, even Victoria. I have a few on a wall of the following sorts, viz., Victoria, Jefferson's, Winesour, and Golden Drop. Peaches on the open wall are very good, though they had no protection whatever. Of Gooseberries I have a very fair crop; but in not a few gardens in this neighbourhood they are almost a total failure. Our garden is well walled in and well sheltered. Currants of all sorts will, I think, be plentiful.—GEO. CARPENTER, Rydens, Walton-on-Thames.

Kieffer Pear.—I hope your readers will not be induced to plant the Kieffer Pear from what is quoted from the *Rural New Yorker* and other American journals on page 433 of THE GARDEN. I have had specimens of the fruit sent to me from various places, and have tested it carefully from the time it is coloured until it begins to decay. It is beautiful to look at, being very large, of a golden yellow colour with a red cheek. The shape is that of a barrel, or rather keg. The tree possesses great vigour and bears early; the leaf, like that of the Japan Pear (its mother parent) is large and glossy. Now all is said that can truthfully be said in its favour. The quality is such that it is only fit for canning or preserving like the Quince. Several nurserymen here have been praising it to the skies, and hundreds—thousands probably—have been induced to buy largely at a high price, believing, from several injudicious words of praise from well-known men, that its quality is excellent. The flesh is coarse, tough, gritty; in fact very little better than the Sand Pear.—E. S. CARMAN.

5002.—Litter for Strawberries.—The chief objection to the use of even bad hay as litter for Strawberries is that it is likely to be full of seeds, which will germinate freely and fill the beds with Grass and other weeds. If it is certain that no such results would follow, then hay may be employed as usefully as straw. But another objection may be raised against the employment of bad hay for such a purpose, and it is this—that bad hay has an objectionable fusty smell, and as the fruits lie upon it such smell may affect them. Such a result would very likely follow if the hay were put down just as the fruits were ripening, but it is obvious that if down long enough to get well aerated and washed by rains the bad smell would disappear. Indeed, such an objection might be taken to the use of long stable litter, of which vast quantities are employed for mulching Strawberry beds in the market gardens. A week's exposure to the air after it is laid down and one or two washings are found to remove all unpleasant smell, and to leave the litter innocuous.—A. D.

—The best thing to spread over Strawberry beds is small wood charcoal. It is a great protection to the fruit against snails and mould, and in wet weather prevents them from being covered with mud. I have used it with great success for the last five or six years, and I think that it has some influence on the quality of the fruit, for with the same kind of plants I certainly get better results than most of my neighbours.—J. H.

CYPRIPEDIUMS, OR LADY'S SLIPPERS.*

I HAVE chosen the *Cypripedium* as the subject of a few remarks, on account of its being one of the most interesting genera in the great family of Orchids, and one, moreover, that is numerously represented in gardens and becoming more and more popular every day. Among Orchids there are many genera that possess showier flowers than the *Cypripedium*, but few in which there is such a combination of ornamental foliage and handsome and singular flowers; consequently, the Lady's Slippers, as the genus is popularly called, find many admirers, and in most good gardens a few of them at least may be found in bloom throughout the year.

THE LADY'S SLIPPERS are also a very accommodating class of plants under cultivation; everyone may grow them. Those who have no stove may grow a few in the greenhouse, and those who have no house at all may grow some in the open air, and these hardy species are among the most attractive in the genus.

As time is precious and my subject a wide one, I can only deal broadly with the chief points of it; therefore I must confine my remarks to the main sections of the genus, its geographical distribution, and to the hybrids that have been raised in this country.

Of the 334 genera in the Orchid family, none, perhaps, possess such well marked characters as the *Cypripedium*; there is no likelihood of anyone confusing its species with those belonging to other genera. It is so distinct structurally, that some botanists have even gone so far as to strike it out of the order altogether. The most recent classification, however, places the genus as the type of one of the five primary tribes of the order. This tribe includes four genera, two only of which are in cultivation, namely, *Cypripedium* and *Selenipedium*, but the latter, for reasons that I will presently explain, might well be merged with *Cypripedium*, at any rate as far as garden purposes are concerned, as its distinctive characters are purely of a botanical nature.

A CYPRIPEDIUM may be at once recognised by the inflated pouch-like labellum or slipper, the only exception being *Uropedium Lindeni*, in which the labellum is prolonged into a tail-like appendage similar to the petals. Another remarkable character in *Cypripedium* is the two perfect stamens, whereas in all other Orchids there is but one developed. *Uropedium Lindeni*, which I have just mentioned as having an abnormal labellum, is also irregular as regards the stamens. It has three perfectly developed stamens; two are lateral, as in true *Cypripedium*; the other springs from beneath the stigma. Its anther is borne on a long stalk so as to bring it in contact with the face of the stigma, and thus fertilisation is effected. No other Orchid that I know has the third stamen developed, and in this case it seems as if Nature, by way of compensation for the loss of the slipper-like labellum, thereby preventing fertilisation by insect agency, had added the third stamen in order to enable the plant to fertilise itself. It is, I believe, the only instance in Orchidaceæ in which self-fertilisation is possible. It is a singular fact that no mention is made of this anomaly by Bentham and Hooker in their late revision of the order in the "Genera Plantarum," though Reichenbach gives full details of it in his "Xenia." I have examined some dozens of flowers, and find this character to be constant in every case. What should have been the third stamen in *Cypripedium* proper is transformed into a fleshy organ covering the stigma, and is called the staminode. As the shape of this staminode is very variable, it furnishes an important character in determining species. In some its outline is square, as in *hirsutissimum*; in others it is crescent-shaped, as in *barbatum*; but in the majority it takes a triangular form, as in *villosum* and all the hardy species. The other parts of the flower are much the same as in other Orchids, except that the two lateral or side sepals are united in one

piece placed under the labellum, the only exception to this character being in *guttatum*, which has these lateral sepals quite free. In several other species there is often only a partial cohesion of these sepals, notably in *levigatum* and in some of the hardy kinds. All the species are herbaceous perennials, and for the most part terrestrial. The majority are stemless herbs, producing tufts of evergreen leaves arranged one above the other in two rows. The rest are deciduous and have leafy stems.

THE GEOGRAPHICAL DISTRIBUTION of the genus is very interesting. When we consider how circumscribed the limits of most genera of Orchids usually are, the range of the *Cypripedia* is very remarkable. They are represented both in the Old and the New Worlds, and both in the northern and southern hemispheres. Some are found in the arctic regions of Siberia and the cold swamps of North America; others occur in the mountainous regions of South America, but the metropolis of the genus, so to speak, is in the hottest parts of Asia, especially in Further India and the surrounding archipelago. Though so cosmopolitan, no *Cypripedium* has, so far as I am aware, been found in the great continents of Africa and Australia, neither do they reach the southern latitudes of South America; in fact, all the members of the tribe appear to have sprung from a few local centres.

According to the latest computation in the "Genera Plantarum," *Cypripedium* numbers about forty and *Selenipedium* about ten species, or, in round numbers, about fifty in the two genera, but in this calculation several of the so-called species in gardens are no doubt only regarded as varieties. The greater number of the known species of both genera are in cultivation at the present time.

The whole of these species fall naturally into three groups, each possessing a set of characters peculiar to itself, and correlated by a distinct geographical dispersion, each, moreover, requiring separate treatment in cultivation. These groups may be conveniently called—1st, the temperate region group—species inhabiting the temperate parts of the Old and New Worlds; 2nd, the *Selenipedium* group—those confined to South America; and 3rd, the eastern group, or those inhabiting the Tropics of the Old World.

THE TEMPERATE GROUP numbers about a dozen species, all of which possess quite a distinct habit of growth from that of those of the other groups. All are herbaceous perennials, and all with four exceptions bear leafy stems ranging from 1 foot to 3 feet high. These leafy stems are deciduous; they die away in the autumn, and leave plump dormant buds which form the stems the following season. All the hardy Lady's Slippers bear more or less attractive flowers, and often showier than those of their tropical congeners.

This group has a wide geographical range, extending throughout the whole of the northern hemisphere, from the extreme east to the extreme west. The widest range is taken by *Calceolus*, one of our indigenous Orchids, but now almost extinct. This species occurs throughout the whole of Central Europe and as far north as Scandinavia. It is found in Siberia growing in company with the handsome *macranthum*, *ventricosum*, and *guttatum*, and in a modified form it is found in Japan under the name of *Atsomori*. A few species are found as far south as the Himalayas, and, still going eastward to Japan, *macranthum* occurs with two or three local species, namely, *japonicum*, a very handsome plant, and two rather inconspicuous species, *cardiophyllum* and *debile*, the last probably the smallest of all the *Cypripedia*.

Turning to the New World, we find in North America no fewer than eight species, all of which are in cultivation in our gardens at the present time. In the extreme west occurs *C. californicum*; then in the Rocky Mountains is found *montanum* or *occidentale*, and further eastward are found the white *candidum*, *arietinum* (the Ram's-head Lady's Slipper), *pubescens*, and *parviflorum*, the two latter related to our native *Calceolus*. In the Eastern United States are also found *acaule* and *spectabile*, or the Mocasson flower, the handsomest of all Lady's Slippers. Another extremely beauti-

ful species is *Irapeanum*, the most southern of the group. It is found in the savannahs in Upper Mexico, but it is so fastidious in its requirements as to baffle all attempts to grow it successfully. It may be best described as a gigantic form of *Calceolus*, but with the flowers wholly of a bright yellow.

A knowledge of the native habitats of any plant often furnishes a clue to the cultivator as to its requirements, and in the case of these hardy Lady's Slippers this knowledge is important. Generally speaking, they are all natives of swampy places, particularly the North American species, which for the most part affect peat bogs. In most cases they are found growing in *Sphagnum* Moss and decayed vegetable matter, but not in soil. As regards shade and sunlight, the species are somewhat irregular in their likings. For instance, the beautiful *spectabile* seems to abhor direct sunlight, and only thrives perfectly in partial shade; on the contrary, the little *acaule*, which is common in Tamarac woods, does not mind the sun. Other United States species, *candidum* and *arietinum*, grow in peat bogs, where the roots are perpetually wet, but the stems are fully exposed to sunlight. The two yellow-flowered species, *pubescens* and *parviflorum*, are not at all fastidious as regards shade or sunshine. They are found in dry as well as in wet places and in loamy soil, and seem to have a particular liking for stiff clayey banks. In this respect they agree with *Calceolus*, our native Lady's Slipper, which invariably affects calcareous soils, and under cultivation will not thrive well unless it is placed in a stiff loamy soil mixed with limestone. It is also rather partial to full exposure, though, as a rule, it is best to give slight shade. The Siberian species *macranthum* and its near neighbour, *ventricosum*, are the most difficult of all to deal with in gardens, but this difficulty arises, no doubt, from placing the plants in moist peaty bogs, whereas they require to be treated similarly to *Calceolus*. This species grows in company with *macranthum*, and importations of roots from the localities where they grow generally contains a large percentage of *Calceolus*. In the York Nurseries *macranthum* has been successfully grown and flowered this season in heavy calcareous loam, the same as that in which *Calceolus* is grown. *C. japonicum* is considered a very difficult plant to grow, but no doubt it would succeed if grown in loamy soil instead of wet peat. It occurs naturally in moist and shady Bamboo groves, and the fibrous wiry roots penetrate into a yellow loamy soil. The Siberian *guttatum*, which is perhaps the prettiest in colour of all the Lady's Slippers, being white and blotched with crimson, is found on the eastern slopes of the Ural Mountains. There it is even commoner than *Calceolus* or *macranthum*. It grows in Birch, Pine, and Poplar woods, where the soil is rich in humus, and constantly damp. It appears to be confined to the woods composed of the three trees mentioned. It grows in grass and moss, and seems to like the same treatment as that of *Pyrola* or *Epigæa*. The Pelican Flower, as *Irapeanum* is called, is found in Upper Mexico, at elevations of from 3000 to 4000 feet, and where the conditions are such that the plants are saturated with moisture at the roots while the stems are in active growth, but when these have died away the soil is dry, and thereby giving the plant a decided season of rest in winter. The ill success in cultivating these hardy Lady's Slippers may, in most cases, be attributed to putting all under the same conditions, generally in a moist shady peat bed, which suits some, but not others.

THE SOUTH AMERICAN or *Selenipedium* group numbers about a dozen species, nearly all of which we have in cultivation. They all possess quite a distinct habit of growth from other *Cypripedia*, with the exception of a few of the East Indian species. All have long sword-shaped leaves of thick texture and wholly green, and all bear tall, several flowered stems usually furnished with conspicuous leafy bracts. Their most important distinguishing character, however, is in the flower, the ovary or seed-vessel of which is three-celled, whereas in all

* A paper read by Mr. William Goldring at the evening meeting of the Royal Horticultural Society, Linnean Society's Rooms, Burlington House, June 12.

other *Cypripedia* it is one-celled. On account of this difference in structure, Professor Reichenbach founded his genus *Selenipedium*, but in gardens the species comprising it always have been, and probably always will be, classed with the true *Cypripedia*. There are other minor differences in flower structure in this group; for instance, in most of the other species the dorsal or odd sepal is as a rule the largest; but in the *Selenipedia* it is generally the smallest. Moreover, in nearly all the species the petals have a decided tendency to prolong themselves into tail-like appendages. An extreme case of this we have in *caudatum*, one of the most wonderful of all Orchids.

In this species the petals are excessively prolonged, sometimes measuring a yard in length. It is interesting to observe how rapidly these petals or tails are developed. When the flowers first expand they are only about an inch long, but during the four or five days following they attain 18 inches or 20 inches in length, and they have been observed to extend as much as 5½ inches in one day. A similar example of this lengthening of the petals we have in the curious *Uropedium Lindeni*, which, as I said before, differs from other *Cypripedia* in having a long-tailed appendage instead of a slipper-like lip.

The distribution of the South American group is somewhat limited compared with that of the other groups. Its headquarters are the mountainous districts in the north-west part of the continent, but outlying members are found in Central America, and one, the rare *C. vittatum*, is found even on the eastern coast of Brazil. A few species, not introduced, also occur in Brazil; *C. longifolium* is found in elevated districts of Costa Rica, and, coming southward, we come across its near neighbours, *Roezli*, *Hartwegi*, *Hinksianum*, and *Lindleyanum*, which so much resemble each other that many regard them as only geographical forms of one species. The beautiful little *Schlimi*, which has played such an important part in hybridising, a very distinct plant, is found near Ocaña, but the best variety of it, and also the white form, occurs in Antioquia. It invariably grows in rocky crevices, and usually where it is almost perpetually deluged by water splashing upon it. This hint should be taken by cultivators to grow the plant in a moist and not too warm an atmosphere, as it is so liable to attacks of thrips if kept too hot and dry. In New Granada the singular *Uropedium* is found in the districts around Lake Maracaibo. Further south, in Peru, in the Andean Cordilleras, is the home of *caudatum*, which also occurs in the more northern parts of the continent, but as a richly-coloured variety named *roseum*. The little Sedge-leaved Lady's Slipper (*caricinum*) was found by Pearce in Bolivia, and it commonly goes under the name of *Pearcei*. All the *Selenipedia* require to be grown in an intermediate temperature and in a moist and well ventilated house, as they invariably grow naturally at high elevations where a cool and moist atmosphere prevails.

THE EASTERN GROUP is the most numerous of all and, moreover, the most important from a garden point of view, as it has yielded the handsomest species we have in cultivation. This group numbers some thirty species, nearly all of which have been introduced. The species may be conveniently placed into two series, according to the character of the inflorescence. One series bears solitary flowered scapes, as in the well-known *barbatum*, and may be termed the *Unifloræ*. The other series includes those species which bear several flowers on a stem, similar to the South American *Selenipedia*, and may be termed the *Plurifloræ*, an example of which may be seen in *C. levigatum*. All the *Plurifloræ* have long, wholly green leaves of leathery texture, and seem to be the counterpart of the *Selenipedia*, except that the ovary is one-celled. There are five species in gardens belonging to this group, namely, *Stonei*, *levigatum*, *Parishi*, *Lowe*, and *Haynaldianum*. Another handsome species of this section is *glanduliflorum*, a native of New Guinea, but it has never been introduced in a living state.

The *Unifloræ*, or one flowered species, number about two dozen species, and these again may be divided into two classes according to leaf character, one class having plain leaves, as in *insigne*, the others mottled, as in *barbatum*. In the mottled-leaved group such a strong family likeness prevails, that the idea suggests itself that they are but forms of one or two very variable species. In all these there is a more or less distinct mottling of the foliage, and the flowers as a rule bear large upper or dorsal sepals, and almost invariably have wart-like glands on the edges of the lateral petals. To this group belong *C. barbatum*, *biflorum*, *Lawrenceanum*, *superbiens* or *Veitchianum*, *nigrum*, *Argus*, *ciliolare*, *Hookeri*, *Bullenianum*, *Dayanum*, *Petri*, *javanicum*, *virens*, *Burbidgei*, *Mastersianum*, *Curtisi*, *purpuratum*, *niveum*, and *concolor*. The green-leaf set comprises *villosum*, *hirsutissimum*, *Boxalli*, *insigne*, *Fairieanum*, *Druryi*, and *Spicerianum*.

These eastern species are confined to a comparatively limited area, and particularly the mottled-leaved series, which are almost restricted to Borneo, Malacca, Sumatra, and Java, the only outlying members being *venustum*, which reaches as far north as Nepal, and *purpuratum*, which is found in Hong Kong. Consequently, this race requires an abundance of heat and moisture in cultivation. The plain-leaved series with one-flowered scapes are all confined to the Continent, the most northerly species being the old winter-flowering *insigne*, which occurs in Nepal, and is therefore amenable to greenhouse culture. Coming south, the rest of the species occur in succession, including the dainty little *Fairieanum*, whose particular lair no one seems to know. The recently introduced *Spicerianum*, one of the handsomest of Lady's Slippers, comes from Further India, and is found growing in crevices of limestone rocks in positions where it is perpetually moist. The little *concolor*, so distinct from all other species in form of flower, has its native habitat on the mainland somewhere in Moulmein, and its counterpart, the beautiful little *niveum*, the only pure white Lady's Slipper, also occurs in this locality, but was first 'discovered' in the Tambelan Islands, a little group just off the mainland. Both of these species grow naturally in limestone rocks, but in cultivation the plants are none the better for limestone in the soil. The several flowered race are all insular, except *Parishi*, which occurs in Moulmein, and seems to be the counterpart of *levigatum* of the Philippines. *C. Lowe*, which is purely epiphytic, inhabits Borneo, and a slightly different form of it called *Haynaldianum* is found in the Philippines. The very handsome *Stonei* is also a native of Borneo. All the group require an abundance of heat and moisture.

Hybrids.

I now come to an important and interesting branch of my subject, and that is the hybrid *Cypripedia* that have been raised in gardens in this country, and which number nearly half a hundred up to the present time. No Orchids have lent themselves so kindly to hybridisation as *Cypripedia*, hence the large number of hybrids that exist, and of which several fine examples are before me. The aim of the hybridist has been twofold. He has sought not only to obtain variety, but has also endeavoured to infuse a stronger constitution into the weak growing species, or bad-doers as they are called, by crossing them with vigorous species. In both cases he has been very successful. He has produced wonderful variety, for none of the hybrids are like the parents from which they sprang, and in several instances the progeny is handsomer than the parents. The hybridist has also been highly successful in intercrossing weak with vigorous growers.

The hybridist's successes have been many, but he has also had numerous failures. As yet he has failed to intercross any of the hardy species among themselves or with either of the two other groups, though it has been attempted several times. Mr. Seden, one of the most successful of Orchid hybridists, tells me that in his attempts to cross the North American spectable with any of the tender species he has obtained swollen seed-pods, but

their contents invariably turned out to be nothing but chaff; at least, he has never succeeded in inducing any seed to germinate. Many attempts have been made to intercross the Old World species with those of the New World, but up to the present time no one has succeeded in flowering a hybrid between the two groups. There is, however, in Messrs. Veitch's nursery a presumed hybrid between *C. caudatum* and *barbatum*, the foliage of which bears unmistakable evidence of a cross between these two widely different species. Every effort is being made to induce this interesting hybrid to flower, but though eleven years have elapsed since it was first raised, it has shown no signs of flower. The flowering of this hybrid will no doubt be looked forward to with interest by botanists as well as horticulturists, for they will be curious to know how far the three-celled and one-celled character of the ovary is represented. It is a singular fact that every one of the hybrid *Cypripedia* is exactly intermediate between the two parents, so that by intercrossing two given species, the hybridist can pretty well judge what will be the features of the progeny. Of course some species intercross more freely than others, and the results of the hybridist's labour are not without value to the botanist, as they tend to show the relationship of species.

It is an important fact that every one of these hybrid *Cypripeds* possess a more vigorous constitution than their parents, and they are not only freer growers, but freer flowerers, and no more remarkable instance of this free-flowering character could be adduced than the now popular *Sedeni*, one of the finest hybrids yet raised. Some time ago I saw in Sir Trevor Lawrence's garden a huge plant of this variety bearing tall, branching spikes, and carrying fifty or sixty expanded flowers. Of course this was an exceptionally fine specimen.

This *Sedeni* is typical of a race of high-coloured hybrids, all likely to prove most valuable garden plants, as they are of such robust growth and bear such a long succession of flowers, that they may be termed perpetual flowerers. *Sedeni* was the result of intercrossing *longifolium* and *Schlimi*. The little *Schlimi* is the key, so to speak, of all the high-coloured hybrids of the *Selenipedium* race. These two species produced exactly the same variety when both were used as a pollen and seed parent, the brightest coloured of which type is *cardinale*, the result of crossing *Schlimi* and *Sedeni*. This may be termed a secondary cross, and the progeny seems to have extracted all the colour possible from both parents. *C. calurum* is another secondary cross between *Sedeni* and *longifolium*. By intercrossing *caudatum* and the Sedge-leaved *caricinum* or *Pearcei* *Dominianum* was the result, and by again crossing *Dominianum* with *Schlimi* the very handsome rosy coloured *albo-purpureum* was obtained.

It is now some fifteen years since the first hybrid *Cypripedium* was raised. This was *Harrisianum*, a cross between *barbatum* and *villosum*, and was raised by Mr. Dominy. Since then the production of these hybrids has been carried on at an astonishing rate until now they number nearly as many as the wild species. The most valuable hybrids have been produced by intercrossing the East Indian species, particularly the one-flowered and the many flowered races. For example, the finest hybrid that has been raised is *Morganæ*, which is remarkable as being almost the counterpart of the extremely rare and very handsome platytenium variety of *Stonei*, which has long, broad, lateral petals copiously spotted with black. This hybrid was obtained by crossing *superbiens* and *Stonei*. It is interesting to observe that the tendency to produce several flowers on a stem was prepotent in this case, and likewise in other instances of intercrossing the one-flowered and several-flowered series, such as *selligerum*, between *barbatum* and *levigatum* and *euryandrum*, which had for its parents *Stonei* and *barbatum*.

One would suppose that there would be but little variation among the individual plants produced from the same seed-pod, but such is not the case with these hybrid *Cypripeds*, and in several instances some seedlings are vastly superior to

others. For example, of the earliest hybrid raised by Mr. Dominy (Harrisianum), there is a variety named superbum, which is superior to it in every respect, and being somewhat scarce commands a ten times higher price than a plant of the ordinary form. Again, in the case of selligerum, it also has yielded a very fine variety, having much larger and more highly coloured flowers than usual, and is known as the majus variety.

In Messrs. Veitch's nursery, Chelsea, where most of these hybrids have had their origin, there is quite a host of others which have not yet flowered, but of which great expectations are entertained. Patience and skill are necessary in Orchid hybridising, for in many cases the seedlings are several years before they flower. In the case of Cypripeds, however, which have no pseudobulb to develop before flowers can be produced the case is different. Some of the quick-growing kinds, such as Sedeni and others of a similar nature, have been flowered within four years from the germinating stage. On the other hand, the hard or slow-growing types, such as caudatum and Stonei, do not flower until they are several and often a dozen years old.

The chief workers in the field of Cypripedium hybridising have been Mr. Seden, who has raised for Messrs. Veitch no fewer than thirty distinct varieties; Mr. Bowring, of Forest Farm, Windsor, has also raised some very distinct and handsome hybrids; likewise Mr. Warner, who has, unfortunately, lost the memoranda relating to the parentage of his seedlings; Messrs. Cross, Swan, and others have also contributed to the work. It is a noteworthy fact, moreover, that the raising of hybrid Lady's Slippers has been carried out almost entirely in England. I have seen but one Continental hybrid which was Dauthieri, much in the same way as Harrisianum.

LIST OF HYBRIDS.

	SEED PARENT.	POLLEN PARENT.
Aiasworthi	Sedeni	Roezli
albo-purpureum	Schlimi	Domini
Arthurianum	insigne	Fairieanum

vestitulum	barbatum	Fairieanum
Williamianum		

Birds v. slugs and snails.—In reference to this question I may state that in this locality, where blackbirds and thrushes are very scarce, slugs and snails are more plentiful than I have ever met with them before in districts in which birds are numerous. There can, therefore, I think, be no question that slugs form the greater part of the food of blackbirds and thrushes when procurable. I have repeatedly noticed after rain when worms, slugs, and snails were plentiful on the surface that these birds were not troublesome to the fruit, but in periods of drought, when short of what one may call their natural food, they would

go under fish nets or through any aperture to get at either Strawberries, Cherries, or bush fruits. Here after rain good sized bushes are quite weighed down by loads of shell snails that devour the leaves.—J. G., *Hants.*

PLANTS IN FLOWER.

MAGNOLIA TRIPTALA.—A hugo species was shown at the horticultural meeting the other night by Mr. William Wickham, of Binsted-Wyck, Hants, in a very fine state of flower, its enormous foliage being healthy and well developed.

THE ALPINE ASTER.—The ordinary purplish form of this plant, with its large yellow centre, is very pretty indeed on the table. Some flowers of it, sent us by Mr. Ware, are more than 2 inches across. The white form is also pretty. Asters of this type are valuable for cutting in early summer. The plant is very easily grown in any soil.

THE TREE LUPINE.—It is not the first time that we have spoken of this hardy Lupine, but some good spikes of its rich yellow, sweetly-scented flowers from Mr. Ware remind us of its value. It perhaps more legitimately belongs to the shrub division than to that of herbaceous plants. The scent is delicious, and might be excessive where a large quantity of it is planted.

THE LARGE ST. BRUNO'S LILY.—This is a noble flower for cutting, and, even in the hot weather we have lately had, lasts very well in a room. It endures all the better if the seed-pods were pinched off as the flowers "set." Its pure white bells are charming. Of the two plants perhaps the purest in flower and best in habit is the ordinary St. Bruno's Lily, but this large white one is a distinct gain, and associates well with the finer early summer bulbs.

DIANTHUS HISPANICUS.—Among a choice group of cut hardy flowers, exhibited by Mr. G. F. Wilson, Heatherbank, Weybridge, on Tuesday last, was this extremely beautiful Pink, one of the rarest species in cultivation. It is of slender growth, and bears flowers about 1½ inches across of an intensely deep crimson. We first saw this Dianthus last year in Mr. Wilson's garden at Wisley, and we thought it then one of the prettiest hardy flowers we had ever met with. It is a pity that such a desirable plant should be so rare.

JAMESIA AMERICANA is a rare neat growing American shrub, producing at this season numerous clusters of small white blossoms on the tips of every twig; so plentiful, indeed, are the flowers, that a good sized and well flowered specimen such as that in the herbaceous ground at Kew looks like a mass of white. It belongs to the Saxifrage family and is perfectly hardy. It is a pretty object, too, in the Hale Farm Nursery, Tottenham, where it appears to be perfectly at home on elevated mounds in the alpine garden.

LYCHNIS VISCARIA SPLENDENS FL.-PL.—This double-flowered variety is one of the best plants in flower at the present time in the Hale Farm Nursery, Tottenham, where it may be seen by the square rod, a perfect mass of bloom. The colour, a rich rosy purple, is very striking, rendering this by far the best of all the hardy perennial Lychnises. It grows from 1 foot to 1½ feet high, and produces its rosette-like blossoms thickly on the erect branching stems. A double variety of Lychnis dioica is also finely in bloom in the same nursery.

GUERNSEY IXIAS.—A gathering of Ixias sent to us by Mr. Hubert, Fountain Street, Guernsey, shows what beautiful colours exist among these Cape bulbous plants, and also how finely they can be grown in the genial climate of the Channel Islands. Mr. Hubert states that the flowers sent are from unnamed seedlings raised from carefully hybridised seeds. Most of them are remarkable for their large size and substantial texture, as well as for the large massive spikes on which they are produced. Some are particularly fine in this respect. Some of the flowers are a rich port wine colour, but the majority are white or creamy white, and mostly striped or blotched with crimson.

Some, too, are pale yellow, and nearly all have dark, almost black centres. In a cut state these Ixias are very valuable, as they last a long time in perfection, and if cut when only half the flowers on the spike are expanded, the rest develop quite as well as those on the plant. Ixias, Sparaxis, and similar bulbous plants are almost unknown in gardens as a rule, but they are a valuable and beautiful class of plants.

TORENIA RUBENS.—This is a near ally of the well-known *T. asiatica*, a favourite plant for suspended baskets. The new species has much the same drooping habit of growth and is also similar as regards the size and shape of the flowers, but the colour is deeper and somewhat richer, a circumstance which makes it quite distinct in appearance from the other. A well grown specimen of it in one of the compartments of the T range at Kew is a pretty object. It is in a hanging basket, its shoots, full of blossoms, falling gracefully over the sides.

HABRANTHUS PRATENSIS FULGENS.—A very fine spike of this hardy bulbous plant has been sent to us by Mr. Allan, Gunton Park, Norwich. There are five blooms on the spike, which is about 9 inches high. The flowers, which are 2½ inches in length, are brilliant orange-scarlet and very striking—indeed, one of the finest hardy flowers in cultivation. As Mr. Allan seems particularly successful in the culture of this rare plant, perhaps he could give our readers the benefit of his experience in that respect. This plant was figured in *THE GARDEN*, Vol. XIV., p. 514.

SCHIZANTHUS RETUSUS.—Some fine specimens of this showy annual from Mr. Crook, Farnborough Grange, remind us of its great value as a conservatory plant at this season, but how seldom do we meet with it grown as it should be for such purposes. Its light elegant growth and foliage and brilliant orange and carmine blossoms make it distinct from the ordinary run of early summer greenhouse plants. It is more showy than its commonly grown relative, *S. pinnatus*, the flowers being nearly twice the size. These beautiful half-hardy annuals receive as a rule but scant attention in gardens as regards their pot culture, yet when well grown there are few that repay so well the trouble of cultivation.

VERONICA GIRDWOODIANA AND PINGUIFOLIA.—These two Veronics are very beautiful with us this season. *V. pinguifolia* is growing on our rockwork, where it has stood for two seasons. It forms a dense, small shrub, and appears to be admirably suited for rockwork, as the plant seems almost to "nestle" among the stones. *V. Girdwoodiana* is flowering in the open quarters in the nursery.—**ROBERT VEITCH & SON, Exeter.** [Two very pretty hardy shrubs. *V. Girdwoodiana* is very twiggy in growth, and every tiny shoot is terminated by a dense cluster of purplish blue flowers, somewhat similar to those of our common Speedwell (*V. Chamædrys*). *V. pinguifolia* is a dwarf compact growing shrub, with small glaucous leaves, and with small clusters of white flowers having purple stamens.]

GARDEN IN THE HOUSE.

Double zonal Pelargoniums.—Amongst plants for furnishing the flower basket there is hardly any more useful, and certainly none more continuous or unfailing, than the double and semi-double zonal Pelargoniums. They are, however, only at home under glass protection, as even in mid-summer heavy rains soon spoil the blooms—the centre of the truss gets decayed before the outer blooms are expanded; but under glass they are really most effective, and for cut blooms where brilliant colour is required they are indispensable. This is the time to get up a stock for next winter's display. Young plants in 3-inch pots, if shifted into 5-inch ones and grown on in cold frames, keeping all the bloom pinched off, will make a fine show when dark days again come round. There are so many beautiful varieties of double Pelargoniums in various shades of scarlet, that it would be well-nigh impossible to say which is the best,

roofed pit if at command. Plunge them with their heads well up to the glass, let the minimum temperature range about 60°, and give sufficient atmospheric moisture to keep them steadily progressing throughout the winter.

PEACHES.—EARLY HOUSE.—When the buds begin to show colour a slight rise by day may be indulged in on bright, fine days; but a gradual fall back to 45° or thereabouts at night will be advisable until the flowers are perfected and begin to unfold, when more air and gentle fire heat will be necessary. Look well to the fermenting leaves on the internal border, as the humid warmth from these is so much better than that obtained from the hot-water pipes, and further, the necessity for constant syringing is greatly reduced, no small advantage in the dark, dull month of December, when complete saturation of the buds is not always desirable. If the roots have the run of an external border, this must be well covered with Fern or litter to keep out the frost, and tarpaulin may be used for throwing off snow and rain; but in these high feeding days an outside border attached to an early house is looked upon as a superfluity, the main points in the management of the roots of Peaches being good drainage, sound calcareous loam, frequently changed, and plenty of water at all times. If Strawberry plants, the forerunners of confusion in forcing houses, must be introduced, let them be well dipped in sulphur water to cleanse them from spider before they are taken in, then clear off the surface soil, ram well, and top-dress with stiff loam and old cow manure. When the most forward trees approach the flowering stage, fumigate the house once or twice with tobacco paper. At this stage it is just possible that no enemy may have appeared in sight; but so destructive is green fly when smoking is omitted, that an operation so simple and inexpensive should never be neglected.

SUCCESSION HOUSE.—Prune, cleanse, and tie in the trees as opportunity offers, and keep the house well ventilated until the time arrives for starting. The first week in January is a good time to close the second house, as the earliest varieties form a close succession to the latest in the early house, and as Peaches cannot be kept for any length of time after they are ripe, a careful selection of kinds that will follow each other in their order of ripening should be made for every house. Assuming that the second house has been stripped and the lights properly repaired and painted, there will be no fear of the buds dropping for want of water; but where the roof is a fixture, copious waterings will be necessary, and immediately after the fall of the leaf will be the best time for internal painting. Keep the latest houses as cool and airy as possible to prevent the buds from getting forward in mild weather, and avoid using them for tender plants which cannot stand a few degrees of frost. When all planting is finished, re-arrange the reserve wall, without which a set of forcing houses cannot be kept going, and fill up all available spaces with young trees from the nursery.

VINES.—Examine inside borders in the early house as soon as the buds are fairly on the move, and, if necessary, give old Vines which cannot be over-stimulated a good soaking with warm diluted liquid; also mulch the roots with rotten manure, renovate the fermenting material, and let the temperature range from 50° to 56° at night, and 65° to 70° by day. As old Vines generally break well, direct syringing may be moderated on dull days, but young ones which have not been forced early will require more careful management, as it not unfrequently happens that the most prominent buds take the lead, and unless timely attention is devoted to bending down and sometimes rubbing out the terminal buds, unsightly blanks will be sure to mar the appearance of the house. When this stage of growth has been reached, strip the outside borders of Fern and shutters, and cover to the depth of 18 inches with fermenting Oak leaves. Make them very firm to keep in the heat, and replace the shutters above, but at the same time clear off the leaves.

LATE HOUSES.—Look over hanging Grapes two or three times a week, as this intensely damp weather is very bad for Alicantes, Gros Colmar, and Muscats, and one neglected berry soon mars the beauty of a bunch. Get rid of the foliage little by little, as it parts freely from the Vine, but do not take off any more laterals, at least where the Grapes are to be bottled, otherwise the wounds will give off moisture and colour when the bunches are taken to the dry atmosphere of the Grape room. Ventilate freely with gentle warmth on fine mornings. Keep the house quite close in foggy weather, and let the temperature range from 55° by day to 45° at night. Make a good selection of eyes from early prunings, and if young planting canes are wanted early in the spring insert in sods or small 3-inch pots before Christmas. Keep them in a cold frame for three weeks, then place them in or over bottom heat. Cut back to the required length or quite down to the pots yearling Vines intended for planting. Dress the cuts with styptic and keep them in a cold house until the time arrives for encouraging growth. If any lifting or border making in late houses is being put off until the Grapes are cut, take advantage of fine days for firing the Grape room and cut as soon as the leaves fall from the Vines; meantime get the compost properly mixed, ready for use, and protect from the weather. Prune mid-season houses, cleanse, paint, and put everything in working order, then throw open the ventilators at all times when the weather is not unusually severe.

KITCHEN GARDEN.

VEGETABLES FOR EXHIBITION.*

No work in the kitchen garden is more interesting than that of cultivating vegetables for exhibition. It is in many respects an unlimited subject, as the quality of the produce can never be too high, or cultivators and exhibitors too numerous, and they may belong to all classes, from the owner of a garden many acres in extent, to a cottager who only rents a small allotment. Where vegetables are exhibited, often extensively and successfully from any garden, it is a pretty sure sign that vegetable culture receives proper attention and that the soil is well tilled. No ground is allowed to remain empty in the garden of one who grows vegetables for exhibition, and everything which can be converted into manure is taken advantage of. Some say that when a cultivator begins to grow for exhibition, crops for every day use are made a secondary consideration, and that except at certain periods there is a deficiency in the supply, but that is a mistake, as crops throughout the year must be of the highest excellence to enable extensive selection to be made for successful competition. For instance, anyone wishing to exhibit a dozen Cauliflowers in June would never think of only growing a dozen plants to secure that number of fine heads, but scores, or even more as the case might be, and, therefore, a surplus of fine heads would be the result; and this would happen in the case of all crops at all seasons. There is, moreover, the desire which every exhibitor possesses of growing only improved varieties of everything, and the best show vegetables are also the best for table use; indeed, they cannot be otherwise. Veitch's Autumn Giant Cauliflower, for instance, is one of the very best for exhibition purposes, and a better Cauliflower for ordinary use could not be. Intermediate Carrot is vastly superior to the Long Surrey for exhibition, and so it is also for the table. The handsome smooth fruit of the Drumlanrig Tomato is better than that of distorted kinds, and Drumhead Cabbages would stand no chance, either in a show room or on a dinner table, with the variety called Redraes. The only exception to this rule may probably be found in Potatoes, as among these the handsomest looking, such as Interna-

tional Kidney and Porter's Excelsior amongst rounds, are inferior in quality to others less attractive in appearance. Still, many of the newer sorts such as Schoolmaster, Covent Garden Perfection, and others, are not without merit. Before success can be attained the

SOIL must be got into proper condition. Few crops can be brought to any great degree of perfection in poor shallow soil; richness and deepness in the way of tilth are necessary in order to secure perfect development. A deeply-dug and well-manured soil will always produce good vegetables, but a soil which may produce fine Cabbages, Cauliflowers, Brussels Sprouts, and similar crops may not be capable of growing beautiful, clean Carrots, Parsnips, Beetroots, &c., as while the former delight to feed on fresh lumps of manure, and abundance of it, the latter can only be had clean and perfect where the ground can be penetrated freely without causing the roots to emit prongs and rootlets, which they are apt to do in newly manured soil. All such crops should be grown in soil which was well manured the previous year. Heavy land may always be made suitable for roots by adding sand, road scrapings, or leaf soil, and insects, which are so injurious to some crops, especially Carrots, may be prevented from doing much harm by the judicious application of soot, lime, or salt. Potatoes can only be had of the largest size by the aid of plenty of manure. Peas, too, delight in abundance of this stimulant, and so do Onions, Leeks, Broad Beans, and Celery. Leeks for show cannot be too large, and the more blanched the stem is the better. Onions can never be too large, provided they are good in shape and perfectly solid. In spring and early summer autumn-sown Onions are best for exhibition, but after the month of August spring-sown ones, if well grown, are generally the best. Celery, when strong, spotless, and well blanched, is an excellent vegetable for exhibition, and a good dish of it always commands attention. An ordinary amount of manure will grow Celery more firm and crisp than a superabundance of it. Of water it can scarcely have too much, and the soil with which it is earthed up should always be quite free from grubs, as it is these which disfigure the stems. Soil which will produce clean Carrots will always grow perfect Celery, and with us these two crops are never grown far apart. Undue crowding must be strictly avoided in growing vegetables for exhibition, but at the same time it is quite unnecessary to allow more space between the rows or plants than is really wanted. Onions, for instance, grown 6 inches apart should just be as fine as any which could be produced at 12 inches apart. Timely attention in the way of sowing, planting, and thinning are important points, and good results are not so much a question of space as of system and order. Unsuccessful exhibitors who have never given their vegetable crops due attention often think and say, when they see some high-class vegetables shown, that more means than can be commonly employed have been taken to produce them, but in the majority of cases that is not so; there is, indeed, no secret whatever in the matter of growing good vegetables; all they want is sound cultivation, care, and attention. Some crops may be stimulated by strong manures, and these may be the means of forcing certain things into prominence, but to depend on stimulants to produce all kinds of vegetables fit for exhibition is a great mistake. Artificial manures are deficient in sustaining powers, and therefore both crops and soil would ultimately suffer were no other manures used. Fertilisers, in the shape of top-dressings or manure water, may be employed with advantage at certain times during the season, especially in over-dry or poor soils, but I would never recommend anyone to grow show vegetables in such a, if I may be allowed to use the term, spasmodic way. The mainspring of success does not rest on such fits and starts, but on the general high condition of the soil—the result of good cultivation. Quality must be the sole characteristic of vegetables for exhibition, and this can only be obtained by steady, persistent growth.

* A paper written by Mr. J. Muir, Margam Park, Taiabach, S. Wales, and read before the Scotch Horticultural Association Edinburgh, December 4

IN SELECTING VEGETABLES for exhibition, preference should be given to those varieties that require most skill in cultivation. In unlimited collections specimens of everything may be shown, but where prizes are offered for collections of six, nine, or twelve sorts; only the choicest should be taken. A good collection of six kinds should consist of Peas, Kidney Beans, Cauliflowers, Tomatoes, Potatoes, and Carrots. In the case of nine dishes I would add Cucumbers, Celery, and Vegetable Marrows, and in that of twelve Turnips, Globe Artichokes and Leeks or Onions. Larger collections should include Broad Beans, Runner Beans, Asparagus, Beetroot, Cabbage, Brussels Sprouts, Parsnips, Salsafy, Savoys, Lettuces, &c. Rhubarb is sometimes shown as a vegetable, but it is not distinct enough to make a good dish. In single dishes a number of Cabbages or Savoys would stand no chance of being placed before good Tomatoes, Celery, Carrots, Cauliflowers, Potatoes, and similar produce, and in order to exhibit successfully attention must be paid to these matters. Over-grown vegetables or those past their best are not suitable for exhibition; they should be just on the eve of their prime, and it must never be forgotten that quantity can never make up for want of quality. In a really first-class collection of vegetables every dish should be good enough to win were it placed in the single classes, and unless that is so disappointment is sure to be the result. One of the best collections of vegetables I ever exhibited was shown at Gloucester in 1880, when four Cauliflowers beat twenty-four, and six Onions weighing 24 ounces each were preferred to heaps of two dozen. These are instances of quality being of more importance than quantity. A plan often resorted to is to show collections with one or two good specimens in each dish and the remainder inferior—an unprofitable mode of exhibiting. In preparing vegetables for exhibition, all superfluous matter in the form of loose leaves should be trimmed off and only the useful parts left. Roots should be washed clean, but any kind of polishing should never be attempted. In dishing up and arranging, no particular plan need be followed, but everything should be shown off to advantage. All kinds of salad plants may be included, but, with the exception of Cucumbers, none of them can be shown to win against good vegetables of the ordinary types. At many shows, however, there are salad classes. Cucumbers, Lettuces, Endive, Radishes, Mustard and Cress, Beetroot, and Celery are amongst the chief subjects which come under this heading. Cucumbers should never be too old when shown; young and tender specimens alone merit a prize. Fruits from 12 inches to 20 inches in length are generally preferred to yard long ones. Lettuces should be crisp and firm and always well blanched in the centre. The Batavian Endive is the best, but this is chiefly used as a winter salad. Radishes may consist of both the long and short-rooted varieties, and they may be red or white in colour, but they must be clean skinned and firm at the core. Apart from Celery being a first-rate vegetable, it must be included as a salad, and when well grown carries great weight in any exhibition. The

IMPORTATION of vegetables into this country is very considerable, and the only way to lessen it with advantage is to improve and extend vegetable cultivation. At exhibitions, as a rule, vegetables are not fairly dealt with. I have often seen more money offered for half-a-dozen Pelargoniums than for a dozen dishes of the best and choicest vegetables. Let us hope, however, that improvement in this direction will soon be forthcoming, and that ere long awards for good productions in the way of vegetables will not be left to be wholly made by our leading seedsmen.

Bliss's Abundance Pea.—A dried specimen of this Pea, thickly covered with pods, has been shown to us by Messrs. Howcroft & Watkins, Covent Garden. It seems to belong to the same class as the American Wonder, and is evidently equally prolific. It is a dwarf Pea—a cross, it is said, between Little Gem and Champion of England.

Autumn Cauliflower.—"J. S." (p. 436) is perfectly right as to Veitch's Autumn Cauliflower being one of the best of vegetables and distinct. "W. I." (p. 495) has evidently not grown the true variety of Eclipse, otherwise he would not assert that it is an exact counterpart of Autumn Giant, and yet he contradicts himself by saying that Dickson's Eclipse is fit for use two or three weeks in advance of the other. How, therefore, can they be counterparts? We maintain that our Eclipse is perfectly distinct in foliage, being much more self-protecting, dwarfer in growth, growing almost close to the ground, facts which have been proved by gardeners who have grown the two varieties side by side for years. We do not detract from Autumn Giant its legitimate value; both varieties have their distinctive qualifications and good properties.—DICKSON, BROWN, & TAIT, Manchester.

THE FRINGED BUCKBEAN.

LIMNANTHEMUM NYMPHÆOIDES, known more commonly as *Villarsia nymphæoides*, is one of the loveliest of British water plants. It merits

The Fringed Buckbean as it grows naturally; flowers yellow.

introduction to our ornamental waters, in which its cultivation is so easy that no attention is required after it has become established. It is a creeping perennial, the flowering-stems of which float far and wide, and bear leaves like those of a Water Lily, but smaller. They are prettily dappled with red-brown, or are even almost entirely of that colour, instead of green, and amid these sparkling spots on the water the flowers appear during July and August. They are funnel-shaped, about an inch across, bright yellow, and fringed. It grows from Norfolk and Gloucester to Sussex, and is naturalised elsewhere, but it is rather rare in England. In Holland it is much more common. There large tracts of canal are covered with its beautiful leaves and flowers. It is not at all like the Buckbean, as its popular name would indicate, but it does belong to the same Order, though few would think it a Gentianwort. The plant which it most resembles in general appearance is *Limncharis Humboldti*, a lovely aquatic, which may be seen every year in the Victoria tank at Kew, but they are not related, as the *Limncharis* belongs to the Alismaceæ, the same tribe to which the flowering Rush or *Butomus* belongs.

R. I. L.

Goat moth (*Cossus ligniperda*).—The larvae of this insect are found in many of the Oak trees in this neighbourhood. Their whereabouts can easily be detected by the powerful odour and moisture exuded from their burrows. From an Oak here 2 feet of rind fell off the trunk, which

is full of holes as large as one's finger made by these larvæ. On examining these holes I found about a dozen of the larvæ half their natural size. The part of the tree in which they are deposited is sure to decay; only Oaks are affected here as yet.—W. RICHARDSON, *Bessborough, Piltown*.

FRUIT GARDEN.

OUTSIDE V. INSIDE VINE BORDERS.

I HAD hoped that the article on this subject by Mr. Clayton in *THE GARDEN* (p. 217) would have led to a thorough discussion of this matter, but apparently everybody is contented with his own practice. I said everybody, but I do not mean that to include myself, else I should not be writing this record of my experience in regard to both sides of the question, that is, "outside and inside." And, first, I must ask to be allowed to shirk the Phylloxera part of the subject, and that for the best of reasons, namely, that I have hitherto been fortunate enough not to have had a visitation of that

pest, but, by the general scare there is about it, perhaps it will be best not to boast too loudly. I will, however, venture to say this much, that the idea of its prevalence is, I believe, really a scare, and nervous mortals would do well not to be too precipitate when told that the cause of their vines looking sickly is the Phylloxera. Do not believe it till you have a lively faith by a sight of the live insect. But now as to borders, outside or inside, which are best? Well, neither, but both are alike good, with this qualification, that season be studied—that is, as to what time of year the Grapes are to be ripe—when their different positions are determined. For early and late houses I unhesitatingly vote in favour of the borders being entirely inside, my reasons being that with regard to early houses no covering of borders is needed, either with the view of imparting heat to the roots, or of throwing off rain or snow; moreover, warmth, by watering with warm water when needed, can be imparted and retained far more effectually than were it applied to an outside border, not to mention the being able to do it just at the time when it would be likely to afford the Vines most benefit, this obviously could not be the case with outside borders that might be already unduly saturated by heavy rains. Apply the same rules to late houses, more particularly as to their immunity from over-saturation or the chilling effects of a heavy snowfall, together with the non-need of border protection, and the advantages of inside borders must be apparent. I say nothing in reference to additional labour as to watering, &c.,

Victoria, Ferns often looking in the latter colonies as strong and stiff as if they were cut out of tin. On emerging from the bed of the creek you gain a narrow plateau or terrace on the side of the mountain, on which stands a humble, but picturesque shanty containing a "but and a ben," where reside Mr. Wood and his wife, sole inhabitants of these heights. Wood serves as guide to those who want one, and boasts of being able to find his way on the mountain blindfolded. In his unscientific way, too, he is well acquainted with the various native plants, and plies a little trade by carrying bunches of flowers and berries into Hobart for sale at hotels and such places. Very hospitable were this couple and very talkative, especially on the glories of

MOUNT WELLINGTON FLOWERS, the lady having quite an alarming flux of adjectives at her command; only on one topic did the communicative flow run more slowly. The information given about the locality of certain desirable plants was of a vague and useless kind, and I soon came to the conclusion that whatever plants I wanted I must find without a finger-post. "The Spring," as the hut and its immediate neighbourhood are called (for here are the mountain springs which supply Hobart with water), may be considered about halfway to the top, and the cabin professes to serve as a refreshment house for those who want refreshment. The staple is Dandelion beer, a really excellent drink manufactured by the woman of the house, and having an agreeable bitter and astringent taste. From the door of the cabin is seen one of the most enchanting views probably in the whole world. Over a steep forest slope of Eucalyptus in the foreground, the eye wanders to the town of Hobart and passes on to an extensive and varied stretch of river and foreland, island and bay, until in the far distance the filmy blue of the Tasman peninsula and the circular sweep of the ocean and sky-line bound the vision and round off a landscape picture of unrivalled beauty. The innumerable convolutions of land and water lie before you outlined with all the exactness of a map. The air of Tasmania and Australia gains by distance a depth of blue which I have seen nowhere else. At a short distance the film begins to form, and every successive height marks its distance by the increasing depth of tint, till the far-off ranges are covered with a mist of colour—a purple blend of amethyst and sapphire. Looking out over the estuary of the Derwent and away past the Iron Pot, over the expanse of Storm Bay, where many a blue foreland and peninsula lie defined by a band of white sand or shining foam, one thinks of dying Gaunt's

Precious stones set in a silver sea,

for there is the stone and there is the setting—sapphire in silver filagree. Inside the cottage were many bunches of berries and flowers, mostly of Ericaceous plants, in which the mountain is very rich. These are tied on at intervals to a long rod which Mr. Wood carries on his shoulders into town, where he disposes of them to his various customers, chiefly visitors. I saw in a glass in this cottage a flower, unfortunately past its best, of a very fine shrub called the Tasmanian Laurel (*Anopterus glandulosus*). It is usually a medium sized shrub, 6 feet to 10 feet high, though specimens have been met with as many as 30 feet to 40 feet in height. The leaves are long and bluntly serrated and are very stiff and glossy; it bears nodding racemes of white flowers three-quarters of an inch across. Though the shrub is plentiful on certain parts of Mount Wellington, I did not come across any specimens. It is hardly likely that such a distinct plant, even when not in flower, should have escaped my notice; however, I was able to procure a small healthy specimen in Hobart, which has made excellent growth like a young *Rhododendron* since it has been in my garden.

Behind Wood's cottage the mountain rises abruptly, and from this point straight up the side there is a rough track like the stony bed of a torrent, made by prison labour in the early days of the colony. It is a very rough track, but is easily seen in contrast with the surround-

ing chaos of boulders, scrub and fallen trees; and it requires only a scramble over a few roods of this pathless chaos to make one appreciate the luxury of even such a rough and stony track as this. Instead of turning off up this steep ascent behind the hut I kept on a much better made path which ran along the side of the mountain, failing to notice where the proper track diverged from it, and in this way I went quite two miles out of my road, which I had to retrace in order to begin the ascent at the right point. This mistake, which was very annoying at the time, eventually turned out the happiest of mistakes, since it gave me the opportunity of seeing several fine plants which otherwise I should not have seen and a piece of sublime mountain forest scenery—the very abomination of desolation, which no one who had once seen it could ever forget.

PAKEHA.

ROSE GARDEN.

FIXING ROSE SHOWS.

THE fixing of Rose shows is daily becoming a matter of greater difficulty. The fact is, and it is well to recognise it, Rose-showing is becoming more of a science and of a business every day. A certain number of cultivators—all too limited, perhaps—look upon the winning of prizes as the highest object of their ambition. To carry off these no toil is too arduous, no cost too heavy, no strain too severe. Rosarians in general are greatly indebted to these growers for show for keeping up Rose culture to the highest possible standard. Their toil and enthusiasm forces the Rose to yield up its best forms, colours, fragrance, size, substance. Judging them by results—that is, the quality of their Roses—they have their reward; and as nothing succeeds like success, so nothing can prove more satisfactory to this class of rosarians than the sweeping off of as many first prizes as possible. In this laudable endeavour, however, not a few of those growers for sale are sadly fettered and hindered by the inadvertence or thoughtlessness of societies or their officers in arranging two or more large Rose fixtures on the same day, or on days so close to each other, as to render the presence of the same exhibitors at both impossible. Some may consider this an advantage, as it spreads the prizes over a wider area, or, in other words, increases the number of prize-takers. But as the object of Rose shows should not be personal, but general, the best Roses only should always win, though these should belong to the same exhibitors. Hence the propriety of so fixing as many of the great shows as possible on such days as should render the presence of the best growers possible at them all. How this is to be done is rather a difficult matter. But "where there's a will there's a way" is a motto well known and generally practised among rosarians. Were the motto more generally acted on in the fixing of the days of shows, better arrangements might be made. Perhaps a conference of secretaries of Rose or horticultural societies might be held. The fixtures of last year might also be published in the Rose year book or annual. Better still, the secretaries of

THE NATIONAL ROSE SOCIETY might be advised of all the great Rose shows of the coming or current season, and with such data in their hands they would be in a position to render valuable advice concerning the fixtures of the ensuing year. Local secretaries might also attend the annual meeting of the National Rose Society, when such matters might be talked over and arranged. It is the more needful that something should be done in this matter, as from the growing practice of Rose and general horticultural societies of keeping their exhibitions open till eight p.m. or dark, exhibitors lose two days in attending one show. Without an extraordinary staff of assistants, and a supply of show boxes *ad libitum*, few rosarians can manage to be at the whole of the chief meets without a considerable loss of rest and of money. Could the country be divided into Rose centres, and in each of these all clashing of days be avoided, and the chief local events be kept as clear as

possible of the National, Crystal Palace, and other great metropolitan Rose tournaments, perhaps that is as much as is practicable.

STRINGENT RULES in regard to the times of entry and removal might also often be relaxed in favour of exhibitors from a distance, and some effort made to allow them to leave by the last train at night at the latest from any particular town or locality. It is really too bad, and almost akin to cruelty to animals, to coop up rosarians for a whole night in the thick of the season of Rose shows when a relaxation of the rule of removal by half an hour would enable them to be among their Roses at the dawn of the next day and winning fresh honours before noon, and so on and on perhaps for a week in succession. It must not be supposed for a moment that I wish to convert Rose showing into a monopoly more close than it is now; on the contrary, no one is more anxious to increase the number of prize-takers as well as of Rose growers. Still, in the interests of the highest Rose culture, it is of the utmost moment to remove every barrier out of the way of the best Roses winning the highest honours as often as possible. Those who have had most experience either as judges, reporters, or occasional exhibitors must know that such is not always the case, and that one of the chief reasons for this failure of justice and merit arises from the number of shows held on the same day, or too close to each other. This

EXCESSIVE OVERCROWDING of shows also lowers the merit of the blooms exhibited, especially by amateurs, for unless facilities are enjoyed it is difficult to cut several boxes every day in succession for a week or a fortnight or three weeks at a stretch. Finally, might it not be better for Rose culture, rosarians, and even the societies themselves, to have fewer shows and larger, giving larger and more numerous prizes? There seems a tendency to fritter away effect and influence by the undue multiplication of little goes in Rose showing. Societies as much as exhibitors are too often found struggling against each other. Better far often for the fostering of Rose culture and of horticulture in general if these small societies, when within reasonable distance, would concentrate all their forces and hold one great good show between them. In writing thus it must not be understood that I am deprecating village or cottagers' societies. No; I wish that each had its Rose, Gooseberry, Leek, Cabbage, or general vegetable, fruit, or flower show. But for rosarians, professional or amateur, the area of competition might often be vastly widened to the raising of the standard of merit, the increase of the general interest in Rose culture, the greater usefulness and prosperity of the societies concerned, and the greater comfort and higher honour of the exhibitors. D. T. F.

AMONG THE BRIERS.

THESE promise well this season. Unless in the coldest localities, but few were killed by the winter frost, which was mostly concentrated into March. The cold winds and dry weather that prevailed through April and part of May held them back, and gave the outlook of a late budding season. But this tropical heat by day of the last three weeks has pulled the Briers forward by leaps and bounds, and the rosarian will be busy budding in advance of cutting his show Roses. This rapid growth seems to have enabled the Briers to grow out of insect pests as well as weakness, and, on the whole, they have seldom looked better. Disbudding should be attended to at once if not already done, and all suckers removed so soon as sufficiently advanced to enable them to be removed bodily and completely. It is not good practice merely to cut off a sucker so soon as seen, or to break it off before it has sufficient substance to hold together back to its base. Such prematurely checked suckers will only grow again and produce crop after crop, or their suppression will force others on other portions of the roots. Whereas if a sucker is allowed to grow until it can be carefully traced to its base and wholly removed there is an end of it, and other crops seldom succeed to the first.

Of course in all disbuddings and removal of suckers a sharp look out will be kept for aphides and maggots. Though both these pests prefer Roses to Briers, neither are above feasting on the latter when the former are absent. It is most important that Briers should be free from insects before being budded, as otherwise insect pests quickly shift their quarters from the Briers to the Rose buds almost before the latter burst into shoots. Any Briers that are weakly, or may not have broken at all, should be cut over at the ground line. This forces a strong break at their base, which may grow into a shoot strong enough to be budded as a dwarf before the end of the growing season. Such vigorous shoots may also at times be left to form fair standard Briers for next year.

The present favourable appearance and forward state of the Briers favour the assumption that they will be ready for budding before the Rose buds are sufficiently advanced for transference to their new quarters in the Briers. But in most gardens more or less Tea or other Roses are grown in pots or on walls, and the buds of these will come in nicely for the more forward Briers. By the time all these are utilised and any spare material on early Roses converted into cuttings the majority of the buds on the Hybrid Perpetuals will be sufficiently plumped up for budding with a reasonable hope of success. At present the state of the Briers and the improving condition of the Roses promise a more than usually busy and successful budding season. D. T. F.

THE ODOURS OF ROSES.

THE odours of Roses (p. 517) are not all pleasant; but then they are so generally so, that it is hardly worth while giving prominence to the well-known fact that one family smells like bed bugs. The Austrian Briers are, however, comparatively little grown, and where they are their early blossoms and brilliant bronze or golden colours are most telling at a distance; they also bloom most freely when left in a semi-natural state. The single golden or copper-coloured varieties are the most useful for such purposes, and having little staying power, there is but little inducement to gather them. Besides, it is only when gathered or crushed that they become so offensive. Has "Nez" noticed that the double variety of the golden (I have never seen a double bronze) is less offensive in its odour than the single, whereas the double Persian is sweet in comparison with the Austrian and the closely allied and beautiful Harrisoni?—a fine, soft golden Rose introduced from America nearly half a century ago, one of the most charming of all our golden Roses, and fragrant as Primroses. We have had some perfect standards of the latter at different times, in which the weakly, almost unpruned branches have formed the most compact and charming heads, the weaker ones weeping thickly-blooming sprays of golden beauty and pleasant fragrance, the most popular as well as the earliest belles of the Rose garden. D. T. FISH.

New red Tea Rose.—A coloured plate of a new red Tea Rose named André Schwartz, raised by Mr. Joseph Schwartz, of Lyons, has been sent to us by Messrs. August Rötker & Sons, New York, who are distributing it. The colour, which is said to be darker than in the plate, is a rich orange-scarlet—a colour much wanted amongst Tea Roses. Therefore, if fragrant, vigorous in growth, and free flowering, this new Rose cannot fail to be an acquisition. It has the appearance of a Hybrid Tea, a class but yet in an incipient state; within a few years it is likely there will be a great number of varieties where now there are but few, and being crossed with Hybrid Perpetuals they will probably be harder than ordinary Tea Roses. Beauty of Stapleford and some others belong to this class.

Rose William Allen Richardson.—I was much struck by this Rose when I first saw it exhibited by Mr. House, of Peterborough, two

years ago, at a local show. In the bud state it is very beautiful, the colour, a coppery kind of orange, being almost unique. It is valuable for its early blooming habit. We have it on a south wall alongside Gloire de Dijon, and both have been beautifully in flower some time. I suppose I may call it a Noisette with a Tea scent. It grows freely, but has small slender wood and foliage. If it will only bloom freely in autumn it will be valuable for cutting.—E. HOBDAY.

ROSE GLOIRE DE DIJON.

IN a recent number of THE GARDEN it was stated that this Rose is not well fitted for growing as a standard. Neither is it if pruned in the ordinary way, as in the course of a few years it becomes so over-burdened with wood as to form a by no means attractive object. I have seen plants quite a yard across when cut back before starting into growth a mass of ugly branch-like growths, and so top-heavy as to require several stakes to support them. The orthodox method of pruning this Rose is to leave some half-dozen eyes where the wood is strong, so that the superabundant vigour is as it were sub-divided, with the effect of producing flowers instead of running away into sappy wood which yields no bloom. This repeated year by year has for result the ugly specimens one so often meets with. There is, however, one way of treating this Rose whereby very handsome specimens may be formed, and which in more ways than one will enhance the enjoyment derivable from the old Glory. Instead of pruning long cut-back wood to within one eye if there is much wood, and to two if the branches are comparatively few, growth will of course be strong, especially in the case of vigorous established trees, and when the shoots have made about a foot of growth pinch out the tops. This will naturally have the effect of causing laterals to push, each one of which will be sure to produce several good blooms later in the season of course, but all the better for that, as they will come at a time when good Roses are scarce. Last year early in October I had a standard Glory with nearly one hundred fine blooms on it, and it furnished flowers until the first hard frosts came. This plant had only been budded two years, and had been pinched in the manner described; it was a perfect picture. We can have plenty of Roses in summer; the scarcity comes at its close and in autumn, but a few plants of Gloire de Dijon managed in the manner indicated would yield a bountiful harvest at that time. J. C. B.

SLAG SAND V. SLUGS.

THE manufacture of slag sand is a patent. The price is 1s. 3d. per ton. A truck carries about six tons. It is a good plan to get two or three neighbours and share in a truck-load; this in the southern counties reduces the cost of carriage. The large slug (not the one which feeds on garbage), about 3 inches long (I forget its name), will go almost anywhere, and I despair of success in circumventing his depredations. As to the fawn coloured and little black slugs, the sand answers well, but not perfectly. For instance, I have a patch of plants consisting chiefly of *Edraianthus*, *Campanula fragilis*, *Dracoccephalus*, &c., adjacent to a moist border containing *Auriculas*, *Primroses*, and *Hepaticas*. The last is a good harbour for slugs, and it cannot be denied that the first named plants are well liked by slugs. By surfacing the patch with slag sand it has sustained no damage. There is a large class of rockery plants which we are advised, and rightly, to grow in moist vegetable loam and grit. I refer especially to the *Gentians*, *Primulas*, some of the *Saxifrages*, but I might go on to a great length. Last autumn I procured a supply of what is termed unfertilised leaf-mould (the surface soil of an old Oak and Beech rockery); with a composition of equal parts of slag sand and this mould I have satisfactory success. Elsewhere it has been pointed out that ordinary leaf-mould is of questionable use, not, as I am inclined to believe, from its unnutritive, but from its fungus-breeding properties. On another occasion I will endeavour to show how

those who have parterres and whose love for rockery plants is out of all proportion to the space at their command can make the most of their ground and at the same time minimise their watering difficulties, not forgetting the slug and earthworm. R. C. APPLETON.

Bar House, Beverley.

ROTARY VALVES.

THE Thames Bank Iron Company have patented a valve which they call the Reliance. It is simple in construction and very carefully fitted. All the

Three way H valve.

moving parts are of the best gun metal, and will not set fast or get out of order. The handle being the indicator, one half turn either way opens or closes the valve, and it cannot be strained or injured by overturning. It will be seen by the annexed illustrations that this patent as applied to what

Three way T valve.

are technically called H and T pipes dispenses with the necessity for the ordinary complicated three valves with their three handles which are often turned the wrong way and thus put out of order, the one handle having control over the three water ways of the valve.

Lawn mowers.—In reply to "An Old Lawn Mower" (p. 482), I would point out that I am ready to carry out the trial as stated by me in THE GARDEN May 5 (p. 415), subject to the reservation therein stated, and I fail to see why I am not entitled to know where he resides, as he plainly is afraid of the results of such a trial. Probably he cannot comply with the reservation named by me, and therefore wishes me to decline a trial on account of distance. Writing under a *nom de plume*, and giving no clue as to where he lives, I cannot of course state the terms of the trial any farther, but if he or anyone else likes, I will take a machine anywhere within 20 miles of London, at any date that will give me a week's notice, and cut any upstanding native Grass 6 inches high at one operation, i.e., the machine shall be passed but once over the piece cut, and the Grass shall be cut off clean, but of course it is not possible to have such a velvety appearance as on a well cut lawn.—W. J. MAY, *Walton-on-Thames*. [We saw the other day an Excelsior mower tried in the College Gardens, Dublin, on

Grass about 6 inches long, and the work done by it was anything but satisfactory. It had to be passed three times over the same ground before the Grass could be said to be properly cut. In fact, amongst Grass of the length just named it is useless, though a good machine on shorter Grass.]

NOTES.

THE ALPS OF NEW ZEALAND will doubtless contribute as much to the gardens of the future as the European Alps have done to those of the past and present time. I was glad to receive the other day, through a mutual friend, a very interesting little collection of seeds from the Rev. Mr. Greene, the gentleman who recently ascended Mount Cook, and among them I found a tiny plant of what may be called a kind of Edelweiss (*Gnaphalium grandiceps*). It seems the counterpart of the Swiss plant, but has short, rounded foliage, and as the seeds seem to be fully developed, I hope to be able to rear plants from them. Unfortunately, the ascent of Mount Cook itself, with its blinding snow-storms and dangerous glaciers, does not offer many facilities for the collection of either seeds or plants, but at the same time it is pleasant to know that this same New Zealand range offers to plant collectors, if not quite a new botanical field, certainly one but little worked up to the present time. Failing professional aid in collecting, amateurs who have friends on the spot might do worse than induce them to send seeds of such mountain or upland plants as may be now and then obtainable. Packed in boxes of dry earth, they would travel quite safely.

*

PLANT PORTRAITS. — To draw plants and flowers correctly is not so easy as it is by many supposed to be, and yet a good drawing of a plant is the best of all descriptions of it that one can give. The observations of Darwin and others have taught us that no twist or depression in a leaf, no wrinkle or wave in a petal, no curve or deflexion in a stem exists without that twist, or wrinkle, or curve having a meaning, a definite purpose and reason to be. I have long contended that to cut a flower or a spray from a plant and to "arrange" it ere it be sketched is fatal to a good and true likeness being obtainable. The practice is often convenient, I know, but it is none the less fatal in a great measure, and the true pose of leaf and flower is lost in drawings so made. Nearly all the flower pictures in works on florists' flowers are not drawings in the true sense, but simply coloured diagrams, and the same is true in a great measure of the pictures in botanical works also. The correct size of the leaf and of the flower may be given, but the living spirit of the plant is left out; in a word we have (as someone said of poor sculpture) the "animal," but not the "animus." If we are to believe thoroughly in evolution we must revolutionise the art of illustration as applied to botanical knowledge, or in other words we must learn to tell the truth ("the whole truth, and nothing but the truth") with the pencil as well as with the pen.

*

ST. BRUNO'S LILY. — Amongst hardy flowers this is just now most lovely. No white flower could well be prettier, since it has more purity and elegance than the true Lilies themselves. Bud and blossom are alike most dainty, and the much vaunted Bridal Gladiolus is a dingy or sulphur-white in comparison, however beautiful it may be when seen alone; and yet "comparisons are odious" when applied to flowers, since each has its own especial charm. This St. Bruno's Lily, with its elegantly crimped petals, is acceptable in many ways. It succeeds that queen of the Narcissi, *N. poeticus*, and, like it, opens out fresh and fair in water if cut in the bud stage. A tall Venetian vase with a few spikes of St. Bruno's Lilies arranged with their own elegant glaucous leaves has been much admired by people who know how to draw. The description of this plant was selected by Ruskin as his model of long-winded botanical lore in his "Proserpina." I wonder if he ever saw Parkinson's "Paradiseus." I am afraid not, or he

would have said something kindly of it in his own work.

*

APPLIED SCIENCE. — This is an age in which we hear much of science, but in our gardening practice we must depend on an accomplishment without which science is herself left stranded high and dry—I mean that combination of trained quickness of insight and sound judgment commonly known under the homely name of common sense. In gardening observation, attention to small details is everything. We must keep our eyes open. If I wanted to know what kinds of fruit trees to plant in a garden in any particular district or locality I should not look into trade lists or scientific books, but I should carefully observe what varieties were most fruitful in the neighbouring gardens. A friend of mine told me yesterday by letter that he had planted an orchard of 300 fruit trees, Apples and Pears, only ten varieties or kinds being admitted, but, he added, those ten kinds, as scattered here and there in our locality, have never missed a crop for the past ten years! This I have called common sense, but it is really applied science of the most valuable kind.

*

WHITE MARTAGON LILY. — How comes it that we so rarely meet with the white Turk's-cap Lily? So far as I can see, it is nearly if not quite as robust as the other varieties, and to my liking it is the handsomest, if we except *L. dalmaticum* Catani, which sometimes bears a spire of thirty bells on a stout leafy stem 6 feet to 8 feet in height. Yesterday I spent a most enjoyable half hour in a good old garden where this white Lily is quite plentiful, throwing up its nodding spires of pearly buds everywhere, among Rose bushes, Irises, near Currant bushes, and from clumps of Yuccas and Rosemary. These bulbs have been undisturbed for many years, and one reason of their having existed so long in this garden is, as I think, owing to their being grown in company with other plants which shelter and protect their early growth. The finest bulbs of Martagon Lilies I ever saw were grown in a perfect mat of root fibres belonging to a Privet hedge, and near to an Ivy-covered wall which sheltered them from too much rain during the winter season. Soils vary, however, and what one man can barely keep alive luxuriates elsewhere even if neglected.

*

ENGLISH NAMES. — This question of English names is too important a one to be "snuffed out by an article," however canonical the writer may be. I have never yet met with a tolerable argument against popular names. Everyone acknowledges the English names of Chaucer or Shakespeare, and this being so, I see not clearly how or why those of Turner or of Parkinson can well be repudiated. Here is an argument from p. 322 of THE GARDEN: "I must, therefore, enter my protest against the supersession of scientific [What is science?] names of plants except in those cases (which are not a few) where the English name is so thoroughly familiar as to be unmistakable." In other words, the intelligent reader is told not to recognise English names until they are recognised by others. The premises of this argument are wrong, for our argument is and ever has been that all plants with Latin names must have English names also. When the mass of the people ask for bread, we cannot afford to offer them a stone. "Supersession" is quite out of the question; all we ask for, all we claim, is a necessary and called-for addition to the duly recognised scientific or Latin or Greek name. All we ask is for our opponents to accept these premises as our own, and to take up their argument as best they may if they disagree with us.

*

FRINGED COLUMBINE is a very old and very pretty name, as I take it, for the tall growing feathery flowered species of *Thalictrum*; and of these the tall rosy and the sulphur coloured kinds are, as I take it, the most effective, producing as they do masses of flowers aloft on tall, wand-like stems, which have a most graceful motion in the summer breeze. The Rose variety is, if not

uncommon, by far the rarest, and was recently given to me from an old garden under the name of the "Feather Columbine." All the *Thalictri* are beautiful in early leafage even if not quite so showy in blossom as those above noted, and as such are well worthy of being more generally grown than seems to be the rule at the present time.

*

THE POET'S NARCISSUS. — It is simply astonishing how many there are, even among gardeners, who fail to recognise the many different forms or varieties of *Narcissus poeticus*; and yet one must not be too severe upon the gardener. I will quote from the *Gardeners' Chronicle* of June 2, 1883, p. 706. Under "Answers to Correspondents" we read: "*Narcissus poeticus* (A. Brooks).—This species does not give a succession of flowers, and its season is soon over; but still they do not always go off as soon as yours have done. Have you any reason to suspect foul play?" I never like to disagree with the "*Chronicle* of the gardener," but in this case I do so in the interest of an old friend, who is not quite so black as the above extract would lead one to suppose. Here with us *N. poeticus* is in season from the second week in April until the first week in June, the varieties opening in this order: 1st, *N. stellaris* or *N. angustifolius*; 2nd, *N. ornatus*; 3rd, *N. grandiflorus*; 4th, *N. poetarum*; 5th, *N. recurvus*; 6th, *N. poeticus*; and 7th, *N. poeticus* fl.-pl., which, notwithstanding the dry, hot weather, is still in bloom. All the *Narcissi* are extremely sensitive to hot sunshine and dry winds, or, as a reporter of a London daily recently wrote of them as exhibited at South Kensington, "of varieties of Daffodil, some are strangely pale, some double-ruffled, and of *Narcissi* (surely the most fragile flowers ever grown) some seem fainting away, evaporating into air as you look at them." Then have we not Herrick's "Fair Daffodils we weep to see; you haste away so soon." Alas! no foul play is needful to make such beauty leave us.

*

ST. BRIGID'S CHRISTMAS ROSE (*Helleborus niger* var. *angustifolius*). — I have further to say of this plant that on no account must it be confounded with the great Christmas Rose (*H. niger maximus*), a totally different plant altogether, and further it is yet a matter of doubt as to whether Miss Hope ever saw St. Brigid's variety, since at least one noted trade grower tells me it at present seems quite distinct from the *H. niger angustifolius* he obtained from Aberdeen. As I have before said, its chief characteristics are robust habit (healthy clumps are 18 inches to 2 feet in height on good strong soil), total absence of any speckling or red colouring in the petioles, flower-stalks, or leaves, which, when young, are of a bright, deep glossy colour, reminding one, in tint and in texture, of the foliage of *Aucuba japonica* vera when well grown. The flowers are as large or larger than those of *H. niger maximus*, pure white, and freely produced. Apart from this there is a distinct general appearance about this variety which at once distinguishes it from any other form of *H. niger* whatever. It now seems probable that both Mr. Barr and Mr. Ware will flower St. Brigid's Christmas Rose next season side by side with other forms, and no one else can possibly be better judges of its quality and distinctness.

*

"BARE EARTH." — In a state of nature pure and simple bare earth is, comparatively speaking, unknown. The great desert itself is barren only where water is absent, and wherever moisture is even bare rocks soon become covered with vegetation. I was extremely interested in hearing an arctic explorer describe the lovely carpets of *Saxifraga oppositifolia*, of *Dryas octopetala* or *D. Drummondii*, of the sheets of *Papaver alpina*, and of other equally beautiful plants which spring into flower as if by magic at the commencement of the short, hot arctic summer time, and it was not the first time by many that I bethought me of the acres and acres of bare earth, earth needlessly bare, which we find in our gardens. The London market gardeners seem to recognise the old saw

Nature abhors, a vacuum, for they do keep the ground well covered; no sooner is one crop removed than another is planted, due compensation being made to the soil in the shape of manure. I also think the less bare earth we have in our flower gardens the better. By covering every bare spot of soil with good plants weeds have no chance; it is because useful and ornamental plants are too few and far between that weeds are so many and so troublesome in our gardens.

*

SUMMER RAIN.—After what has been a long dry time genial showers have come again to us on this 7th day of June, and they are welcomed alike by birds and many thirsty blossoms. A garden is ever most pleasant at Matin time, but on a warm showery morning this enjoyment is intensified, and so it is to-day when every leaf is dripping and there is perfume everywhere. The birds warble in the shimmering depths of young leaves, and the tall crimson-scarlet—or oriental—Poppies have their great black eyes filled with tears for very gladness that the rain has come to their thirsty rootlets and to their parched and dusty leaves. The rain to-day is so gentle that one is tempted to walk about in it, and yet how soon that steady drizzle wets one through. There is no splashing of earth over leaf and blossom as in autumnal rains, no washing away of soil from high places as when thunder-storms sweep over our gardens, but the rain of to-day is welcome for its very gentleness—it is of all things precious to the garden and to the gardener this soft rain of the rosy summer time.

*

THE DOUBLE WHITE ROCKET.—Not the true old English or pure white Rocket, but the more robust French kind, is just now very showy and fragrant withal in our gardens. It is easily cultivated, and its foot-long spikes, arranged with leaves of *Funkia Sieboldi* (Siebold's Plantain Lily), are most useful for large vases indoors, enduring for many days, and being deliciously fragrant at vesper time. It is worth growing in quantity everywhere, and growers of the Rocket as a florist's flower were ever mindful to take the branchlets off the main spike so as to obtain the main stem as stout and as strong as possible; but we here allow them their own sweet will, and so obtain many secondary spikes smaller, but not less useful for cutting than the large central stems. Our plan of culture is simple. After blooming, or before every clump is mulched with leaf-mould, which induces the old stem to send up a whorl of offsets or side shoots, and these are taken off and replanted as soon as they are well rooted into the leaf-mould around them. Treated in this way, we have always plenty of young plants, and these flower better and stronger than the old ones left undisturbed.

VERONICA.

Killing weeds by poison.—The Earl of Haddington had a compound labelled "poison," used on a portion of the carriage drive to his seat at Arderoe Hall, Tarporley, Cheshire, for the purpose of killing weeds. Shortly after, the herd of cattle grazing in the park showed symptoms of poisoning. A veterinary surgeon was immediately sent for, but, despite his skill, two valuable cows died.

Alexandra Park.—The Bill promoted by the owners of the ill-fated Alexandra Palace for giving them authority to turn the whole of their land, 150 acres in extent, into building sites has been withdrawn. Parliament, in 1866, sanctioned the making of certain railways to the palace on the express condition that the palace grounds should be used in perpetuity as a place for public resort and recreation. A year or two later the proprietors succeeded in obtaining from Parliament a release of this condition as regarded about 50 acres, and villa residences have been built over this area, on the faith that the adjoining grounds, about 150 acres in extent, would remain an open space in perpetuity. It is suggested that the land be purchased and dedicated as a public park by the Corporation of

London or the Metropolitan Board of Works. Nearly the whole area is outside the district of the latter body, so that the Corporation would be enabled to apply the metage on grain duty for the purposes of the purchase, while the amount of the purchase money should, of course, be calculated with reference to the restrictions imposed by Parliament on the use of the land.

TREES AND SHRUBS.

SELECT LAWN TREES.

TREES for a lawn may be divided into two classes, viz., those whose principal merit lies in the flowers, and those in which the blossoms play but a minor part. Under this latter head are included those with handsome foliage and elegant habit. Among

FLOWERING TREES the earliest to open are the several varieties of Almond (*Amygdalus communis*), which are generally grafted standard high, and soon form medium sized heads, and are beautiful when in flower either dotted singly on lawns, or occupying a prominent place in shrubbery borders. There are several varieties of Almond, but the most conspicuous is the deep rose-coloured form. Double-blossomed Peaches succeed the Almond, and afford a considerable range of colour, the blossoms being white, rose, red, and particoloured. They are also generally seen in the shape of standards. *Amelanchier vulgaris* is a low-growing, somewhat spreading tree at most only about 15 feet or 20 feet high, bearing pure white flowers, produced in such profusion as to cover the plant. This is the earliest flowering of the *Amelanchiers*, the American kinds being rather later in opening and larger growing, though equally desirable. Many of the *Pyruses* form handsome lawn trees; the Mountain Ash (*P. Aucuparia*) is pretty when in bloom, but much more so when laden with ripe coral-coloured fruit. The white Beam Tree (*P. Aria*) is more erect and formal in habit than the Mountain Ash; its blossoms are, however, much in the same way, though the leaves are quite different. The latter are large, ovate, and silvery underneath, and when stirred by wind are strikingly interesting. The Chinese *P. spectabilis* belongs to the same section as the Apple and Pear, and perhaps it is no exaggeration to say that when in bloom it surpasses both as regards beauty. It is a free, rather erect-growing kind, with large pink flowers, deep red in the bud state. The Garland *Pyrus* (*P. coronaria*) is an American form of the Crab, and valuable not only on account of the beauty of its large pinkish blossoms, but also from the fact that they are late in expanding. To these might be added many others; indeed, all the cultivated Apples and Pears form handsome isolated specimens when in flower, but the temptation afforded by their fruit when ripe often prevents their being planted for ornamental purposes. Amongst the different varieties of the Cherry (*Cerasus*) are the single and double, white and rose-coloured. The Bird Cherry (*Cerasus Padus*) now and then assumes the shape of a large bush, and at other times that of a small tree. It is remarkably handsome in spring when laden with racemes of pure white flowers, and scarcely less so in autumn, when the fruit is ripe, though birds then quickly destroy its beauty. Of *Prunus divaricata* there is a tree or large shrub some 15 feet or more in height on one of the lawns at Kew which every spring is very attractive. It somewhat resembles the Sloe both in growth and blossom. The lower branches of this particular plant rest on the ground, and when in flower it is clothed from base to summit with pure white blossoms. As seen at Kew it is certainly one of the best lawn trees which anyone could possess. Some of the Thorns also are well worth attention, the different varieties of the common Thorn (*Crataegus Oxyacantha*) being grand objects when in flower. We have single and double white, single and double pink, and bright crimson, the best of the latter being Paul's Crimson Thorn, which is very bright and effective. *Crataegus coccinea* (the Scarlet Thorn) is a vigorous growing tree, which flowers later than the common kind, and is handsome in

autumn when in fruit. The Cockspur (*C. Crus-galli*), or at least one of its vigorous varieties, such as *arbutifolia*, is also well adapted for a lawn. It has a bluntly pyramidal habit, leaves deep green, ovate, and very shiny. Besides the beauty of its foliage, this Thorn is valuable from the fact of its flowering very late in the season. Nearly allied to the Thorns is *Mespilus Smithi* or *grandiflora*, a tree about 20 feet high, with loose, irregular branches, somewhat like the common Thorn, but remarkable from the size of the pure white blossoms with which it is thickly studded in the end of May. The flowers, which are solitary, are as much as 1 inch or 1½ inches in diameter.

MAGNOLIAS form another beautiful class of lawn trees, the Yulan (*Magnolia conspicua*) opening its blossoms early in spring before the foliage expands, and when studded with its large white flowers it is a magnificent sight, and though at times liable to be cut by late frosts as a rule around London it opens its flowers satisfactorily. This *Magnolia* forms a bluntly conical shaped tree, 20 feet to 30 feet high, of very regular outline when grown clear of other subjects. The next in order of flowering is *M. Soulangeana*, rather looser in habit and less in stature than the preceding, from which it is said by some to be a seedling. Instead of the pure white blossoms of the Yulan, those of this variety are more or less tinged with purple, and expand about a fortnight later. Another of the early flowering section is *M. purpurea* or *obovata*, but it does not attain the dimensions of even a small tree, seldom exceeding 6 feet in height. The Cucumber Tree (*M. acuminata*) is regular in outline when young, but spreading when old. The leaves of this kind measure from 6 inches to 10 inches long; they are bright green and produced in abundance, but the greenish yellow blossoms are not very ornamental. It may, indeed, almost be said to depend wholly upon its foliage for effect; even in that case it is a handsome lawn tree. *M. auriculata* and *macrophylla* seldom do well, but where they succeed their very large leaves and handsome flowers render them noble trees. Contrary to the two last named species, another very large-leaved kind (*M. umbellata* or *tripetala*) succeeds almost anywhere, provided the soil be not too hot and dry. It is of free growth, openly pyramidal in habit, and about June when in flower is a grand sight. The leaves are from 1 foot to 1½ feet long, disposed in a ray-like manner around the branches, while the principal shoots are terminated by white open flowers 6 inches or 8 inches in diameter. For a damp spot *M. glauca* is well suited, as it thrives best under such conditions. It reaches a height of 10 feet or 12 feet, and is often shrub-like in habit, but at times assumes the shape of a small tree with irregular spreading branches, and during summer produces for a long time its white fragrant blossoms, each about 3 inches in diameter. The evergreen *M. grandiflora* is better adapted for lawns in the south and west of England than in colder districts where it is apt to be injured; an old tree of it on one of the lawns at Kew has stood many years, and occasionally flowers freely. The golden blossoms of

THE LABURNUM have no rival as regards colour, besides which Laburnums will thrive in almost any situation, and in an open spot form handsome trees. Another of the Leguminosae, and one seldom seen on lawns, is *Sophora japonica*. I have seen thriving specimens of this about 20 feet high clothed to the ground with branches, which about August become covered with creamy white blossoms. The Flowering Ash (*Fraxinus Ornus*) reaches a height of from 30 feet to 40 feet, but even when about half these heights and in a thriving condition it is a handsome tree, and one that does well in most soils. The flowers resemble greenish white plumes and are produced in great profusion. The red-flowered Chestnut (*Æsculus rubicunda*) makes a handsome isolated specimen. Besides the colour of the flowers the tree is less in size and the foliage darker than that of the common Horse Chestnut, but among large trees this latter is unsurpassed when in bloom. *Paulownia imperialis*, though its leaves are large and fine and

its panicles of Foxglove-like flowers pretty, has one great drawback, and that is during severe spring frosts the blooms perish while still in the bud state; when in full flower, however, it is very handsome. *Catalpa syriaca* bears a marked resemblance to the *Paulownia* when not in bloom, each being of open tree-like habit with stout, but comparatively few branches. The flowers of the *Catalpa*, however, more resemble those of the Horse Chestnut than the *Paulownia*, although on large branching panicles like those of the latter. The *Catalpa* flowers about July, and both it and the *Paulownia* like a good deep soil. The Snow-drop Tree (*Halesia tetraptera*) is a slender growing tree with horizontal branches, from the branchlets of which depend clusters of white Snowdrop-like flowers. The lightness of its appearance and the profusion with which, in the month of May, the blossoms are borne, stamp it as a distinct and ornamental tree. The Stag's-horn Sumach (*Rhus typhina*) often assumes the character of a small tree crowded with tortuous irregular branches. Its large pinnate leaves render it distinct in character, more particularly about the end of July when each shoot is terminated by a dense clustered spike of crimson-purple flowers. *Koeleria paniculata* is a low tree, in general character somewhat like a *Rhus*, but of more slender growth. It is especially valuable from the fact of its flowering towards the end of the summer when the bulk of flowering trees is out of bloom. Among

THE MAPLES (*Acer*) we have a great variety of trees with fine foliage. Amongst them may be noted the striped-barked Maple (*A. striatum* or *pen-sylvanicum*), a tree 20 feet or so in height, with three-lobed leaves and beautifully striped bark. The Silver-leaved Maple (*Acer dasycarpum*), a large and rapid growing tree with spreading branches and finely lobed foliage, silvery white beneath, is also very ornamental. Of this there are several varieties of American origin, among them being *heterophyllum*, *laciniatum*, and *laciniatum Weiri*, which I have only seen in a small state, and as such they are beautiful. The red Maple (*A. rubrum*) is very handsome in early spring before the expansion of the leaves, as the clusters of small crimson flowers are produced in such profusion as to impart quite a feature to the tree. The young leaves are also bright in colour and the decaying foliage in autumn becomes tinged with red. This tree is too large for most lawns, and is better adapted for the park or pleasure-grounds. *Acer platanoides* *Schwiedleri* is a variety of the Norway Maple, and, like it, a vigorous growing tree, but instead of the normal green foliage the leaves of this kind are crimson when expanding, but become greener as the season advances. The Japanese Maples are beautiful, but as at present seen in gardens merely shrubs. I have, however, a plant of *A. polymorphum atropurpureum* now growing away freely, and the admiration of all who see it. The common Birch (*Betula alba*) is very distinct from other trees, and forms a handsome isolated specimen when some 30 feet or 40 feet high. Among varieties of it are the cut-leaved, the purple-leaved, and a couple of weeping kinds known as *pendula elegans* and *pendula Youngi*, both of which are quite distinct from each other. Of the common Beech (*Fagus sylvatica*) there are also cut-leaved, weeping, and purple-leaved varieties, the last of which varies greatly in colour, but when a good form is obtained and judiciously planted, it is a very effective tree. *Salisburia adiantifolia* is distinct in foliage, habit, and general appearance from most trees commonly planted, and does not soon outgrow its allotted space. Several of the Elms are very pretty, especially some of the weeping kinds, and *Ulmus viminalis variegata* I think the most perfectly variegated tree that has yet come under my observation, except it be the variegated *Negundo*. *Ailantus glandulosa* is a fine vigorous pinnate-leaved tree quickly attaining a height of 20 feet, and not particular as to soil. It is remarkably handsome when studded with capsules, which in general appearance resemble the keys of the Ash, but are larger in size. Their colour is a bright brownish crimson, which, especially when the sun

shines, renders them very attractive, but unfortunately the tree is not often seen in a fruiting condition. The Hop Hornbeam (*Ostrya vulgaris*) in appearance resembles the common Hornbeam, except that it is more symmetrical in growth and differs as regards the female catkins. It forms a spreading, bluntly conical head, which about May is thickly studded with pendulous greenish male catkins, but towards the end of the summer the fruits become very prominent. They resemble very much the catkins of the Hop, and as they are produced in great profusion impart a distinct character to the tree. Near the old rockwork at Kew a large plant of this kind is every year very conspicuous about the months of August and September. In damp spots some of the Willows make handsome specimens, notably the common Weeping Willow (*Salix babylonica*) and the golden-barked *S. vitellina*. The cut-leaved Alder also does well under similar conditions. Between trees and shrubs it is scarcely possible to draw a hard and fast line, so that under the head of trees I may have included a few that would be by some considered shrubs, and have kept for a future time a few shrubs that might perhaps be regarded by some as trees. ALPHA.

FLOWERING TREES AT BYFLEET.

VERY prominent amongst flowering trees in Mr. Stevens' garden are Paul's Crimson Thorn and the snowy *Mespilus*. The first named is now well known, though scarcely so freely used as it might or ought to be, neither is the *Mespilus* so frequently met with as one might expect considering its vigour, hardiness, and extremely ornamental character. These two trees should be grown wherever space can be found for them. *Spiræa ulmifolia* is a neat, compact habit, but tolerably vigorous growing species. It clothes itself with foliage from the ground upwards, and the flowers, which are white, are numerous produced; it is an attractive kind. *Weigela Abel Carrière* is a fine variety of this useful flowering shrub, the flowers being very rich in colour and so closely set on the stems as to render it very effective. Lilacs, of which Mr. Stevens has a large collection, have by no means bloomed well this year—a common complaint, I find. Especially noteworthy amongst them are a pale-coloured variety with very large trusses of bloom called *unguis* and a very dark-flowered variety named *Josikæa*. The foliage of this is so curious and distinct that one would hardly take it for a Lilac when not in bloom. *Andromeda Catesbei* is a free-flowering, rather graceful growing shrub, and *Daphne Fioniana* is a neat-habited species, the flowers, though small, being as fragrant as could be desired. These are very recommendable for small gardens, and suitable for the foremost rank in shrubberies generally. On the rockwork *Onosma tauricum* is doing as well as could be wished, its long clear yellow flowers rendering it very effective. By the way, how deliciously fragrant the flowers of this plant are; it ought to be good for bees. It would probably prove useful for poor sandy soils, dry banks, and the like situations. *Cheiranthus Marshalli* and *ochroleuca* are apparently best at home on rockwork; they are of the brightest of spring flowers. Equalling these for effectiveness, but in a different way, is *Saponaria ocymoides*, a large specimen of which smothered with bloom is a most cheerful object; whilst not inferior, indeed probably more showy, are the dwarf *Phlox*, of which *setacea atropurpurea* may be singled out for unusual beauty. The compact habit of profuse flowering *Cytisus purpureus* shows itself off well on a rockery, and one scarcely knows whether to admire it most thus placed or in the form of a standard. It is so distinct and pretty as to merit a place anywhere. A word of praise should be accorded the little *Mentha Requeini*; covering with a dense cushion of foliage a square yard of soil and studded with its small purplish flowers, it presents a very neat and attractive aspect.

J. C. B.

Eucalyptus coccifera.—During the past three years several of your readers have applied

to me for blooms of this *Eucalyptus*, growing in the American gardens here. The severity of the winters of the past few years has so destroyed the bloom buds, that I have not been able to favour them with any blooms. This year, however, they have escaped, and though the buds were very much advanced in March, when we experienced 14° of frost on several consecutive nights, with bitter east winds, yet they have escaped, and next week the tree will be a mass of bloom. I shall, therefore, be pleased to forward specimens to applicants if they will forward me their addresses again.—D. C. POWELL, *Ponderham Castle, Exeter*. [This tree, a fine one, measuring nearly 60 feet in height, and with a stem upwards of 7 feet in circumference, was noticed in THE GARDEN, Dec. 25, 1880, p. 650.]

GARDEN FLORA.

PLATE CCCXCII.

CALLICARPA PURPUREA.

SEEING some remarkably fine examples of this East Indian shrub in Messrs. Veitch's nursery, Chelsea, last autumn, we were much struck with its elegant growth and the rich colouring of the myriads of berries which hung in dense clusters the whole length of the slender shoots, which were several feet in length, and drooped gracefully on all sides of the plant. These plants were very effective in the stove, being quite different in aspect from all their associates. The *Callicarpa* is an old plant, but we are convinced that it is not half known enough; therefore, with the view of making it more popular, we give the annexed coloured plate of it, which represents some of the best shoots on Messrs. Veitch's plants. In the Birmingham Botanic Garden this plant is grown to perfection by Mr. Latham—better, in fact, than we have ever seen it elsewhere. Some specimens of it which we saw in one of the stoves there some time ago were singularly beautiful and the admiration of all who saw them. At our request Mr. Latham has kindly furnished us with the following remarks respecting this shrub: "It was introduced from the East Indies about sixty years ago. As a decorative plant for a cool stove or warm conservatory I know of none more useful. Its branches grow some 3 feet to 4 feet in length, and from every axil of its bright green leaves are produced clusters of purple berries. It grows freely from seeds or cuttings. Started early in the year and grown on without a check, good fruiting plants may be had by the autumn. They should be potted in good loam with a little leaf-soil or manure, but must not be over-potted. Manure water may be given liberally when the pots get full of roots. Our plants are now about four years old from cuttings, and are grown as standards with stems about 3 feet 6 inches in height. These plants are cut back every year in February, leaving about 4 inches of the previous year's growth. They soon start afresh and form, as I have said, branching shoots 4 feet and upwards in length covered with berries. The leaves of this plant being rough and tender, it is necessary to keep them clear of dust and insect pests from the very commencement of growth, for once the latter obtain a lodgment it is almost impossible to clean the plants without damaging them."

5005.—**Destroying woodlice.**—These pests are easily destroyed by paying a visit to their haunts at dusk. They are easily caught and killed on a wall. Why not stop the holes up in early spring when the trees can be detached from the wall?—W. P. R.

SEASONABLE WORK.

INDOOR PLANTS.

STATICES.—Blue flowers are comparatively scarce amongst greenhouse plants, particularly such as are of a lasting character. The different species of *Statice* supply various shades of this colour; the flowers are most enduring, and the plants when healthy keep on producing a succession so long as they are in active growth, added to which the plants last for a number of years when well treated; but there are several matters connected with their cultivation in which they differ somewhat from the generality of other subjects. To keep the leaves in a healthy condition they must not be exposed to the full force of the sun from the time it gains considerable power until it wanes in autumn; otherwise, they assume an unhealthy, bleached appearance, and do not attain nearly their full size. The plants should not be kept lower than from 40° to 45° during winter, or the growth becomes stunted. They are free rooters, and require more pot room than many things which attain larger size. Good yellow loam is the best soil in which to grow them, and when in full growth during spring and summer they are much assisted by frequent applications of manure water. They require no training for ordinary uses. *S. profusa*, *S. Butcheri*, *S. imbricata*, *S. brassiceifolia*, and *Holfordi* are all deserving of cultivation. Anyone who will keep up a stock of these need not be without their flowers for any length of time. If cut whilst fresh and dried quickly, they will retain their colour and form for a length of time. Cuttings made of moderate-sized shoots kept in a medium heat and confined under a bell-glass strike freely. The present is a good time to put them in.

PLEROMA ELEGANS.—This bears lovely, large, violet-coloured blossoms, unapproached by any flower of a like colour. It is easily managed, requiring only to be turned out-of-doors from about the middle of July to the end of August, so as to ripen its wood. It attains a considerable size, but is best for general use when in a small or medium state; it blooms freely, and will flower in 8-inch or 9-inch pots. It succeeds in peat or loam, but I prefer the latter. All that is required is to see that the shoots are frequently stopped from the time the cuttings are well rooted until the plants have attained a bushy condition; by this means half-a-dozen sticks will give all the support which a good-sized plant requires. Cuttings made from the young shoots as soon after this time as the wood has attained a little solidity will strike in three weeks. It blooms from the young growth in July, August, or September, according to the way in which it is treated as regards warmth in spring. Half-a-dozen of its half open flowers well placed in a bouquet give an effect that nothing else I have ever seen used does. It likes a little shade in summer, or its leaves turn red, and do not last their full time.

CASSIA CORYMBOSA.—Although this is seen to the best advantage when planted out and covering a wall such as the back of a greenhouse or conservatory, yet, as generally grown in a pot, it looks well and yields a succession of its bright yellow flowers which come in during the summer and autumn. If kept repeatedly stopped, so as to induce the formation of plenty of shoots near the base, it will need no sticks. Cuttings of it should be put in about this time if they can be had 3 inches or 4 inches long; they ought to be taken off with a heel and treated in the usual way.

GENERAL STOVE STOCK.—More air should now be given to the general collection of stove plants than hitherto, but in doing this care ought to be taken never even at this season, whilst the growth of most plants is yet soft and tender, to carry this so far as to over-dry the atmosphere, otherwise the foliage gets stunted, and the attacks of red spider are almost certain to follow. Keep all but the exceptionally few things that do not like too light a position as well up to the glass as circumstances will permit. Where this is done, the

syringe may be used freely without danger of the soil within the pots getting too wet; mere sprinklings on the top of the leaves are useless, as far as keeping down insects is concerned. Instinct teaches most of them to keep to the underside of the foliage; consequently, unless the water reaches well the spots where they congregate, they are not affected by it. Close early whilst there is plenty of sun warmth; this is much preferable to fire-heat. Now that the stock of bedding plants will be cleared out from pits, where if necessary a little fire-heat can be given, it will be well to thin out such of the plants from stoves as can be accommodated in the pits during summer. This will be of immense benefit to the whole, as, wherever crowding exists, good cultivation is out of the question. Attend to the timely stopping of all young stock required to assume a bushy form, not that it is desirable to give plants in general a too formal, dumpy appearance, but the absence of early and sufficient pinching back of the leading shoots necessitates the after use of more sticks and ties to support many plants than should be employed.

CORONILLAS AND VERONICAS.—*C. glauca* is a pretty summer-blooming floriferous plant. It is not a large grower, and on that account may be used plentifully. Small examples of it in 6-inch or 7-inch pots bloom freely. It requires ordinary greenhouse treatment. When done flowering it should be cut back freely. Which ever way the autumn and winter-flowering supplies of *Veronicas* are managed—in pots or planted out for subsequent lifting—they must be encouraged to make bushy, stout growth. To keep them compact it is well to again pinch out the points of the leading shoots, but with the autumn-blooming kinds, such as *Andersoni*, the next stopping is the last they should receive.

STOVE TWINING AND CLIMBING PLANTS, grown as specimens for removal to conservatories or greenhouses when in flower later on, will require frequent attention as to keeping the shoots trained to the sticks or wire supports, but for home decoration, where the plants will not necessarily be subjected to any knocking about such as in conveyance to an exhibition, there is no necessity for their being tied so as to have any approach to formality. Where to be so used all that is required is a few sticks with the shoots loosely wound round them. Stove plants that can with advantage be so used in cooler houses during July and August may include *Allamandas*, *Bougainvillea glabra*, *Dipladenias*, *Clerodendrons*, *Ixoras*, *Rondeletias*, *Vincas*, *Tabernaemontanas*, and others of like character which are often kept wholly in stoves at a time when they would be most useful in conservatories to help to maintain a display of bloom, but to enable such subjects as above named to preserve their flowers in fair condition, and not to receive injury by being thus submitted to cooler treatment they must have been so treated previously as will ensure their bearing this. It is not enough that for two or three weeks before being taken out of the stove they should have more air and less shade, which will effect the necessary conditions of keeping the atmosphere drier, but they should all along, whilst the growth was progressing, have been kept with their heads close up to the glass in a light house; without this no amount of after hardening that they can have will enable them to stand the lower temperature and preserve their flowers so as to have a good appearance. It is the want of this gradual preparation—this exposure to light through the early stages of the season's growth—that prevents the possibility of many stove plants being used in the way here indicated, thereby reducing much of their usefulness. We have found that the check thus given for a time during the warmest part of the summer was the best means of giving many things a rest, and much to be preferred to the severe root-drying process often practised.

BEGONIA FUCHSIODES.—This plant, not now so much grown as it used to be, is, nevertheless, one of the best of all the *Begonias*, and where well managed gives a profusion of flowers for a

lengthened period either when grown in pots or planted out. Where trained to a pillar or rafter, and it can be accommodated with intermediate warmth, it is one of the most effective plants in cultivation, with the still further recommendation that its flowers are well adapted for cutting. Examples required for flowering in autumn should now be exposed to all the light possible, giving no more shade than is necessary for such other things as may happen to be grown in the same house. If treated in a way to give solidity to its succulent shoots it will bloom in either a large or small state; moderate sized plants, such as may be grown in 9-inch or 10-inch pots, are generally the most useful. Small ones that have been hitherto kept in 6-inch or 7-inch pots if now moved into others two or three sizes larger will make nice specimens before autumn.

FLOWER GARDEN.

HUMEA ELEGANS.—When well grown, this greenhouse biennial ranks amongst the foremost of plants noted for handsome foliage and elegant feathery inflorescence. It is invaluable for the centres of large vases in summer, and also for the sub-tropical garden, either for putting out in beds or for plunging in the pots in the turf, or near the margins of walks in order that its rich fragrance may the more frequently be enjoyed. It should be raised from seeds sown on a hotbed in May, and the seedlings should be pricked off as soon as they can be handled and potted on before the roots get matted together. They should be grown in the open air, where they should be treated like *Chrysanthemums*, and be housed about the beginning of October and afforded ordinary greenhouse cultivation. By the new year they will be ready for their final shift into large pots, and about the middle of May they may either be placed in position in the open air or be planted out in beds. They flower best when plunged in the beds in the pots, but need more attention as to watering than they do when turned out.

GENERAL WORK.—Notwithstanding the absence of rain, the advancing season bespeaks how important it is that planting should be finished as quickly as possible. This done, the next most important item is the well-doing of the plants; to this end and also to the earlier effectiveness of the same, mulch or keep the ground loosened with a small hoe, or, where the plants are very close together, with a pointed stick. Carpet beds we prefer to mulch with Cocoa-nut fibre; *Violas*, *Calceolarias*, and the like with manure. Sub-tropical plants are indirectly mulched by pegging down the groundwork plants as soon as practicable. Trivial and unnecessary as these operations may appear, they are important factors to real and speedy success. Staking, tying, and keeping the flowers picked off *Cannas*, *Castor-oils*, &c., to aid their more rapid growth are the only other immediate requirements needed by sub-tropical plants. Ordinary kinds of bedding plants should be frequently gone over in order to remove bad foliage and flowers. *Pansies*, *Violas*, and *Calceolarias* are quickly exhausted, and cut a sorry figure in dry weather if the old flowers and seed vessels are not removed frequently. Peg down or pinch as may be requisite all groundwork plants; high keeping and the working out of every line or panel true to pattern is of the utmost importance in carpet bedding, and those who do not intend to take this pains ought not to attempt it. Now is a good time to make another sowing of *bienials* and *perennials*, such as *Brompton Stocks*, *Sweet Williams*, *Wallflowers*, *Delphiniums*, *Foxgloves*, *Aquilegias*, *Canterbury Bells*; in fact, seeds of these may be sown now in the open borders with a fair prospect of success, the only real danger of any mishap occurring to the seedlings being from attacks of slugs, which should be prevented by using soot or lime liberally about the seed beds. Keep all herbaceous plants well up to supports; our rule is to place sticks to each plant—in size as may be required—at the beginning of the season, and look over the plants once a week after-

wards, in order to tie or remove suckers, weeds, &c. Finish the clipping of Box edgings and evergreen hedges, also the cutting back of flowering shrubs and the new growths of those that are encroaching on walks. Other pressing routine duties may be summed up in three words—mow, sweep, and weed.

FRUIT.

PINES.—Plants now swelling off fruit will require more water of a stimulating nature than has hitherto been given to them; they will also derive great benefit from diluted liquid carefully syringed over the surface of the bed and into the axils of the lower leaves after the house is closed for the day. Keep the atmosphere moist by damping the walls and all available spaces and by filling the evaporating pans with liquid from the manure tank, but avoid heavy overhead syringing, as it increases the size of the crowns and encourages the growth of gills and suckers. Let the temperature range from 70° at night to 85° by day. Give a little air at 76°, gradually increase it as the sun gains power, and close in time for the house to run up to 90° with solar heat. Remove ripe fruit to a cool vinery in which the Grapes are ripe and withhold water, or cut and suspend them in the Grape room until wanted for use.

SUCCESSIONS.—The best plants that were shifted into fruiting pots early in March should now be filling the soil with roots, and the bottom-heat being satisfactory, liberal supplies of liquid or guano water will be needful at every watering. Keep them well supplied with atmospheric moisture by syringing the paths, walls, and surface of the bed, and slightly dew them overhead after closing on fine days. If the plants are plunged in Oak leaves and there is a sign of the heat declining this is a favourable time for rearranging and giving them more room if required, but it will not be well to disturb or do more than level the surface of the bed, and place a few fresh fermenting leaves on the top and between the pots as the work proceeds, as the slightest disturbance at this season sometimes starts fresh fermentation, and a violent heat just now might throw many of them into fruit. Avoid strong fire heat and dispense with it altogether when 60° to 65° can be maintained at night without it. Give air early, gradually raise the temperature to 80°, and run up a few degrees after closing.

FIGS.—Trees in the second house now ripening or swelling off the first crop of fruit will require an abundant supply of stimulating liquid, and good syringing where water can be applied without wetting the fruit. Turn the foliage aside where the ripening fruit is too much shaded from sun and light, and maintain a gentle circulation in the hot-water pipes to keep the house up to 60° or 65° at night, and to admit of a plentiful circulation of air by day, without which Figs of high quality cannot be expected. If spider or scale attack the leaves, and a flush of ripening fruit puts a stop to syringing, sponge the parts affected with soap water to keep these pests in check until syringing can be resumed.

EARLY HOUSES from which all the fruit has been gathered will be the better for a good washing with the garden engine, and the mulching may be replenished with fresh manure, to be washed down to the roots with liberal supplies of tepid liquid or guano water. As the second crop of fruit does not always come so fine as the first, thinning with a liberal hand will be advisable, but instead of taking off all the smallest, it will be well to take off and leave some of all sizes, to prolong the supply when the trees again begin to produce ripe fruit. Although fire-heat will still be necessary at times, it must be used in moderation, particularly at night, when comparative rest will benefit the trees, and early closing with solar heat and moisture will redeem the time lost without distressing them. When young trees in pots intended for forcing have made their second growth, stopping must be discontinued and stimulating food must be withheld, in order to secure firm,

short-jointed wood, which will be thoroughly ripe by the autumn.

MELONS.—About this time a number of pits and frames will be set at liberty by the clearance of forced vegetables and the more tender bedding plants. To make the best use of these, a good stock of the leading kinds of free-setting Melons, including Golden Gem and Victory of Bath, should be ready for turning out in strong, but not over rich loam, placed in ridges some 18 inches from the glass. As many of the preceding occupants leave a colony of insects behind, the frames and lights should be well cleansed with boiling water, and in order to give the plants a start, a trench may be taken out along the centre of the old bed, and filled in with fermenting leaves or stable manure, which should be made very firm before the soil is introduced. A good external lining along the front will also assist the plants through the early stages of growth. Early crops now swelling or ripening off will well repay steady attention to linings and covering up with mats at night. Reduce the supply of water and atmospheric moisture when the fruit begins to change colour. Ventilate more freely on bright days, and insure flavour by full exposure to sun and air. The cultivation of Melons in houses after this time is a very simple matter, the main points being a bottom-heat of 84° to 90°, plenty of air on fine days to secure dark green, sturdy foliage, an abundance of water to the roots, and a good syringing to keep them free from insects.

PEACHES.—When all the Peaches have been gathered from the early houses the trees must be well washed with the syringe to free them from all kinds of insects, and the borders must be well mulched and watered with diluted liquid or clear water, according to the strength of the young growths and the quantity of fruit the trees have brought to maturity. As next year's crop depends upon a clean, healthy, well-ripened growth, all shoots rendered useless by the removal of the fruit should now be cut away to admit of the free admission of light and air, gross shoots should be stopped or removed, and ventilation should be of the most liberal character.

SUCCESSION HOUSES, in which fruit is now taking the last swelling, will require copious supplies of water, good syringing twice a day, with a temperature ranging from 60° at night to 80° by day. Elevate all pendent fruit and keep the foliage turned aside where colour is an object. Pinch the points out of the shoots intended for removal after the fruit is gathered, and secure flavour by giving an abundance of air. Where the brilliant weather we had in May has hastened late houses, the ventilators may be kept constantly open; frequent damping with cold water will keep the atmosphere cool, and an unrestricted growth of the young wood will help to retard the stoning and swelling of the fruit.

HARDY FRUIT.—Apples everywhere promise to be a good crop, but in places sadly blighted. Pears are not so badly affected in that way, and in many places the fruit is plentiful, clean and fine. Peaches and Nectarines are abundant, and the trees being clean, healthy, and vigorous, good crops of these may now be considered safe. Apricots are thin in most places. If any of the trees remain unmulched, no time should be lost in getting some kind of covering placed on the borders. Where they are heavily cropped good stable manure is undoubtedly the best material that can be used; but, lacking this, anything capable of checking evaporation will have a beneficial effect. On all light non-calcareous soils stone fruit trees derive great benefit from liberal dressings of old lime rubble, which, if laid on the borders in the spring, forms no mean mulching in itself, as it keeps in moisture better than many imagine, while the properties it contains supply an important want often severely felt by the trees at the time of stoning. Before the laying-in of the shoots of Peaches is commenced, a thoroughly experienced person should go over the trees to complete the disbudding and thinning, and at the same time to pinch the points out of young shoots which are likely to become too

strong, to the detriment of weaker growths, or where they are likely to detract from the size of the fruit, and on no account should a single shoot be laid in unless it is wanted to carry fruit next year, or to complete the furnishing of the tree. Pears, Plums, and Cherries may now have all the strongest breast-wood cut away to the third or fourth eye, but the system of leaving all the growth to be cut away at once is not a good one. It is much better to commence earlier and carry on a regular system of pinching. In wooded districts the early kinds of sweet Cherries must be netted as soon as they begin to ripen to protect them from birds. Strawberries, too, apparently a most abundant crop, will require attention. There are numerous modes of treatment recommended for the production and protection of this valuable fruit. The most important points at the present time are copious supplies of water, a ground covering of straw or litter to keep in moisture, and protection from birds and slugs. Where the latter are numerous, or, indeed, where they do not exist—quantity and quality being the first consideration—the most economical plan is to place four short sticks to every old stool and two to younger plants, and form a support for the fruit by running a piece of matting or twine round them some 9 inches from the ground. All the trusses can then be turned outwards to the influence of sun and air. Slugs are isolated, and the fruit dries quickly in showery weather.

ORCHIDS.

EAST INDIA HOUSE.—There are certain varieties and species of *Cypripedium* that succeed best in this house; indeed, some that do well in a cooler house succeed quite as well here and grow more freely. Now is a good time to attend to repotting them. Some succeed best in small pots, and amongst these may be named *C. barbatum* and its varieties, *C. Veitchii*, *C. Lawrenceanum*, and others of that type. *C. Lowii*, *C. Stonei*, *C. Dominii*, and others of that class succeed perfectly well in large pots in the form of good specimens. These should also be potted if they have done flowering, taking care to remove any decayed, useless compost from the roots. We find at this season that it is a good plan to syringe these plants overhead twice daily in hot weather, an operation which does them good and has also the effect of keeping them free from red spider and thrips. The different species of *Angraecum* should now be pushed on in a high temperature, with plenty of moisture; they are now pushing out fresh roots and are growing freely. A very small species of thrips does much damage to the plants by preying on the young leaves just pushing out from the centre of the plants. It is not observed until the effects of its presence is seen on the leaves. Tobacco water kills it. *Grammatophyllum Ellisii*, another Madagascar plant, well worthy of culture, does best in the warmest house. It generally flowers in August, and should now be pushing its flower-spikes from the base of the last growth. It does best near the glass in a pan or basket. The temperature of the house should now be 70° as a minimum.

CATTLEYA HOUSE.—Many of the Cattleyas are now starting into growth, and some have even made considerable progress. Where plants of *C. Mossii* or *C. Mendellii* have flowered freely, they are not likely to produce more than one growth from each lead, and that is quite sufficient in the case of old-established plants. Plants done flowering and starting to grow ought to have a rather higher temperature, say 65° at night, and a moist atmosphere. We keep our house rather dry at present, with a temperature of about 60°, as we want to keep some Cattleyas and *Oncidium*s in bloom as long as possible. *O. crispum*, a good and distinct species, is now in flower in this house. It seems to do well potted and treated similar to Cattleyas, but we allow the roots to grow over the sides of the pots. *Odontoglossum citrosimum* is over, and the bulbs, by their slightly shrivelled condition, show the strain to which they have been subjected during the flowering period; they will soon plump up in a higher and moister atmosphere, aided by a

good supply of water to the roots. The young growths are now pushing on rapidly. *Oncidium Marshallianum*, certainly one of the most beautiful of the yellow-flowered species, is also starting into growth, and the young roots are pushing over and down the sides of the pots. Look over them every night for slugs and snails, and also trap these pests with bran or Cabbage leaves. Allow the plants to have all the light it is possible to give them, but do not expose them to the direct rays of the sun.

COOL HOUSE.—Those who have a number of plants of *Oncidium macranthum* need not be without its flowers for the next two months at least. This is one of the most distinct and best of *Oncidiums*, and valuable because it succeeds well in the cool house. It has one fault, a serious one, viz., the flowers take so many months to develop, that the plants are well nigh exhausted before they open. Two seasons' flowering sometimes gives the plants a serious check; our best plant flowered two years in succession, and looked all the worse for it. This year it has not produced any flower-spikes, but is taking a rest, we hope, to produce better spikes next year. This species requires treatment similar to that needed by most other cool house species. If any plants require repotting, this can be done when they start into growth after the flowering period is over. The weather has not been very warm as yet, but if it should set in close and very hot, this house will require extra attention, in order to prevent the plants from being injured by the heat. Give plenty of ventilation night and day, and use thick shading, raised a foot or so above the glass, so that a circulation of air may be kept up between the glass and the shading.

KITCHEN GARDEN.

We are just now planting in their permanent places Brussels Sprouts, the previous crop being spring Cabbage and Lettuce. Brussels Sprouts being strong feeders, we treat them to a good manuring and a deep digging. Few things are so profitable, scarcely any so hardy, as Brussels Sprouts; therefore, they deserve all we can do for them. Our first lot of Celery is already out and in the trenches, and the bulk of our crop will be out in a few days. Our favourite varieties are Carter's Incomparable Dwarf and another dwarf white called Hastings' White Celery. We also have a few rows of Major Clarke's, which grows to a large size, and is most useful on special occasions. Among the best varieties of Peas to sow at this season is William I. and Unique, both of the green marrow type, and not so subject to that fatal disease, mildew, as many of the strong growing varieties. Parsnips, Carrots, Beet, and Onions will now require thinning, hoeing, and cleaning. We find the smaller Onions keep better than giants, and are better liked. Late Potatoes should be cleaned and moulded up at once. Sow at once a good bed of Parsley for spring use. We intend next week to begin planting in the quarters Veitch's Giant Autumn Protecting and Walcheren Broccoli. Speaking of Broccoli, we may add that Cattell's Eclipse met within a week the hand-light Cauliflowers. Slugs this season are plentiful, therefore soot and lime must be freely used. We sow them broadcast over any kind of seeds appearing above ground. Soil dried to dust is also useful for sowing on small plants; these miniature vermin do not at all relish anything gritty. Sow now Coleworts, Early York Cabbages, and a few Lettuces, but defer sowing Endive until the first week in next month; if sown earlier than that it generally runs to seed. Scarlet Runner Beans and late Peas must at once be staked.

Hardiness of Pansies.—I have been very much interested in the notes on the hardiness of Pansies. I have a few that I raised last year from a packet of mixed seed. The plants were left in the ground all winter, and had no protection whatever. Not only did they do well, but in spite of the severe weather, one or two were in flower in

February. They are now one mass of bloom, and will, I expect, continue so for some time. To keep Pansies in full flower, I find it by far the best plan never to allow the flowers to seed, but the moment the fresh beauty of the flower fades to pick it off. The plant is not so much exhausted in this way, and so it has a far greater strength within it to continue flowering, and so adds to the beauty of the garden. The trouble is really very little, and the results far greater than one would imagine. I neglected last year four plants, and allowed the seeds to form. The flowers became very poor and insignificant in size, and gradually died away altogether, whilst long after that the other plants were in full vigour and flower.—H. F. M.

GARDEN DESTROYERS.

REMARKS ON INJURIOUS INSECTS.

SOME of the readers of *THE GARDEN* may be glad of a few short remarks as to the best means of destroying various insects which are now making their very unwelcome presence felt in our gardens. Among those which are the greatest nuisance are

THE CATERPILLARS of certain small moths, which attack the foliage and flower buds of Roses. When standards and bush Roses are attacked they may be destroyed by pinching the leaves they are ensconced in, making sure that the enemy does not drop out of the leaf before the pinch is administered, or by cutting off the leaves or buds and allowing them to fall into a basket or other receptacle. Climbing Roses are more difficult to reach, but a pair of scissors on a handle, similar to those used for gathering Grapes, might have a small basket or tin box fitted to it so that when the leaves or buds were cut off the caterpillars fell out they would be caught. These caterpillars curl up and fasten the leaves together in such a manner that no insecticide will reach them. After pruning the trees, the shoots cut off should always be burnt, as they may have eggs on them.

THE GREEN FLY is a no less troublesome pest, and may be best dealt with by using a wash of some kind, which should be applied as soon as any of these insects are noticed on the Roses, for the green fly increase and multiply with such extraordinary rapidity that if the operation is delayed for a few days the trouble of cleaning the plants will be very greatly increased. The wash may be composed of $1\frac{1}{2}$ lbs. of soft soap, 1 quart of Tobacco water, and 3 gallons of water, or 4 oz. of Quassia chips, boiled for ten minutes in a gallon of water; when the chips are strained off add 2 oz. of soft soap, or 2 lbs. of washing soda, 1 oz. of bitter Aloes, and 1 gallon of water. The affected shoots may be either dipped in or syringed with these mixtures. An hour or so afterwards the plants should be well syringed with clean water. Fruit trees suffer from the attacks of various

MAGGOTS and caterpillars, which destroy the foliage and fruit. Those which destroy the former are the commonest. Some kinds may be shaken from the branches; others must be picked off by hand, or the leaves on which they are feeding gathered. If the caterpillars do not roll up the leaves, a good syringing with one of the washes recommended for green fly would be very useful. The fruit should be examined if possible from time to time, and any Apples which have a black or reddish-brown spot on them, indicating the entrance to the gallery formed by the grub, should be at once destroyed. All windfalls should be treated in the same manner, and if we cannot save our fruit we can in this way kill the grub, and so help to lessen the numbers of the next brood of moths.

GOOSEBERRY CATERPILLARS are of two kinds; one becomes a moth, commonly known as the magpie moth; the other, which is the commonest and most destructive, is not a true caterpillar, but the grub of the Gooseberry sawfly. Both kinds may be destroyed by the same means. When quite young the bushes may be freed from them by a

good syringing with 1 lb. of salt dissolved in 1 gallon of water. Dusting the bushes when the leaves are wet with powdered white hellebore 1 lb., and whitening 6 lb., or white hellebore powder 1 oz., and powdered alum 2 oz., well mixed in a small quantity of water, and then added to 1 gallon of water, are very effectual remedies; but as white hellebore is a violent poison, care must be taken in using it, and seeing that the fruit is thoroughly washed afterwards; 1 oz. of powdered alum in 1 gallon of water is said to be very deadly to the grubs, and is perfectly harmless to the human species. Sprinkling the bushes with anything dry and dusty when the leaves are wet is very useful. Road dust, powdered sulphur, or coarse flour, have all been found very efficacious in clearing bushes.

THE AMERICAN BLIGHT should never be allowed to establish itself on Apple trees, as it has been in some places, for it is then very difficult to eradicate it. As soon as any are noticed on a tree, the part infested should be well scrubbed with a hard brush, and one of the following mixtures: 1 pint of ammoniacal liquor and 2 parts of water; Tobacco water (quarter pound of Tobacco soaked in 1 gallon of water; a wineglassful of petroleum oil to 1 gallon of water, add a little soft soap to make the liquids mix better, or common train or fish oil. Brushing the insects with a small brush dipped in turpentine or spirits of wine kills them at once.

LEATHER JACKETS, the grubs of the daddy-longlegs or crane fly, appear to be numerous and destructive this year; they live on the roots of Grasses and various other plants, causing them to wither and die. They may be caught by burying, about an inch from the surface near the roots of plants, small pieces of Potatoes, Turnips, &c., with a small stick or skewer attached to them to show where they are; they should be examined every morning, and any grubs found sticking to them destroyed. Wireworm may be trapped in the same manner; these grubs often come to the surface at night, and may then be killed by rolling the ground. Trenches 6 inches wide and with upright sides the same height are very useful for catching the grubs; in their nocturnal rambles they fall into these pitfalls and cannot escape. When plants wither and fade without any apparent reason, an examination should always be made of the earth round their roots, when grubs or caterpillars will generally be found attacking them.

THE ONION FLY is a great pest in many places. Some persons have found that by keeping the roots well earthed up so that the fly cannot get at them to lay their eggs, is a very sure preventive. In thinning the crop great care should be taken to disturb the soil as little as possible for the same reason; sowing sand which has been soaked in petroleum over the beds, or watering them with 1 pint of petroleum mixed with 2 gallons of water, has been found very useful in keeping the flies away. When once an Onion is infested, there is nothing to be done but to remove it carefully and burn it; this is best done by digging it up with a trowel, for if any of the grubs are left in the ground or are allowed to drop out of the bulb, they will probably find their way to other roots. If this method is properly carried out the next brood of flies will be very much diminished in numbers.

THE CARROT FLY may be prevented from laying its eggs on the Carrots by the means above mentioned. As a protection against the Carrot fly the earth round the roots should be kept as firm as possible, and when thinning them the first time it should be done so thoroughly, that the operation need not be repeated, keeping the crop in vigorous growth by suitable manures and waterings.

EARWIGS late in the season often prove annoying; hanging pieces of Reed or any hollow stem (those of the Sunflower being rather sweet are particularly useful) on plants and in places where they abound is as good a means as any of catching them; they are sure to creep into them, and may easily be shaken out and killed.

THE BLACK VINE BEETLE is often a great pest not only in vineries, but in conservatories, by destroying the leaves of various plants grown for their foliage. They feed at night and may be caught on the plants or by spreading a sheet under them and entering the house after dark quickly with a bright light, when they will fall, feigning death. If they do not fall a sharp tap or shake will bring them down. Their grubs are very destructive, and may be found feeding on the roots of Cyclamens, Primulas, Sedums, Strawberries, and various other plants.

RED SPIDER may generally be kept in check by affording a proper amount of moisture to the plants likely to be attacked. Sulphur is particularly obnoxious to it; any insecticide containing it is useful. The following mixture will be found very efficacious in destroying it: boil in 2 gallons of water half a pound of flowers of sulphur and 1 pound of fresh lime, add three-quarters of a pound of soft soap, and, before using, $1\frac{1}{2}$ gallons more water. G. S. S.

Turnip fly.—On warm, dry soil there will be some difficulty in keeping young Turnip plants free from fly this year, as the weather through May and the first half of June has been brighter than usual. The best plan is to pulverise the land well, that is, get it into a fine tilth. I am assuming that it is in good heart as regards manure. Sow in drills, having first soaked them with liquid manure. After the seeds are sown scatter a little superphosphate in the drills before covering in the seeds. Amies' manure is also useful, and a good substitute for the phosphate. I have also had great success with guano and salt mixed together. A comparatively small quantity will be of great value in hastening the crop when sown in the drills. Three pounds of guano and two pounds of salt thoroughly mixed and blended together will be enough for a rod of land. After the plants are up, lime is said to be a good dressing dusted along the rows, and frequently stirring the surface tends to disturb and keep off the fly. —E. H.

Pear tree borers.—I send a small piece of branch of a Beurré Bachelier Pear which was growing in a procumbent position and which I cut off close to the union with the stock. On cutting it through a yellowish green fluid covered the knife, and on examining the part severed I found it was produced by a large grub or caterpillar of a yellow-buff colour which quite filled the hole bored up the centre of the branch. The Pear tree is a young one purchased last year from a nursery in Naples, and the hole extends at least 6 inches in depth down the stock, which, I may say, is only 12 inches out of the soil, and is eaten quite smooth. Have any of the readers of THE GARDEN ever noticed a similar thing? Is it usual for grubs to be in Pear and Apple trees; and in this case is the grub indigenous to Italy or some others of the southern states? May it not be possible for us to import some new form of caterpillar in purchasing trees from that country? I filled the hole in the stock with petroleum to kill any larvæ that might be left in it. —C. BRAY, Whitbourne Hall.

Gooseberry caterpillar.—Now that the season has come when the Gooseberry caterpillar makes its presence known by divesting the trees of their foliage, I think it should be generally known that this unwelcome visitor may be quickly dispatched by syringing the trees with a solution of Gishurst Compound; about from 2 ounces to 3 ounces to the gallon of water will do, taking care to thoroughly wet the foliage and wood. I have also tried this season a decoction of the common Foxglove (*Digitalis purpurea*), with the same results, viz., dead caterpillars, but I prefer the first remedy, as the foliage and fruit look much cleaner after it, and do not require so much syringing with clean water afterwards, i.e., if rain does not come to wash them instead. On looking over the trees affected, I find here and there a handsome spotted caterpillar. Does it belong to the same family as the ordinary one? —C. BRAY, Whitbourne Hall. [See page 513.]

FLOWER GARDEN.

CULTURE OF THE SUNFLOWER.

Of late years Sunflowers have become favourites for decorative purposes in many places, and if not yet to be found in every garden it is not because there is no desire to possess them. They are easy to cultivate and sure flowerers, the only secret as regards perfect success lying in sowing the seed. Last year we sowed some seed in a hothouse early in March, and from the plants thus raised we had blooms in July 15 inches in diameter. More seed was sown in the open ground in April, but the plants produced in this case did not bloom until far on in the autumn, and were never so satisfactory as those raised and brought forward under glass. I would, therefore, advise all who have the means to raise their Sunflowers under glass, and treat them like half-hardy bedding plants. We do not bestow on them much labour or attention. Two or three dozen seeds are sown in an 8-inch pot in any light soil, and this is placed in a house or hotbed until the plants are pushing through the soil, when they are brought close up to the glass, and there they remain until they are about 3 inches high, when they are turned out of their pots and planted in our cutting boxes, which are 2 feet 6 inches long, 18 inches wide, and 4 inches deep. A few rough leaves are placed at the bottom of each box, which is then filled up with a mixture of loam and leaf-soil or old Mushroom bed manure, and into this the Sunflower plants are dibbled from 2 inches to 3 inches apart. In this way half-a-dozen boxes hold a great many, and they do not take up much space. As the boxes are filled they are placed in a temperature of 60°, and here the young plants soon begin to grow away rapidly, reaching a height of from 18 inches to 2 feet in a month's time. By the beginning of May they are hardened off and are ready for planting out anywhere according to fancy. Some plant them in a group by themselves, others place them in herbaceous borders, and not a few plant them about shrubberies. A deep rich soil is most suitable for them, as the blooms never gain any great size in poor ground. As soon as they are planted a stake should be put to each, and as the leading stem produces the first bloom, this may be cut off as soon as it is past its best, in order to induce the side shoots to push up and also bloom. All strong growing plants will do this, and they will continue to produce a succession of flowers until well into the autumn. J. MUIR.

Margam, South Wales.

HARDY AROIDS.

AMONGST hardy Aroids, *Arisæma triphyllum*, the American Jack in the Pulpit, is decidedly worth growing, owing to its quaintness. When it first appears above ground it is like a brown mottled horn. The flower is placed between two trifoliate leaves, and is really not unlike a little figure in a pulpit, with a sounding board overhead. The plant is about $1\frac{1}{2}$ feet high, and grows well in a bog bed or in ordinary damp soil.

ARUM ITALICUM is also flowering well this year, and although it is very like the wild *A. maculatum*, it is sufficiently distinct to be worth growing were it only for the leaves, which are usually veined with white in spring. This plant and *Arum Draunculius*, with its dark brown flowers, do not require a choice spot in which to grow; the latter does not blossom freely here. The scent is sometimes (happily, very seldom) extremely strong and disagreeable.

CALLA PALUSTRIS is small enough to grow even in a tub, and would probably grow equally well as a bog plant. The well-known Lily of the Nile, *Calla æthiopica*, is hardy in this neighbourhood (when grown as a water plant) except in very severe winters. In a bog bed during the summer it is very effective. A collection of all the good hardy Aroids in cultivation would be both curious and interesting. The description of the common wild *Arum maculatum* in chap. 2 of Sir John Lubbock's "British Wild Flowers in Relation to

Insects" is one of the most interesting parts of the book; and probably many other points of equal interest are to be found in other Aroids.

Knockmullen, Gorey, Ireland.

DWARF ANTIRRHINUMS.

THAT remarkably dwarf strain of the Snapdragon originated on the Continent, and for which we are specially indebted to Messrs. Vilmorin, of Paris, has by no means become so well known or widely grown as it should be. The dwarf forms belonging to this strain are exceedingly beautiful, not only because they are dwarf, but because they all possess such charming variety in the way of colours and markings. The Continental growers have by dint of patient selection succeeded in getting distinct colours, so that of the mauve type and of the Tom Thumb type, which is even dwarfer, there are

Dwarf Snapdragon (*Antirrhinum majus* var. *pumilum*).

some twenty or more distinct forms. Some are sold under name, some according to colour, but the most striking are those in which some two or three colours are found in combination, either in the form of stripes, blotches, or clearly defined margins. It is a curious fact that the tall forms, though rich in variety of colours, yet lack many of the curious hues found in the dwarf section; hence if a bed be planted with the tall kinds, and margined with dwarf ones, a very charming effect is the result. It is to be regretted that in all gardens of any great size there is not set apart a few beds in some appropriate place, in which such good biennials as Snapdragons, Pentstemons, Sweet Williams, &c. can be grown, as whilst in bloom, and the season is a long one, they make beautiful masses of flower. They also furnish an ample supply of cut bloom, and, not least, they present variety in form and colour in garden plants that is singularly acceptable. When, further, it is known that all these biennials can be raised from seed, which may be purchased cheaply, we can but marvel that they are so little grown. Of this dwarf strain of Snapdragons the annexed illustration is a good example of the way in which they grow and flower. Exhibitors of Antirrhinums in spikes may not care for these dwarf forms, as their spikes of bloom are not sufficiently large for their purpose. But for pot culture, and it is as pot plants that for exhibition purposes Snapdragons should be encouraged, these dwarf kinds are admirably suited. From 8 inches to 12 inches in height, carrying when at their best a dense head of bloom in such admirable variety, they would, shown in dozens or less, make a capital class, and several collections would form a charming feature in any show. Seed may be sown at almost any time of the year, but much must depend upon the particular time at which the plants are desired to be at their best. A little seed sown

early in March in a pan and placed in warmth will give an ample supply of plants to flower at mid-summer, and a couple of later sowings will keep the supply up to the winter, so that the time of holding any show might easily be arranged for, and the surplus plants put out into beds or borders will prove serviceable for garden decoration. It is better to sow seed each year, as it is found that in the second year the plants yet taller if they stand the winter. As they come so true from seed, several beds may be filled with masses in colours, and thus produce a cheap and an effective display.

A. D.

NOTES ON IVIES.

WITH so many naked and unsightly walls to cover and beautify, a good deal more should be done with the better kinds of Ivies. I am not finding fault with our old friend, the rapid growing Hibernian Ivy. I admit its value everywhere, but variety is charming, and those who can afford to wait should plant the choicer slower growing kinds. They are easier to keep in order, and they impart a character of refinement to a wall or building that scarcely anything else in the same way can do. I have the following kinds growing on the north side of my house, viz., *Hedera aurea maculata*, leaves three-lobed, small, but of the brightest gold. *H. marmorata elegans*.—This also is a small variety, but very close and neat, foliage not much divided, marbled with creamy white. *H. palmata*.—Leaves small, five-lobed, deeply serrated, bright golden, but not so bright as the first named. This is a free grower. *H. elegantissima*, a very neat variety, with leaves heavily variegated with white, the new foliage having a faint, but distinct margin of pink; a slow grower, but does its work as it proceeds, and costs nothing to keep in order. *H. Emerald Gem*, a beautiful dark green variety, very close in habit. These are young as yet, but large enough to show what they will be by-and-by when they cover the wall. I intend to keep them distinct, permitting each to fill its allotted space, and no more. *H. latifolia maculata* is a variegated form of the Irish Ivy, and partakes of its robust character, but it is planted in a spot where it can get on to the chimneys, and will have more work assigned to it. All these Ivies are very easily propagated by means of cuttings. If the soil is bad and ungenial it is better to replace the worst of it with something better, in order to give the plants a fair start.

E. HOBDAV.

DRESSING FLOWERS FOR EXHIBITION.

I HAVE read the different remarks which have appeared in THE GARDEN recently on this subject, especially those relating to the dressing of Carnations and Picotees for exhibition, with a peculiar kind of interest, because they raised in my mind another question intimately connected with the progress of horticulture. It is this: Is this artificial system of presenting flowers to public view necessary? In my opinion it is not, and what is more I maintain it is misleading, because on the strength of what people see at exhibitions many are induced to attempt the growth of florists' flowers without having any idea that the productions which they have been admiring are to a great extent artificial; they are not as Nature formed them, and, therefore, without having acquired a knowledge of the art of dressing, they find in time that they cannot reach the standard at which they aimed, and which they were led to expect they would do. They, therefore, become disheartened, saying, "I cannot think how it is that I cannot grow my Dahlias, or Chrysanthemums, or Carnations in such perfect form as those which I saw," naming the exhibition at which they were first induced to begin florist flower growing.

In justice to all whom it may concern I think this state of things should be altered. I have no wish to interfere with the functions of florists, but if I was a manager of a flower show I would insist on their presenting their productions at an exhibition to which the public was invited in a legitimate manner. Upon every stand of flowers, be they

what they might, upon which any dressing had been performed a card should be placed, stating that the flowers had been dressed. The inexperienced could then understand whether they possessed sufficient of the florist's knowledge to undertake the cultivation of such plants with any prospect of success or not, and they would act accordingly. It is not the professional gardener who needs teaching the mystic art of the florist, for, as a rule, he is familiar with the share that the tweezers, the gum-bottle, and the invisible pins take in the work, but I write in the interest of the garden-loving public who have not had the opportunities of learning all the details of the profession. These are sure to meet with sufficient failures in conducting their gardens from unavoidable circumstances, and when florists place before them their skilfully manipulated flowers, I contend that they place themselves in a false position unless some means are adopted of informing them that skilful manipulation has been resorted to in order to bring before the public flowers with perfect forms and outlines.

J. C. C.

Linaria pallida.—I planted a little bit of this in the front of a border three years ago; it is now a yard in diameter and literally covered with little violet-coloured flowers. Unlike most of the Toadflaxes, it creeps under ground instead of above it. Many, indeed most, low growing plants should be encouraged to develop into patches large enough to be effective. To do this in some instances it would of course be necessary to plant five or six plants in a group.—E. H.

Lathyrus Sibthorpei.—Among border flowers at this season, this hardy perennial Pea is one of the most showy. So far as I know, this is the earliest of the tribe, but will be glad to learn from any of your correspondents if I am correct in this. With me it has been flowering freely for a month past, and promises to continue so for at least another. It grows about 3 ft. high, and where spring bedding is carried out nothing could be more effective for a background. It appears to be almost unknown in private gardens, and, except in Parker's, of Tooting, no nurseryman's list that I have seen contains it. It is cultivated in Glasnevin Botanic Garden and doubtless in other similar establishments, though I do not happen to have observed it anywhere else.—P. NEILL FRASER, *Murrayfield, Edinburgh*.

Limnanthes Douglasi.—This beautiful annual has lately been covered with showy flowers, but it does not bloom quite early enough for what is usually termed spring bedding, being just at its best at the end of May, when the beds have to be cleared for their summer occupants. It, however, well deserves a place where it can finish its flowering. If sown in September either where it is to flower or in a seed bed and transplanted as soon as large enough to handle, it will be found to be most effective in May and June.—J. G., *Hants*.

Polyanthus Primroses.—These should quickly take rank amongst the best spring flowers for garden decoration. Everyone who sees them likes them, and they not only make a great show in the border, but are very useful for cutting. My two-year-old plants have been more or less in bloom since February, and have just finished up with a burst of from fifteen to thirty trusses to each plant, each truss consisting of from six to twelve flowers. Both with these and with seedling hybrid Primroses I find the culture usually advised to be erroneous. Primroses are usually recommended to be watered and kept growing during summer. I find these kinds much better for a good roasting in hot weather, so long as they are not allowed to die. With this treatment the whole summer growth seems to go to the production of flower-buds, and when the autumn rains come only a few leaves are produced, and then they start flowering. This is a great advantage, for the first flowers, having long individual stems, are not hidden by leaves, but appear like a market bunch of Violets—a solid mass of flowers with a circle of leaves round it. When the leaves begin to grow

the truss flowers rise, and after the bloom is over the principal production of leaves takes place; then the plants go to rest for the summer. Everyone having a garden should buy a few plants of these Primroses, and sow seed direct from the seed pods as soon as it is ripe. A plant that can be trusted for two months' continuous bloom is certainly an acquisition for the spring garden.—J. D., *Barnet*.

Hardy Geraniums.—The following are half-a-dozen good kinds which everybody should grow, being superior to many of the things cultivated in borders: *G. ibericum*, a kind having very large purple flowers, tinted with violet, is one of the best, especially for early flowering; with us the blossoms are now fast opening. *G. armenum*, purplish crimson, and *G. sanguineum*, crimson, are both showy and useful sorts; the latter is hardly ever out of flower in summer. *G. cinereum* has white flowers, finely striped and pencilled; it is dwarf in habit, and looks best on rockwork or on some elevated site. *G. pratense album*, also white, and *G. p. plenum*, purple, are striking, robust-growing varieties. Both have bold, deeply serrated leaves, mounted on the ends of long stalks, and their flowers open in succession for a long time. Strong plants of these look well isolated on Grass. They only require good cultivation, such as should be given to all plants expected to give satisfaction, and all of them are easily propagated by division in spring.—E. H.

Ranunculus repens fl.-pl.—You remark (p. 509) that Mr. Ware's *R. speciosus* is the same plant as this, but I have the two growing side by side and they are quite dissimilar. *R. speciosus* has by far the larger flowers, and it does not creep along the ground as the other does, but forms a solid clump and has an erect habit. It sends out runners, of course, as all the class do. *R. acris fl.-pl.* is another common garden variety very similar, but with smaller flowers. There is still another, more floriferous, taller, and every way a better garden plant, viz., *R. lanuginosus*, which I see was introduced from South Europe in 1683. It is by no means common, but it abounds with us; I had it from Tooting about six years ago. Although our variety of *R. repens fl.-pl.* was found wild as stated in your last, I see it was in the Cambridge Botanic Garden list of 1845, so it is not a new plant. Our common meadow Buttercup is *R. repens*, and as this is merely a double form of it, there will probably be many such found if search be made for them. *R. Ficaria*, the Lesser Celandine, has also been found both in its double yellow and its single white form in the meadows hereabouts, and they are growing here. These are two very pretty varieties.—WM. BROCKBANK, *Brockhurst, Didsbury*.

Self-coloured Daffodils.—Against "F. W. B.'s" opinion that there is no such thing as a real self yellow Daffodil (p. 522), you must set the published opinions of the following, who are all well known and thoroughly competent judges, and then decide which carries most weight, viz., Rev. H. Ewbank, Rev. C. Wolley Dod, Mr. Archer-Hind, "Rho," Mr. Douglas, Mr. Leo H. Grindon, Mr. Henry Brownhill, of Sale, Mr. Wm. Yates, and myself. All these names have been published during this discussion, in THE GARDEN, as witnesses, having seen truly self-yellow Daffodils, and with especial reference to this discussion. Mr. Barr said he had a yellow one. I, therefore, hold that the existence of self-yellow Daffodils has been established, and I can reasonably say, without any shadow of injustice to Mr. Burbidge or any lack of generosity, that if a stakeholder had held Mr. Burbidge's kettle it would probably have found a place in my museum.—WM. BROCKBANK, *Brockhurst, Didsbury*. [Here we think this discussion should stop—at least for the present.]

5001.—**Heuchera Richardsoni**.—This may certainly be procured from Barr & Son, and possibly from Messrs. Ware and Backhouse as well. It has rich brown tinted leaves of satin-like lustre, hence the popular name of Satin Leaf, and its foliage, which is freely produced, is well adapted for cutting, being both beautiful and enduring in water indoors.—B. W.

LARGE-FLOWERED PLANTAIN LILY.

ONE of the noblest of hardy plants and of the highest utility in beautiful gardening, whether grouped among summer and autumn flowers or used separately in masses, is *Funkia grandiflora*. It is one of the plants, of which there are many, that are brighter in shade than in sunlight, hence perhaps its best place is in woods and the shadier parts of gardens, where its vivid light green leaf-colouring and pure white flowers may have their full value seen against darker masses of leafage

ORCHIDS.

PEAT FOR ORCHIDS.

"J. S. W." may rest assured that the peat which he describes as being composed of Fern roots mainly is well suited for Orchids, and I doubt if any material can surpass it, as being so tough it is a long time in rotting, a most important point in Orchid culture. Many Orchid growers will, I am sure, be wishing that they were so favourably circumstanced as your correspondent, but as a fact

many other peat-loving plants will not; at any rate they do not last out when grown in it without the admixture of some other kind of soil. This is especially the case with Ericaceous plants, notably the hard-wooded kinds. For tender-rooted Ferns it is well suited, but strong-growing kinds demand more nutriment than it affords. I do not know of any better material than it is for drainage; one good sized crock and a few pieces of this peat are quite as good and even better than half-an-inch of crocks, and that the roots love it is evidenced

Large-flowered Plantain Lily (Funkia grandiflora)

or shadowy places. The Lily-like flowers are strongly scented like the white Lily, too strongly to be available for use indoors, but the leaves are always beautiful in important decorations of cut flowers and last long in water. As to flowering, this fine plant appears to be somewhat capricious, flowers appearing abundantly some years and not at all in others. It flowers best in a warm sandy soil, though the plant has a rather larger development in a stiffer one. Exposure to very hot sunshine is apt to turn the leaves yellow and wither them at the edges; this also points to the desirability of placing them in shade rather than in bright light.

G. J.

this kind of peat is not to be found everywhere, and is as difficult to procure in a general way as the Kentish peat. A few years ago this description of peat was obtained on an estate here, but as soon as growers in the neighbourhood and the London soil merchants became aware of the fact, they drew upon it to such an extent, as to quickly exhaust the supply. I agree with "J. S. W." that the mechanical rather than the chemical composition of the compost has to be considered in Orchid growing, else why do we often see such fine specimens in Sphagnum and charcoal alone? A proof of this lies in the fact that whilst Orchids thrive admirably in the peat above alluded to

by the fact that they always fill it with healthy fibres. For one thing especially I recommend this light peat, and that is for Lilies, especially *auratum*; they thrive admirably in it. I have had *L. lancifolium* growing in it, large specimens bearing hundreds of flowers, and perfect as regards health and size of foliage.

J. C.

Byfleet.

Cattleya nobilior.—This beautiful new *Cattleya*, certificated lately from M. Linden's nursery at Ghent, may now be seen in flower in Mr. Peacock's collection at Sudbury House, Hamersmith. It is a splendid variety; bearing two

fully developed flowers, and will, doubtless, prove a valuable addition to the genus, being distinct from all others and very dwarf. In Mr. Peacock's garden there is also the finest variety of *Cattleya Warneri* we have ever seen, both as regards the size of its flowers and their colour.

Three-leaved Twayblade.—I have frequently come across the Twayblade (*Listera ovata*) with three, and in one or two cases with five, perfectly formed leaves. All the plants of this kind I can remember were found growing in a wood, and where the soil was unusually rich, and the specimens consequently large and vigorous. As in many other cases of abnormal plant growth, this freak of Nature, or whatever else it may be called, is not constant under cultivation; at least it has not been so in my case. Have any of your readers found the cordate-leaved Twayblade (*Listera cordata*) plentiful? If so, I should like to know.—A. D. WEBSTER, *Llandegai, Bangor, N. Wales.*

Cattleya Mossiæ.—I send you a spike of this *Cattleya*; it is from a plant in a 6-inch pot. It bore four spikes, two of which had two blooms on each; one had three, and the one sent had four, in all eleven blooms, and this an average bloomed plant. When the plant came into my possession, two years ago, it had only one leaf on it. The plant from which the spike in question was cut has been in bloom three weeks, and most of the time on a table in a drawing-room.—JOHN CROOK, *Farnborough Grange, Farnborough.* [A beautiful variety, remarkable for the large size of its blooms, which are delicate in colour as regards the sepals and petals, and rich in the colour of the lip.]

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 12.

THIS meeting was a small one as regards the number of plants exhibited, though the few produced were highly interesting. The following were awarded first-class certificates:—

LILIUM LONGIFOLIUM VAR.—This was shown by Mr. G. F. Wilson, Heatherbank, Weybridge, as the Easter Lily of Bermuda. It was some 5 feet high, and bore five large pure white waxy blossoms with tubes 8 inches or 9 inches long.

CYCAS ELEGANTISSIMA.—An elegant plant with long, gracefully recurved, pinnate leaves of leathery texture and of a deep shining green colour. It forms a valuable decorative plant, being well furnished with foliage even in a small state. Exhibited by Mr. B. S. Williams.

MIMULUS RADICANS.—A charming little species, presumably hardy. The whole plant, including the flowers, is not more than an inch high, and the small oblong bronzy foliage forms a dense turf, on which are studded the showy blossoms, each nearly an inch across. The three lower lobes are pure white and the two upper ones bright purple—a combination which, with a dash of yellow on the crest, makes a sweetly pretty flower. Exhibited by Messrs. Veitch, Chelsea.

TROPEOLUM LUSTROUS.—A dwarf variety, not more than 9 inches or 12 inches high, compact and robust in growth, and so free as regards flowers as to be a mass of brilliant fiery scarlet. It, therefore, cannot fail to be a valuable bedding variety. Exhibited by Mr. R. Dean, Ranelagh Road, Ealing.

PELARGONIUM DR. MASTERS.—A seedling hybrid Ivy-leaved variety, raised and exhibited by Mr. George, Putney Heath. It is similar to that shown on the last occasion under the name of Masterpiece. The flowers and truss are large, and the colour, a carmine-crimson, is very brilliant. It appears to be robust in growth, and is as free a flowerer as the other hybrid Ivy-leaved sorts.

ROSE PRINCESS OF WALES.—This is one of the new seedling pedigree Roses raised by Mr. H. Bennett, Shepperton, who exhibited it. It is a Tea variety, with large, beautifully shaped, sweet-

scented flowers, the petals of which are of thick texture, and recurve at the edges like those of *La France*. The colour seems to vary from a delicate blush-white to a pleasing soft rose-pink, beautiful in all its phases. Some two dozen trusses were shown, cut from open-air plants.

PELARGONIUM FORMOSA.—One of the decorative class, vigorous in growth and an abundant flowerer. The trusses are large, the flowers of good shape, and brilliant scarlet, blotched with black and edged with white. *P. FANNY*, also a decorative variety, furnished with large trusses of light rose-pink blossoms with wavy-edged petals. The plants measured some 2 feet through. Both exhibited by Messrs. Hayes, Edmonton.

POLYSTICHUM ACROSTICHOIDES GRANDICEPS.—A hardy exotic Fern, having the pinnae of the fronds terminating in a crest, which makes the plant very handsome. Shown by Messrs. Birkenhead, Sale, Manchester.

ADIANTUM NOVÆ-CÆLEDONIÆ.—An elegant new Maiden-hair Fern of dwarf growth, having finely cut pedate fronds. Messrs. Birkenhead.

A group of choice plants was exhibited by Mr. B. S. Williams, Victoria Nursery, Upper Holloway. The most remarkable plant in it was a fine specimen of *Nepenthes excelsior*, a new variety in the way of *Rafflesiana*. It bore enormous pitchers, the finest we have seen. One measured fully 9 inches in length, and all were richly coloured. There were seven such large pitchers on the plant, for which a cultural commendation was awarded. The other plants in the group comprised a fine basketful of *Carnation Souvenir de la Malmaison*, with huge flowers; a fine potful of *Orchis foliosa*; two fine varieties of *Cattleya Mossiæ*; *Anguloa Ruckeri sanguinea*, a richly coloured and distinct variety; *A. Clowesi*; *Cypripedium superbiens*, a fine plant with seven flowers; *Crassula jasminiflora*, and a hybrid *Amaryllis* crossed with *Sprekelia formosissima*, which is, however, no great beauty. These bright flowering plants were intermixed with such beautiful fine foliaged plants as the *Adiantum bipinnatum*, *Pteris ascensionis*, a new species in the way of *P. straminea*, *Dracæna Lindenii*, and a collection of *Anacochili*, *Goodyera*, and *Microstylis*. A group of hardy shrubs was shown by Messrs. Veitch, from their Coombe Wood Nursery. It included some fine branches quite wreathed with clusters and white blossoms of *Viburnum plicatum*. Among new Japanese Acers were *cratægifolium*, *linearilobum*, and *decompositum*, and *ribesifolium*, the last three varieties of *A. polymorphum*. The new white *Populus Bolleana* was also shown in this interesting group.

CATTELEYA GIGAS SANDERIANA was shown as a very fine specimen by Mr. Brymer's gardener (Mr. Powell), Puddleton, Dorchester. The plant, in a 12-inch pot, bore five spikes, eleven flowers in all. The flowers were large, but with rather narrow sepals and petals; the labellum, however, was very broad and open, of a rich amethyst tint, exquisitely grained with white. A large white and yellow blotch in the throat was a beautiful contrast to the colour of the labellum. For this fine specimen the exhibitor was awarded a cultural commendation. *Lælia majalis* was shown very fine by Sir Charles Strickland, Hildenley, Malton. A large mass growing in a cork basket bore three large flowers of a deeper rose-pink than usual. A cultural commendation was awarded. A marvellously fine variety of *Odontoglossum crispum*, named *Thompsoni*, was exhibited by Mr. Stevens, gardener to Mr. Thompson, The Mount, Walton Stone. The flowers were 3½ inches across, with a white ground heavily blotched with chestnut-brown. It is in the way of *Chesteroni*, but the finest form we have seen. Double *Begonias* from Messrs. Laing included the two fine varieties shown at the last meeting, named *Dr. Duke* and *Prince of Wales*. Both have very large rosette-like blossoms, the first of a bright scarlet, the other a deep crimson. A new seedling Maiden-hair Fern was shown by the General Horticultural Company. It was a beautiful variety in the way of *A. tenerum*, and was a fine specimen. A new *Caladium*, named *C. F. Bause*, also came

from the same exhibitors. It is a small, dwarf-growing variety, with heart-shaped leaves of a deep red bordered with green.

TROPEOLUMS in variety were shown by Messrs. Carter & Co., High Holborn. About a dozen sorts were included in the collection, all being of the dwarf Tom Thumb race. The following were particularly noteworthy: *Tom Thumb* (yellow), *Golden King of Tom Thumbs*, *Tom Thumb Beauty*, *Ruby King of Tom Thumbs*, and *Spotted King of Tom Thumbs*, all of which were distinct and beautiful, and appropriately named. Other fine sorts were *Empress of India*, *Géart des Batilles*, and *Zanderi nigrum*, a very dark variety of the climbing Lobbianum type.

A most extensive group of cut hardy flowers was exhibited by Messrs. Barr & Son, King Street, Covent Garden. It consisted of Oriental Poppies in variety, including *P. bracteatum*, double and single *Pyrethrums* in great variety, *Pæonies* of all shades, from crimson to white, *Lupines*, *Camassias*, *Lillies*, *Iceland Poppies* (*P. nudicaule*), and *Irises*, of which there was a marvellous array, comprising, we should imagine, every known variety of the Bearded Iris. The arrangement, too, was admirable, as each class or variety was represented by a distinct bold mass, which is a much better way of arranging, we think, than intermixing the whole of the varieties. A gold medal has been deservedly awarded to Messrs. Barr for this fine group. An extremely fine collection of choice hardy flowers was also exhibited by Mr. T. Ware, Hale Farm Nursery, Tottenham, which afforded a rare treat to the visitors, as so seldom can such a choice group be seen at a show. There was a large number of the finest hardy plants represented, the cream of them being *Cypripedium spectabile*, very fine; *Campanula dahurica*, *Brodiaea coccinea*, *Dodecatheon splendendum* and *Jeffreyanum*, Spanish *Irises*, Bearded *Irises* in great variety, Oriental and Iceland Poppies, double and single *Pyrethrums*, *Orchis foliosa*, *Lychnis Viscaria fl.-pl.*, splendens, a very fine plant, *Tropæolum polyphyllum*, and *Mertensia sibirica*. The above are but a few of the host of plants sent by Mr. Ware, for which he was awarded a silver medal.

FRUIT AND VEGETABLES were not numerous. Some excellent samples of Lord Napier Nectarines were sent by Mr. Stevens, Trentham, and two fine dishes of James Veitch and Sir Joseph Paxton Strawberries were shown by Mr. Goldsmith, Hollenden, who was awarded a cultural commendation. Mr. Laxton sent a new Strawberry called *King of the Earlies*, said to be earlier even than *May Queen*. It was recommended to be tried at Chiswick. Messrs. Paul, Cheshunt, also exhibited a new Strawberry named *Pauline*. A seedling Melon was sent by Mr. Herrin, Chalfont Park, named *Chalfont Hybrid*. Mr. Henderson, Thoresby, also sent a seedling Melon, but neither were commented upon by the committee. Messrs. Veitch exhibited a new Turnip named *Extra Early Milan*, apparently an excellent sort. It was awarded a first-class certificate.

ASPARAGUS PRIZES.—On this occasion the prizes offered by Mr. Robinson for *Asparagus* were competed for. There were more competitors this year than hitherto, and there was a marked improvement in the quality of the *Asparagus* throughout the whole of the sixteen bundles shown. The chief prizes were offered for 300 heads, to be competed for by market growers. The best bundle was exhibited by Mr. Harwood, Colchester, whose heads were uniformly large and in just the right condition for eating. The second bundle, from Messrs. Poupart, Kew, was also good, but the heads were rather too much open. There were six competitors in gardeners' and amateurs' classes. Mr. Cole, Colchester, showed the finest bunch of 80 heads, all of which were large and good, and indicated good cultivation and selection. The next best 80 heads were from Lord Suffield's gardener (Mr. Allan), Gunton Park, Norwich. This was also a fine bunch, but the heads were not so large as those from Mr. Cole, nor so uniform in size. The third bundle came from Mr. Speed, Penrhyn Castle. It represented excellent growth, but had selection,

that is, the heads were not of uniform size. The fourth bunch, from Mr. Pitt, Bury Hill, Dorking, consisted of small heads, but were uniform and succulent. Mr. Ward, Longford Castle, and Mr. Stewart, Maldon, also competed in the class for eighty heads. There were four bundles of fifty heads. The best were from Mr. Allan and Mr. Herrin, Chalfont Park, and Mr. Stewart took the other two prizes in the order named.

Pelargonium Society.—At this meeting the Pelargonium Society awarded first-class certificates to the two following Pelargoniums, both shown by Messrs. Hayes, Edmonton. They were, Fanny, a decorative variety of vigorous and compact growth, and producing large trusses of large rosy pink flowers, with prettily wavy-edged petals, and Garibaldi, also a decorative variety, possessing all the qualities desired in this class, and remarkable for its brilliant colour.

SCIENTIFIC COMMITTEE (Sir J. D. Hooker in the chair).—*Carnivorous habits of Cyclobothra pulchella.*—Mr. W. G. Smith exhibited drawings to show how this flower catches minute insects by means of long hairs on the perianth. The inner leaves of the perianth close over the flower and are provided with honey glands, and these are protected by long hairs which detain the insects and appear to consume them somewhat after the manner of the Sundew.

Æcidium sp.—He also brought several instances of plants attacked by this fungus, which appears to be extremely common this year. They were sent by Mr. Plowright, including *Æ. Thesi* on *Thesium linifolium*, from Mr. Straker, which was quite red with it. From Mr. Plowright came *Æ. rubellum*, forming large circular spots on Rhubarb leaves. *Æ. berberidis* on wild and cultivated Barbery as well as on *Berberis Aquifolium*. The last species he had proved, thereby corroborating former investigations by other experiments that it gave rise to wheat rust, but he also asserted that *Æ. rubellum* on the Dock and Rhubarb was identified with *Puccinia phragmitis* (*P. magnusiana*). Mr. G. Murray observed that he had found *Æ. berberidis* on *B. Darwini*.

Euplexia lueifera.—Mr. Pascoe showed this day-flying moth, the caterpillar of which attacks the roots of Ferns, both wild and cultivated in ferneries.

Seeds of Niphion (?) or Colchicum (?)—Dr. Lowe showed pink and white oval seeds which were found on the Grass. They were thought to be seeds of some Iridaceæ. They were referred to Kew.

Disease on Melons.—The Hon. and Rev. Mr. Boscawen showed Melon leaves diseased, apparently by some fungus. Mr. Murray suggested it might be *Peronospora parasitica*, but it was too immature to say. He retained the specimens for report.

Ampelopsis Veitchi with gummy exudations.—Mr. Moore exhibited specimens of dead branches with curious red filamentous processes, soluble in water, and appeared to be gum.

Apples attacked by caterpillars.—From Rev. C. N. Sowell, of St. Austell, came shoots of Apple trees, which Mr. Boscawen said he was familiar with as attacked by small caterpillars. Mr. Smith remarked that similar appearances are produced by *Helminthosporium pyrorum*, but this fungus was not apparent on the specimens.

Japanese Varnish Plant (*Rhus vernicifera*?).—A plant was exhibited by Sir C. Strickland.

Cabbages with maggots.—Dr. Masters exhibited plants attacked by what appeared to be some species of *Lixus*.

Plants exhibited.—*Sarcopodium Dearei*, probably new, from Lieut.-Col. Deare; it had a fine orange-coloured blossom with the peculiar oscillating lip of the genus. *Mimulus radicans*, a very pretty species with white flowers and one purple petal, and with the leaves closely adpressed to the soil.

Evening meeting.—The second evening meeting of the Society at Burlington House took place last Tuesday.—Lord Aberdare in the chair.

As on the last occasion, the library was filled with a variety of interesting plants and cut flowers. Glorious gatherings of Orchid flowers were contributed by Mr. Lee, of Downside, Leatherhead, and Sir Trevor Lawrence. Among these were splendid *Cattleyas*, *Lælias*, *Odontoglossums*, and *Epidendrums* arranged in one effective group. A collection of *Rhododendrons* and *Azaleas* from Mr. Mangles, Valewood, Haslemere, was much admired, especially the larger species, such as *R. calophyllum*, of which there were some fine trusses. *R. cinnabarinum*, *R. triflorum*, and *R. javanicum* were also shown by Mr. Mangles, besides a whole series of varieties of *Azalea indica* cut from the open air.

A large collection of interesting plants was sent from the Royal Gardens, Kew, among which were some gigantic spikes of *Agaves*, one 9 feet high, and the huge spathe of *Amorphophallus campanulatus*. Among other plants from Kew were *Crossandra undulatifolia*, *Nymphaea zanzibarensis*, and *Hoya campanulata*. A similarly interesting collection was shown by Mr. Lynch, from the Botanic Garden, Cambridge. It included among others specimens of the hardy *Asimina triloba*, *Peperomia resedæiflora*, and *Candollea tetrandra*. Mr. Loder also contributed an extensive collection of cut hardy flowers, and a similar collection came from Mr. Ewbank, Ryde; a group of rare plants from Mr. Maw, hybrid Irises from Dr. Foster, Pelargoniums from Messrs. Cannell, and hardy plants from Mr. Ware were also noteworthy. In the lecture room was an extensive collection of plants and flowers of *Cypripediums* contributed by Sir Trevor Lawrence, Mr. Lee, Messrs. Thompson, of Clovenfords, Messrs. Veitch, Williams, Ware, and others, for illustrating the paper on *Cypripediums*.

A pleasant feature was an arrangement of hardy flowers by Miss Jekyll. The object was to prove how they lend themselves to the highest class of indoor decoration. Miss Jekyll had no difficulty in showing this by several graceful groups, though the limited space in which they were placed restricted her from making as good combinations as she might otherwise have done. In her groups the Day Lilies were remarkable for their fine form and graceful habit. A large simple vase of great Poppies was very effective and well composed. Well-grown plants of the white Plantain Lily (*Funkia grandiflora*) were excellent in low, wide metal vases. They were not in flower, but their cool nests of fresh green leaves were excellent, and would be useful in the same way in halls or rooms. To place a number of vases of flowers rather closely associated together in this way is difficult. If fine, bold, and free forms are used, a large space round each is essential to the enjoyment of the picture. That is, why good vases seen separately in a house are enjoyed so much more. Perhaps the most delightful of Miss Jekyll's group was a huge dish of Scotch and Austrian Briers. It looked as free, and yet was as full of flower as the Brier bushes are. For fully eight months in the year fine and varied flowers and foliage may be gathered from any fairly stocked garden, and everything which promotes their good arrangement deserves our help and praise.

Dr. Masters commenced the proceedings by a few remarks upon peculiarities of growth in Conifers, particularly as regards the development of terminal buds. The peculiarity of the Silver Firs having a white appearance during the day and green towards evening was explained as due to the twisting of the leaves, the under side, upon which the majority of the stomata are found, being turned to the light in the day and reversed at night. Allusion was also made of the gyration of Pine branches, Dr. Masters stating that he had observed them make two revolutions in twenty-four hours, the apex being directed successively to all points of the compass. Specimens of the Californian *Pinus tuberculata* were also shown bearing numerous cones, which the lecturer stated never open unless the branch is killed or injured in some way by animals or forest fires. The seeds, which are winged like those of other

Conifers, are then wafted sometimes to a considerable distance, and there germinate and grow. Sir Charles Strickland stated that *Pinus pungens* has the same peculiarity of not opening its cones as *P. tuberculata*.

A paper on *Cypripediums* was next read by Mr. William Goldring, an account of which will be found at p. 531. It was illustrated by a numerous collection of flowers, representing all the sections of the genus. Sir Trevor Lawrence, in the discussion which followed, gave some interesting facts in connection with the cultivation of these Orchids and their commercial value. Mr. George Maw then read the following paper on the geographical distribution and culture of

Crocuses.

Out of a genus which is now known to number about seventy species, two only, *Crocus vernus* and *C. aureus* and their varieties, can be said to be thoroughly adopted as decorative plants. *Crocus vernus*, the parent of all the blue, violet, lilac, feathered, and white vernal Crocuses, ranges in a wild state through 23° of longitude, from the Pyrenees to the Carpathians, and through 12° of latitude, from Sicily to the Carpathians.

Crocus aureus, the parent of the Dutch yellow and its several varieties, is indigenous to Western Asia Minor, Turkey, and the Danubian Principalities, and extends as far north-west as Hungary. No records exist of the date of their introduction. It is clear from the Crocuses preserved in the various ancient herbaria consolidated in the "Herbarium Sloaneanum" at the British Museum, from the records in Gerard's "Flora" and in several other early English and Dutch works, that these two species at least were well known to cultivators at the end of the sixteenth century. The old herbaria contain, in addition to several wild species, complete series of all the varieties of *Crocus aureus* at present known, including *sulphureus*, *sulphureus pallidus*, *sulphureus striatus*, *lacteus*, &c. These were certainly not wild forms recently introduced, but degenerated horticultural forms of *C. aureus*, exactly identical with those we now cultivate, and imply a far-back cultivation of the wild *Crocus aureus*. In addition to *vernus* and *aureus*, eight or nine other species appear to have been sparingly in cultivation during the seventeenth and eighteenth centuries, viz., the Cloth of Gold, *Crocus susianus*, the Cloth of Silver or Scotch *Crocus*, *C. biflorus*, *C. versicolor*, *C. nudiflorus*, *C. sativus*, *C. speciosus*, *C. serotinus*, *C. byzantinus* or *iridiflorus*, and one or two others; but up to near the end of the first half of the present century scarcely more than a dozen species out of the seventy now known existed in English and Dutch gardens, and of these but two were generally employed for decorative purposes. The late Dean Herbert from 1840 to 1847, and the late M. Gay, of Paris, at about the same time, introduced to cultivation from fifteen to twenty more species, but many of these had been lost, and it remained to the lot of the Rev. H. H. Creve and Mr. H. J. Elwes to re-introduce to our gardens many of Herbert's species and others new to science and cultivation. To many of H. M. Consuls and to the missionary residing in the Levant I am indebted for supplementing my own collection with liberal consignments of many other species, and I believe that we have now not less than fifty out of the seventy species in English gardens.

Comparing the great horticultural results obtained by the earlier cultivators of *C. vernus* and *C. aureus* with our present possession of fifty species, may we not look to the Dutch and Lincolnshire growers to make use of them, and to enrich our gardens in proportion to their means? for many of the newly introduced species are even more decorative than those in general cultivation. The great horticultural importance attaching to the newly introduced species suggests my laying before the Society a brief summary of my observations on the geographical distribution of the genus, to which I shall supplement a few notes on the cultivation of Crocuses.

GEOGRAPHICAL DISTRIBUTION.—The limits of the genus, which is confined to the Old World in the

northern hemisphere, may be stated to be between 9° west and 87° east longitude, between 31° north and 55° north latitude, the main eastern limit being 50° east longitude, and the main northern limit 51° north latitude. The occurrence of *C. alaticus* in the Ala Tagh Mountains, of Central Asia, carries the genus far north-east of the general area of occurrence. *C. Clusii* in Portugal, is the most western species; *C. hymnalis*, in South Palestine, the most southern; and *C. Salzmanni*, the most south-western species at present known. The area of distribution would roughly centre round the Mediterranean and Black Sea coasts, though the genus does not form an essential feature of what is known as the Mediterranean flora, many of them ascending to high ranges of altitude. Looking at the prevalence of species and to general wide distribution, the district including Greece, the Greek Archipelago, and Asia Minor must be looked upon as the metropolis of the genus, for in these regions it forms a more important feature in the flora than it does in the outlying districts to which it extends.

Commencing from the west, the West European and North African district—including Portugal and Spain, the Balearic Islands and France to the west of the Rhone, Morocco and Algeria—possesses ten species, all of which are endemic, excepting *C. vernus*, which occurs sparingly in the Pyrenees and Southern France. The Italian district—including the Swiss and French Alps, Italy as far east as Venice, Sicily, Malta, Sardinia, Corsica, and the neighbouring islands—possesses eleven species, eight of which are endemic. The East European district—east of the longitude of Venice, and as far east as the longitude of Odessa, including Dalmatia, the Danubian Principalities, the Carpathians, Greece, the Ionian Islands, the Greek Archipelago, Crete, and European Turkey—possesses twenty-six species, twelve of which only are endemic. The Circassian and Caspian district, including Southern Russia, east of the longitude of Odessa, the Crimea, Georgia, the region bordering the west coast of the Caspian and North Persia, Kurdistan, Cyprus, and Asia Minor, possesses thirty-two species, seventeen of which are endemic. Syria and Palestine district possesses seven species, five or six of which are endemic. The Central Asia district, west of the Caspian, possesses two species, viz., *C. alaticus*, in the Ala Tagh Mountains, and *C. Korolkowi*, in Turkestan; and these do not occur within the general *Crocus* area.

In the centre of the area of distribution of a genus it is only to be expected that there will occur a greater intermingling of species than on its confines; but in the case of the *Crocus*, the isolation of its species at the extreme eastern and western end of the *Crocus* area is remarkable, the species being notably less transgressive into the centre of the area of distribution than the intermingling of species over wider areas within the centre of distribution. I can offer no sufficient explanation of this fact. The west European species are essentially endemic, and so are the Syrian species. Of the ten West European and North African species, none occur east of the Rhone, *Crocus vernus* excepted; and this within the West European district is found but sparingly. Of the seven Syrian species, nearly all are endemic, except *C. cancellatus*. There is also a remarkable break in the mingling of species at the Adriatic and longitude of Venice, three species only out of a total of sixty-nine, viz., *vernus*, *sativus*, and *biflorus*, and perhaps also *longiflorus*, being common to the districts to the east and to the west of the Adriatic.

Nearly the whole of the species occupy continuous areas, and there is no instance of repeated occurrence in isolated districts separated by wide breaks. The three species most widely distributed are *Crocus vernus*, which has a range in longitude of 23° from the Pyrenees to the Carpathians, and 12° of latitude from Sicily to the Carpathians; *Crocus biflorus* has a wider range of longitude than any other species, extending for 38° from Tuscany

to Georgia; *C. sativus*, in its various forms, extends through 30° of longitude from Southern Italy to Kurdistan, and its distribution is mainly oriental. The same may be said of the species with annulate corolla, which have but one representative, *C. biflorus*, as far west as Italy. Of the division *Involucrati*, species having a basal spathe, thirteen are vernal and seventeen autumn flowering; and of the thirty-eight species of the *Nudiflori*, those having no basal spathe, thirty are vernal and eight autumnal. Of the thirty species of the *Involucrati*, about half occur to the east and half to the west of the Adriatic; and the *Nudiflori*, with two or three exceptions, are all limited to the region east of the Adriatic. Of the entire genus of sixty-nine species, forty-three species are vernal and twenty-six autumnal. Horticulturists who are only familiar with one orange *Crocus*, *C. aureus*, will be glad to know that there are no less than fourteen orange species. They all occur east of the Adriatic; they are all vernal with the exception of one, or perhaps two species; and the whole are now in cultivation with the exception of *C. lazicus*.

GEOGRAPHICAL DISTRIBUTION IN RELATION TO NATURAL AFFINITY.—The grouping geographically of allied species is not general, and the only two notable exceptions present themselves in Western Europe and in Italy. In the West European and North African district there are six or seven autumnal species, viz., *C. nudiflorus*, *C. granatensis*, *C. asturicus*, *C. serotinus*, *C. Salzmanni*, and *C. Clusii*, all closely allied, and forming a compact group; they are all limited to Western Europe and North Africa, where there are no other autumnal species. Two out of the three vernal species, viz., *C. carpetanus* and *C. nevadensis*, are also endemic, and are closely allied, especially in their singular leaf structure, so that with the exception of *C. vernus*, which is sparingly transgressive from the Alps, the whole of the West European and North African species are not only endemic, but both the vernal and the autumnal species respectively range themselves into compact groups. In Italy and the Italian islands and the Alps the endemic vernal species also form a natural group, but they are associated with *C. biflorus* and *C. vernus* of wider range. Beyond these two cases I know of no instance in which the majority of the vernal and the majority of the autumnal species within the same district predominate as natural groups, and as a rule the several types are intermixed. There are, however, many striking cases of the geographical isolation of individual species, the islands of the Mediterranean affording the most conspicuous examples. The remarkable *C. Cambessidisi* is limited to the Balearic Islands. Corsica and Sardinia and the neighbouring islets have two species, *C. corsicus* and *C. minimus*, which do not occur elsewhere. *C. Crewi*, with its singular black anthers, occurs in the island of Syria. *C. cypricus*, the only species with a scarlet filament, is confined to the island of Cyprus, and *C. veneris* to the islands of Cyprus and Crete.

Of insular varieties of species found on the mainland there are several striking examples. *C. adriaticus*, which in Albania is either pure white or white with a purple throat, appears in the neighbouring island of Santa Maura, with a golden yellow throat. *C. vernus* is represented on the Sicilian Mountains by the diminutive *C. siculus*; and *C. Sieberi*, which is self-coloured lilac on the mountains of Greece, appears in Crete, Andros, and some other neighbouring islands, with variegated purple and white or white flowers. Of the passage in colour, from white to blue, in one or two species in their ranging from west to east I have already referred to, and there are other somewhat similar cases of colour variation running as it were parallel through several species within the same district. In Dalmatia there is a general absence of the striping and feathering of species which occur elsewhere with feathered flowers. There are even more marked cases than this of mimetic colouring and of different species associated in the same habitat putting on some identical special form of colouring. Especially remark-

able is the exact identity in colour and markings of the Santa Maura varieties of *C. cancellatus* and *C. hadriaticus*, species which are not nearly allied, and the type colourings of which differ from that of the Santa Maura forms. Another remarkable case is that of the form of *C. cancellatus*, found on the Bithynian Olympus in association with *C. acrius* where it puts on the exact colouring of its companion; moreover, there is a large series of variations in the markings of *C. cancellatus* which are exactly mimetic of the variations in the markings of *C. acrius*, with which it is associated. I do not think that these are the result of hybridisation, for as far as my observations go, I have been unable to detect a wild hybrid *Crocus*; nor do I know of any authenticated case of the production of garden hybrids. It has been suggested that the sterile *C. stellaris*, an old garden plant, the origin of which is unknown, may be a hybrid between *C. aureus* and *C. susianus*; but mere sterility is not sufficient evidence, and it is within my own experience that many wild species tend to sterility after only two or three years' cultivation.

CULTURAL DIRECTIONS for a genus so well known and so easily grown seem almost superfluous, but there are a few points to which it may be convenient to refer in dealing with the *Crocus* as decorative plants. Taking the whole genus of about seventy species, they must be viewed as in continuous succession from the beginning of August till April; and of these it is only the earlier autumnal or the distinctly vernal species that can be relied upon in our climate for open air garden decoration. Although all are hardy, and most of the winter flowering species will flower in the open ground, those that flower in November, December, and January are so liable to injury by frost and rain that they are practically worthless as decorative plants for the open garden. For such, as well as for the less robust and less floriferous species, the protection of a brick pit is necessary. The bottom of this should be well below the level of the ground, and it should be filled up with about 1 foot in depth of fine river sand or sandy loam, the surface of which should be a little below the level of the surface of the ground adjacent to the pit. Proper drainage is essential, but, this being attained, *Crocuses* during their growth delight in a uniformly moist subsoil. It is convenient to separate each species by strips of slate or tiles, which may be buried below the surface, and the corms planted about 3 inches deep. A mulching of rotted Cocoanut fibre or finely sifted peat keeps the surface uniformly moist and prevents the substratum of loam from clogging or caking on the surface. At the time of the maturity of the foliage, which generally takes place about the end of May, water should be withheld and the *Crocus* beds covered up and allowed to get quite dry till the end of July, when a copious watering may be given or the pit exposed to natural rainfall. *Crocuses* are easily multiplied by seed, which should be sown as soon as ripe in July, though germination will not take place till the natural growing period of the species. Seedlings take from two to three years to arrive at maturity, and should be left for the first two years undisturbed in the seed bed, and then taken up and replanted. Of the earlier autumnal species suitable for the open border the following may be enumerated for successional flowering:—

<i>C. Scharofani</i> , orange, early in August.	
<i>vallicola</i> , straw-coloured, late in August and early in September.	
<i>nudiflorus</i> , blue, September.	
<i>pulchellus</i> , lilac, September and October.	
<i>speciosus</i> , blue, September and October.	
<i>iridiflorus</i> , blue, September and October.	
<i>Salzmanni</i>	} lilac or blue, October and November.
<i>asturicus</i>	
<i>Clusii</i>	
<i>cancellatus</i>	} in the late autumn.
<i>Cambessidisi</i>	
<i>hadriaticus</i>	

These are succeeded by a long series of late autumnal, winter, and early vernal species, which are best grown to advantage under the protection of a brick pit. Of the vernal species suitable for

the border, the earliest is *C. Imperati*, flowering in February, followed by

C. susianus, or Cloth of Gold, in February.

biflorus
corsicus
etruscus
suaveolens
versicolor
vernus
Tommasianus
dalmaticus
banaticus
Sieberi and var. *versicolor*
chrysanthus
aureus
sulphureus
sulphureus pallidus and
striatus
stellaris
Olivieri
minimus
Balanæ

Flowering from the end of February to the first week in April.

Of the *Croci* but recently introduced, many more of the vernal species will probably be found suitable for spring garden decoration, but in the above lists I give those only which are more generally known and easily obtainable. Holland, with its rich, light, alluvial soil, and Lincolnshire, with its Trent warp, have been for many generations the sources from which the English market has been supplied with the varieties of the three or four species grown in English gardens. The last five or six years have put us in possession of five-sixths of the known species of the genus, and we must commend them to the care of the Dutch and Lincolnshire bulb growers wherewith to further enrich our collections.

ROYAL BOTANIC.

JUNE 13.

THE second summer exhibition, which took place on Wednesday last, was an extensive one, and on the whole was quite up to the average as regards the quality of the exhibits. The large tent with its picturesque undulating mounds presented a cheerful appearance, though not so brilliant as on the last occasion, when huge masses of Azaleas and Roses lent their gay tints to brighten up the place. The absence, however, of the Azaleas and Roses was amply compensated by an exceptionally large and fine display of Orchids, which were more numerous than ever we have seen them here or at any other exhibition of late years. The central mound, known to *habitués* as the "Orchid bank," was entirely filled with Orchids from amateurs and nurserymen showing in the competing classes. Besides this, one of the semi-circular slopes in the centre of the tent was wholly occupied by a magnificent display of Orchids from Mr. Peacock's garden at Sudbury House, Hammer-smith, which was, as may be imagined, the centre of attraction. Altogether the Orchids were so numerous on this occasion as to almost justify one in calling it an Orchid show; they were as plentiful as they were scanty on the last occasion, when really the season was more favourable for a better show. On the other three central mounds Messrs. Veitch, Williams, and Laing displayed large and interesting groups of choice plants.

STOVE AND GREENHOUSE PLANTS, though not so fine as those at the show a month ago, made a creditable display. The two chief competitors among nurserymen, Messrs. Jackson and Tudgey, who at the last show contested the prizes so keenly, were again the only exhibitors, but this time the order of priority was reversed, for Mr. Tudgey was first in the principal class for twelve plants, and certainly his group was a fine one. He had two huge globular plants of Azaleas, *Criterion* and *magnifica*, the latter quite a mass of white; an *Erica ventricosa magnifica*, perfect in every respect, and some 5 feet through; a gigantic plant, 5 feet through, of *Anthurium Scherzerianum*, and a similarly fine specimen of *Pimelea mirabilis*, *Dracophyllum gracile*, *Clerodendron Balfouri*, two *Ixoras*, and *Erica Cavendishi*, well flowered, and *Allamanda grandiflora*, made up the dozen.

Some extremely fine Heaths were the leading feature in the group from the Kingston Nursery, besides a couple of *Hedaras*, *fuchsoides* and *Tulipifera*, both as fine as could possibly be, and grown as only such skilful cultivators as Mr. Puttick can grow them. The perfect finish of the plants was remarkable, and no less so their freshness and vigour. There was also a grand specimen of *Franciscea calycina major*, which when grown and flowered profusely is uncommonly pretty. In the class for six plants Messrs. Jackson were first, and among the other two groups in the same class from Messrs. B. Peed and J. James there were some fine examples of the Flamingo Plant (*Anthurium Scherzerianum*), but they represented nothing else out of the ordinary run of exhibition plants. The amateurs' class was by no means so well represented as usual; though there was but one class for six plants there were but three competitors, and neither of the groups from these were very remarkable. In Mr. Child's first collection were some well flowered Azaleas, and in the second, from Mr. Rann, were fine specimens of *Aphelexis*, *Hedarama*, and *Erica*.

ORCHIDS.—There were four collections of twelve from amateurs, and among them were some really fine plants, and there was a much smaller percentage of made-up plants than usual. The first collection was shown by Mr. Cobb's gardener (Mr. Catt), Silverdale Lodge, Sydenham, and was a fine one. The most prominent plants were *Epidendrum prismatocarpum*, with eight fine spikes; *Lælia purpurata*, with seventeen flowers; *Thunia Marshallia*, with eight flower-stems; *Odontoglossum vexillarium*, a fine plant; *Cypripedium Veitchi*, with fourteen flowers; *C. Parishii*, with two spikes; *Masdevallia Harryana sanguinea* and *M. Lindeni*, both good plants; *Odontoglossum crispum* and *O. citrosimum*. The second collection was from Mr. Philbrick's garden, and was also a good one. In it were five plants of *Lælia purpurata*, with eighteen flowers on five spikes; *Cypripedium barbatum* superbum, *C. caudatum*, and *C. levigatum*, *Epidendrum vitellinum majus*, and *Cattleya Mossiæ*, smaller plants of *Odontoglossum Roelzii* and *vexillarium*, and *Masdevallia Harryana magnifica*. The third group of twelve, from Mr. Southgate's garden, Streatham, comprised excellent plants of *Cypripedium Stonei*, with seven spikes; *C. Domini*, with six spikes; *Oncidium crispum grandiflorum*, a fine variety; *Cattleya Mossiæ*, with eleven flowers; and a magnificent variety of *C. Mendeli* named *selbornensis*, which had an exceptionally richly marked labellum. In the other collection, from Mr. Little, were specimens of the rare *Vanda Denisoniana*, the new *Dendrobium Dearei*, the true *Cattleya amethystina* under the name of *C. Leopoldi*, *C. Aclandiae* with seven flowers. The best six Orchids from amateurs were shown by Mr. Bell's gardener. These included three fine plants, viz. *Vanda suavis*, with six spikes on two breaks; *Aerides Lobbi*, with two branching spikes, a fine plant; and *A. Fieldingi floribundum*, a plant with two breaks and carrying six spikes, all branching. In Mr. Cobb's second group was a plant of *Dendrobium Falconeri* not often seen, *Thunia Marshallia*, and a dark variety of *Odontoglossum vexillarium*, very beautiful. There were two other collections in the class both representing small, but creditable plants of ordinary kinds. Among nurserymen, Mr. James was first in both the classes for twelve and six plants, and both were uncommonly fine, and particularly the group of six, in which there was a fine plant of *Anguloa Clowesi*, also of *Cattleya Warneri*, fine masses of *C. Mossiæ*, *C. Mendeli*, *Masdevallia Harryana*, and *Dendrobium suavisimum*. Among the dozen plants from Mr. James were the new and rare *Odontoglossum cordatum aureum*, *Cattleya Mendeli* and *Mossiæ* in fine varieties, *Oncidium macranthum*, and *Masdevallia Harryana*. Messrs. Jackson were the other exhibitors among nurserymen, and had some showy masses of *Cattleyas*, *Odontoglossums*, and others.

ORCHIDS shown in the non-competing classes were numerous, the most extensive collection being, as we before remarked, that from Sudbury

House, which was the admiration of everyone, the arrangement being so tasteful. The group consisted for the most part of *Odontoglossum vexillarium*, all profusely flowered specimens, and exhibiting considerable diversity as regards shade of colour. These were placed in large masses. Similarly arranged was a rich assortment of varieties of *Cattleya Mossiæ* and *Mendeli*, while towards the margin were belts of *Odontoglossum crispum*. Interspersed in the background were fine specimens of larger growing Orchids, such as *Anguloa Clowesi*, *Lælia purpurata*, *Sobralia macrantha*, *Lycaste Deppei* and *Skinneri*, and the whole of these flowering plants rose from a verdant carpet of delicate Maiden-hair and other Ferns, the whole forming a charming gathering, and for which Mr. Peacock's gardener (Mr. Vicary) was appropriately awarded a silver-gilt medal. Another large group of Orchids, but less tastefully displayed, came from Mr. Bockett's garden at Stamford Hill; it comprised a large collection of *Odontoglossum crispum* and other species, and a host of varieties of *Cattleya Mossiæ*, which was also shown numerously from Mr. Little's and Mr. Philbrick's collections.

FINE-FOLIAGED PLANTS were, as usual, shown finely by Mr. Rann, who brought the best group of six from Handcross Park, all huge specimens. They were *Cycas revoluta*, *Areca sapida*, *Livistona rotundifolia*, *Croton majesticus* and *angustifolius*, both exceptionally high coloured, and *Gleichenia Mendeli*. This exhibitor also showed the best group of six Palms, having *Pritchardia pacifica*, *Versaffeltia splendida*, *Chamaerops humilis*, *Phoenix tenuis*, *Thrinax elegans*, and *Latania borbonica*, all represented by gigantic specimens in admirable condition. From nurseries the finest group of foliaged plants was that from Mr. James, who had grand examples of *Theophrasta imperialis*, *Cycas revoluta*, *Pandanus Veitchi*, *Cycas circinalis*, *Phormium tenax variegatum*, and *Alocasia macrorhiza variegata*—a good representative selection. There were a few creditable plants among the other groups, but nothing worthy of note.

FERNS were shown in fine style by amateurs. From Mr. Bell's garden at Garbrand Hall, Ewell, Mr. Child brought the winning collection of six, which in every way were perfect specimens. They were *Davallia Mooreana*, nearly 7 feet through; *Microlepia hirta cristata*, of similar dimensions; *Todea superba*, 4 feet through, and in the perfection of health and freshness; *Dicksonia antarctica*, and *Phlebodium aureum*, a huge plant about 6 feet through, with every frond of a bluish gray tint. A superb plant of *Adiantum farleyense* completed the half-dozen plants in this very fine group, which reflected great credit upon the exhibitor. A better or more representative selection could not have been shown, all being first-rate exhibition plants. A grand group of six was also shown by Mr. Rann for the second place. It comprised *Davallia Mooreana*, 7 feet through; *Gleichenia rupestris* and its variety *gigantea*, *Mendeli*, all three huge specimens; *Dicksonia squarrosa* and *D. antarctica*. Neither of the other amateurs' collections were remarkable. In the nurserymen's class the best group, from Mr. Stevens, Putney, contained fine specimens of *Davallia pyxidata*, *Adiantum formosum*, and some vigorous young Tree Ferns.

PELARGONIUMS, from which the exhibition derived a deal of its brightness, were, as usual, shown by the two leading growers, Messrs. Turner and Little, who showed large and admirably flowered specimens in nurserymen's and amateurs' classes of both show and fancy varieties. Zonal varieties were creditably shown also by one or two exhibitors. Begonias were better than we have seen them here for a long time, particularly the fine group from Messrs. Laing, at whose nurseries these flowers are a speciality. This firm was first in the class for a dozen from nurserymen, and a very fine collection they showed, all large and finely flowered specimens. The varieties included such beautiful ones as *Brilliantissima*, *Lothair*, *Mrs. Dr. Duke*, *Purity*, *Mr. Boscawen*, *Sensation*, *Marchioness of Bute*, *Golden Gem*, *No-*

vely, Perfection—a fine selection. Mr. Coppin's collection was also good, likewise that from Mr. Child among amateurs. There were two or three collections of Fuchsias, which, however, were not remarkable.

CUT FLOWERS seemed to be represented more numerous this year than ever. There was quite a bewildering assemblage of boxes and trays containing good, bad, and indifferent specimens. All, however, contributed to the interest of the show, and particular attention seemed to be paid to the collections of cut hardy plants, of which there were some fine examples shown by Messrs. Kelway in the competing classes. Roses were good, but not numerous, Mr. Turner's being the only really good collection of twenty-four trusses, though of course the Rose season has hardly set in yet. There were some admirable *Maréchal Niels* from Mr. Turner, and other exhibitors showed Climbing *Devoniensis*, Adam, Lamarque well, but which were probably cut from sheltered situations. There was a good display of cut Orchid blooms as well as cut flowers of other stove and greenhouse plants, all adding to the extent and attractions of the show. Wild flowers, as usual, were plentiful.

FRUIT on the whole was poorly represented compared with the fine displays that have been seen in previous seasons. There were about half a dozen Pine Apples, some fair examples, but none remarkable. Black Grapes were the best in the Grape classes, and some excellent Black Hamburgs were shown by Messrs. Aslett & Herrin in the class for three bunches, and by Mr. Bates, Twickenham, in the class for the best basket of Black Grapes of any other variety were very poor, except the first prize bunches, which were good examples of Black Prince from Mr. Bolton. Three bunches of Madresfield Court were shown by one exhibitor in the class, but the berries were quite red, and it seemed a pity that such fine bunches should have been sacrificed for the sake of a paltry prize of 10s. The white varieties of Grapes, too, were for the most part green, particularly the Muscats, and there was scarcely a bunch fit for eating of the whole number shown. There were, however, some good examples of Buckland Sweetwater and Foster's Seedling from Messrs. Herrin & Aslett. Peaches were few and Nectarines fewer. Among the Peaches, Alexandra and Early Louise, from Mr. Robins, took the first prize, Bellegarde and Royal George the second, and Noblesse and Royal George the third. Among Nectarines, Pitmaston and Hunt's Tawny were the first two dishes, Elruge and Lord Napier the second, and the same varieties the third. There were but four exhibitors of two dishes of Strawberries; the first, from Mr. Goldsmith, were of James Veitch and Sir Joseph Paxton varieties; Dr. Hogg and Sir Joseph Paxton were second; President and Grosse Sucrée third. Four braces of Melons were shown, the best being fine examples of Scarlet Gem and High Cross Hybrid from Mr. Hopkins. An interesting collection of Cherries, Peaches, and Nectarines was shown by Messrs. Rivers, Sawbridgeworth, consisting chiefly of their new varieties. There was no competitor for the three prizes offered by the Fruiterer's Company for the best collection of English grown fruit open only to market growers.

The miscellaneous class was a large one and the exhibits comprising it were as numerous as those in the competitive classes. Silver-gilt medals were awarded to Messrs. Veitch for a large mixed group of plants including several novelties; to Messrs. Laing & Co. for a group of fine foliage and flowering plants, among the latter tuberous Begonias being the most noteworthy; to Mr. B. S. Williams for a similarly large group, the flowering plants consisting, for the most part, of Orchids, among which were some grand masses of *Cattleya Mossiae*, and others. A large silver medal was also taken by Messrs. Barr & Son for an extensive display of cut hardy flowers, similar to that shown at South Kensington the day previous. Messrs. Hooper took a small silver medal for a fine collection of cut hardy flowers and plants. Bronze medals were awarded to Messrs. Kelway or a large collection of cut blooms of double and

single *Pyrethrums*; to Mr. Hooper, Bath, for collection of cut florists' flowers; to Mr. Salter, Streatham, for fine specimens of *Utricularia montana*; to Messrs. Cannell for a collection of cut flowers of show and fancy *Pelargoniums*; to Messrs. Paul & Son, Cheshunt, for a group of Roses; to Mr. Little for collection of *Cattleya Mossiae* in variety; and likewise to Mr. Heims for a similar group of same Orchid.

Botanical certificates were awarded to

CATTELEYA NOBILIOR, a new species in the way of *C. dolosa*. It is of dwarf growth and bears large flowers of a soft rose-pink, with a large sulphur yellow blotch on the labellum. Shown by Mr. Vicary, gardener to Mr. Peacock, Sudbury House, Hammersmith.

PRITCHARDIA GRANDIS.—The noble leaved new dwarf fan-leaved Palm, fully described recently in THE GARDEN. Shown by Messrs. Veitch.

NEPENTHES EXCELSIOR.—A superb new Pitcher plant in the way of *N. Rafflesiana*, but with pitchers twice the ordinary size, and highly coloured. Exhibited by Mr. B. S. Williams.

CATTELEYA GIGAS SANDERIANA.—A splendid variety remarkable for the large spreading labellum of a rich amethyst grained with white. Shown by Messrs. F. Sander & Co., St. Albans, and Mr. James, Castle Nursery, Lower Norwood.

PHALENOPSIS SPECIOSA.—A new species or variety, similar to *P. Luddemanniana*, but the flowers are more highly coloured and not so distinctly barred. Exhibited by Col. Berkeley.

CATTELEYA WARNERI SUDBURYENSIS.—A magnificent variety with an unusually large labellum of the richest amethyst-purple colour edged with a frilling of white, and also white in the throat. One of the finest forms of this *Cattleya* we have seen. Shown by Mr. Peacock.

ATHYRIUM FILIX-FEMINA KALOTHRIX.—A most elegant variety of the hardy Lady Fern, with the fronds divided into hair-like divisions. Messrs. Veitch.

DENDROBIUM DEAREI.—This beautiful new white-flowered species, described recently in THE GARDEN. Shown by Mr. Little.

SELAGINELLA CANALICULATA.—An elegant species having tall stems with branches springing out at right angles, which makes it very distinct. Messrs. Veitch.

ODONTOGLOSSUM CRISPUM PURPUREO-PUNCTATUM.—An extremely pretty variety, remarkable for the flowers being rather copiously spotted with rosy purple on a white ground. Messrs. F. Sander & Co.

CATTELEYA MENDELII SELBORNENSIS.—A splendid variety, among the finest we have ever seen of Mendel's *Cattleya*. The lip is very richly coloured, and the petals and sepals are of a beautiful rosy purple. Shown by Mr. Salter, gardener to Mr. Southgate, Streatham.

MASDEVALLIA ROSEA.—A new species recently described in THE GARDEN. Shown by Messrs. Veitch.

GYMNOGRAMMA CALOMELANOS GRACILIS.—Differing from the type in having more finely divided fronds, rendering it a very elegant plant. Messrs. Veitch.

The following plants, to which allusion was made in the report of the meeting at South Kensington, were also awarded botanical certificates: *Adiantum Novæ-Caledoniæ*, *Polystichum acrostichoides grandiceps*, shown by Messrs. Birkenhead; *Acer crategifolium variegatum*, *Cyathea microphylla*, *Hydrangea rosea*, *Mimulus radicans*, from Messrs. Veitch.

Floricultural certificates were awarded to the following:—

BEGONIA MRS. FOSTER (double), H. WALTER (single scarlet), MRS. ANSON (single), ORANGE BOVEN (single, orange), MARCHIONESS OF BUTE (single, rose), NOVELTY (large orange-scarlet, single), all splendid varieties of the tuberous-rooted class, and shown by the raisers, Messrs. Laing, Stanstead Park, Forest Hill.

PYRETHRUM COMPACTUM.—A single-flowered variety remarkable for the dwarf growth, being not more than 9 inches or 1 foot high. Mr. Hooper, Bath.

GLOXINIA MIRANDA and *DAIMIO*, both superb new varieties of the erect-flowered type. Raised and exhibited by Messrs. Veitch.

CHRYSANTHEMUM AURORA.—The new double Marguerite, with compact rosette-like heads of bloom of a clear yellow. Messrs. Cannell.

LOBELIA SWANLEY BLUE.—One of the finest bedding varieties that we have seen, the habit being dwarf and compact, and the colour unusually brilliant. Messrs. Cannell.

[A list of awards is given in the advertisement columns.]

KITCHEN GARDEN.

Denham Favourite Tomatoes.—Mr Gilbert sends us some of these, which are very large and firm and in colour rather a dull red. They are extremely well grown, as Mr. Gilbert's Tomatoes always are. How far these various improved varieties of the Tomato surpass the common old red in flavour—the main point—is a question worth considering. These are extremely good in flavour and texture. The price of good Tomatoes, such as Mr. Gilbert's, in Covent Garden ranges from 2s. 6d. to 4s. per pound. With so many good kinds, so many good gardeners, and so many houses and frames not occupied in summer, we ought to be able to grow better supplies of them and at a reasonable rate.

St. Martin's Rhubarb.—My attention has been called to a controversy regarding this Rhubarb. I raised this variety from seed saved from Victoria in 1846 or 1847. The seedling plant (one of about one hundred) for two seasons showed itself to be so much earlier than the other seedlings or any other variety of Rhubarb which I cultivated, that I divided it, and after repeated trials grew it to the entire exclusion of every other variety except the Victoria. The stock which Messrs. Laird & Sinclair purchased was the produce of the one plant just alluded to. I have seen several lots of Rhubarb called St. Martin's which were not true. The variety is very distinct, and I believe one of the best in cultivation, and this I say after an experience of it for thirty-five years.—W. W. JOHNSTONE, *Chester*.

5003.—Flageolet Beans.—These are of the ordinary dwarf type, similar to our so-called French Beans, and are to be found in commerce, though rarely offered under this name in English lists now. It is supposed, though whispered only with bated breath, that the now famous Canadian Wonder Bean is but the old French Red and Crimson Flageolets re-imported from French Canada, and thus converted into a new variety. Without doubt it is a good main crop kind, but it was unfair if it be the Flageolet to give it a new name. In Continental lists that of M. Benary, of Erfurt, for example, we find no fewer than thirty so-called kinds of dwarf Beans, amongst which the crimson-seeded, purple-seeded, and white-seeded Flageolets appear at the low price of 6d. per pound, and there is also a wax Flageolet which has yellow pods, and said to be of delicious flavour. It would be interesting to learn why the term Flageolet is applied to a Kidney Bean.—A. D.

5013.—Potatoes on the same ground in successive years.—Whilst it is a received maxim of Potato culture that it is best to alternate Potatoes with other crops from year to year, yet the exigencies of culture often prevent this from being done. I am perforce compelled to grow Potatoes on the same soil year after year in many parts of the ground, and I find, first, that as a rule the crops are both just as good and sound as when grown in succession to Peas, Beans, or other diverse crops; there are myriads of others who can say the same thing, and probably will say, as I now say, that it matters very little what crop has preceded the Potato, even whether it be Potato or not; the chief point is found in the

state of the soil at the time of planting, and if that be well pulverised, deeply worked, and in good nutritive condition, Potatoes will come as good after Potatoes as after anything else. Who that has seen the robust growth usually made by self-sown plants can doubt that such is the case, for these always come strong, and if left to stand produce large crops of tubers. "F. B." is, however, in doubt as to the effects of the disease upon his Potato crops this year, following as they do in one part Champions that were diseased last year. Now upon such a point it is absolutely impossible to give a positive opinion, not only because all authorities are not quite in accord as to the nature and operation of the disease, but also because it does not follow if the *Peronospora* is of the spreading or sporadic nature usually assigned to it, that plots of ground that adjoin, and on which Potatoes were not grown last year, are not just as much permeated with resting spores now as is the soil in which the Potatoes are planted. The matter is one for actual trial and demonstration, and if "F. B." has ground in which no Potatoes were grown last year planted with the same sorts also, he should presently have conclusive proof that his gardener is either right or wrong.—A. D.

NOTES OF THE WEEK.

ILL-SMELLING FLOWERS.—People should begin to discriminate among flower smells. Even among families supposed to have agreeable odours there are a great many which, in strong doses, are extremely disagreeable and even injurious. At the horticultural meetings at the Linnean Society's rooms the odour was, in some places, almost overpowering owing to the presence of a number of Lilies remarkable for their offensive scent, such as some of the Martagon section.

HORTICULTURAL CLUB.—The monthly meeting and dinner of this club was held on Tuesday last at their rooms, Henrietta Street, Covent Garden, and was numerously attended. The following gentlemen were admitted members: J. H. Mangles, Esq., Valewood, Haslemere; G. Loder, Esq., Floors, Weedon; Dr. Henry Bennet, The Ferns, Weybridge; and Mr. Henry Stevens, Byfleet. It was unanimously voted that a life membership subscription of 10 guineas be given to the Gardeners' Benevolent Institution. Most of those present afterwards attended the meeting of the Royal Horticultural Society at Burlington House.

SCOTTISH PANSY SOCIETY.—The secretary of this Society, Mr. W. Welsh, writes as follows concerning its annual show, which is to be held in the Waverley Market, Edinburgh, on Friday, the 22nd inst. "It is open to anyone to compete, no notice being required. In a late season such as this is English growers ought to be in a better position than those in the north, where the dry season and cold winds have checked the growth of the plants very much. Last year Captain Halford Thompson, from Exeter, came and carried off prizes and certificates, and Miss Owen, from Knockmullen, was also successful; and it would be cheering to see a number of competitors from England."

THE BOTANICAL SOCIETY AND ITS ARRANGEMENTS.—Complaints have come to us of the action of the Royal Botanic Society in altering the date of its evening fête. One lady bought six tickets, and finds them now useless to her, as she has other engagements for the newly-appointed night. Many who come to London at this season are obliged to fix their arrangements beforehand, and arbitrary changes of this sort are a great inconvenience to them. To change the date of the night fête for a personal reason, wholly regardless of the convenience of thousands of other people, whose time and arrangements are equally valuable to them, is unworthy of a public body. The want of backbone is so obvious in the governing bodies of societies, that we wonder naturalists did not take notice of the fact when they classed man as a vertebrate animal. In a circular just issued by the

Society it is stated that "His Serene Highness, the President of the Royal Botanic Society, has, with the consent of the Council, postponed the evening fête from Wednesday, June 27, to Thursday, June 28, to enable himself, Her Royal Highness the Princess Mary, Duchess of Teck, and others to attend the fête." After this it is considerate to add that "tickets issued for the 27th will be available on the 28th."

ENGLISH PLANT NAMES.

SUPERSEDING Latin names for plants has never at any time entered my mind, but I insist on the necessity of an English name for every plant considered worthy of a Latin one. Latin names are current all the world over among gardeners and scientific people generally, and the English names are especially designed to meet the wants of those among us who cannot or will not take the necessary trouble to learn Latin names and their meanings. "T. B." (p. 509) preaches from his old text, "it is all a mistake," and seems quite surprised that his "armour of unassailable facts" was made so little of by me (p. 362). It is quite evident that "T. B." is amongst those who are disappointed because my argument is not "English *v.* Latin," but "Latin and English" combined, but as all reformers have been more or less misunderstood, I suppose I must not complain because "T. B." is among those who misunderstood the basis of my argument for English names. As I have before said, it is the business of botanists, gardeners, and nurserymen to know Latin names for purposes of trade, international or otherwise, but it is not the business of every amateur, and one can scarcely expect the public generally to acquire them; hence for the masses of the people English names are absolutely essential. "T. B." is as ambiguous as ever (p. 509), making his usual assertions, but giving us no good argument against the auxiliary value of English names. At any rate I begin to know that he is totally opposed to the use of English names, which is so much information gained. But did it ever occur to "T. B." that this question of Latin names is mainly confined to the flower garden, for are not all fruit, and vegetables generally known under English names? Again, in the columns of your contemporary, the *Gardeners' Chronicle*, there is a check which I applied to the naming of varietal Orchids in Latin; indeed, on all hands English names are increasing in use and also in usefulness. I suppose "T. B." belongs to the old gloriosa superbissima school, and so prefers to speak of a Golden Holly under its Latin name of *Ilex Aquifolium aureo-variegata*. Can he tell us the Latin for Dell's Beor or British Queen Strawberry? and if so, does the Latin define the variety more correctly than does the English name? Again, is the flavour of a Pine Apple the better because some of us prefer to call it *Ananas sativa*? or are Lentils more nutritious because called *Ervum lens*? Is it not a suggestive fact that all our British trade in timber, oils, and drugs, indeed in plant products of all kinds, is carried on under English names, the plants themselves which furnish some of these products being absolutely unknown in either Latin or English. And yet the best of all arguments in favour of English names for plants is the fact that such names are now more generally used by educated people than ever they were. F. W. B.

The lectures at the evening meetings of the Royal Horticultural Society are somewhat marred by the gentlemen who do not hesitate to deliver themselves of platitudes and trivialities after each discourse. None of these interjections had the slightest interest to the patient audience. In many cases the points to which they call attention are omitted by the reader of the paper from want of time. The remarks addressed in public to the reader of a paper had better be addressed to him alone. The matters to which we allude did not concern what could be classed as discussion as to any important points raised by the lecturer.

OBITUARY.

MR. ALDERMAN CLAY, hon. sec. to the Bury St. Edmunds and West Suffolk Horticultural Society, died suddenly on the 6th inst. It may be said that Mr. Clay's love of horticulture was hereditary. His father loved and grew flowers before him, and also held the office of secretary of the Bury Horticultural Society. Like many others that have grown into goodly fame and influence, it had small beginnings—meetings in upper or lower rooms, sometimes sinking to one or two, and then again rising into fame and popularity—through all these ups and downs Mr. Clay held on to the Society. His love for horticulture was so thorough and sincere, his zeal so hopeful, and his manners so attractive and genial, that he inspired others with his own spirit, and soon succeeded in rallying others around the Society, till under the fostering influence of its late secretary, the Bury Society has achieved a name hardly second to any provincial society in England. The cottage garden branch of the society was also developed to great perfection under the late secretary, who never appeared to higher advantage than pleading the cause of the cottagers or dwelling upon their merits in gardening. The fame of the Bury Society reached its climax when it succeeded in bringing the Royal Horticultural Society of London down to Bury to hold its first provincial show in connection with the Agricultural Society of England. For his labours in connection with this great achievement he received the gold Banksian medal of that Society, the highest award it can make, and was made a 40-guinea life fellow in conjunction with Mr. Fish, of Hardwick. Nor did Mr. Clay's devotion to horticulture hinder his devotion to public business. With the care of a large private business on his hands he was also engaged in various public offices, serving with much credit to himself and satisfaction to all others on most committees relating to town matters, being a member of the Town Council, director of the gas works, a borough magistrate, an alderman, and filling the office of mayor of his native borough four times. The Mayor and the Corporation, representatives of the public bodies and of the horticultural society followed him to the grave, which was strewn with flowers.

D. T. F.

New nursery firm.—We learn that Mr. F. Horsman, who for the past nine years has been manager for the New Plant and Bulb Company, Colchester, has started a new firm under the title of F. Horsman & Co., Plant and Bulb Merchants, Colchester, and at Mark's Tey.

Odontoglossum vexillarium.—Dr. Paterson, Fernfield, Bridge of Allan, sends us two beautiful spikes of this Orchid, showing the extremes of colour that occur in this species. One has flowers of a deep rose, the other blossoms almost white, except a dash of rose-pink in the upper sepals, which gives the flowers a pretty appearance.

Insects (C. C. G.).—See an article on this subject in another column (p. 573).

Transplanting machines (J. St. Y.).—Apply to Mr. Burrows, Pluckley, Kent, or to Mr. Barron, Elvaston Nurseries, Borrowash, Derbyshire.

White Pink (T. Bush).—A very good variety with large, full, pure white flowers, and highly perfumed; quite worth propagating.

Names of plants.—*A. B.*—*Ornus europæa* (tree); we cannot name the variety of *Clematis*.—*C. N. H.*—Double Poet's Narcissus (*N. poeticus fl.-pl.*)—*J. G. K.*—1, *Phyl. lanthus viviparus*; 2, *Iresine Lindenii*; 3, *Begonia ascotensis*; 4, *Oncidium flexuosum*; 5, *Dendrobium suavisissimum*; 6, *Scilla nutans alba*; 7, *Euphorbia corollina*; 8, *Verbascum philomoides*. Please bear in mind our limit is four plants at a time.—*J. Walker.*—*Aubrieta deltoidea*.—*M. C.*—1, *Athyrium Filix-femina cristata*; 2, *Platyloma rotundifolium*.—*E. C.*—*Chlorophytum orchidiastrum*; *Jasminum revolutum*; *Clematis Lucie Lemoine*; *Cereus flagelliformis*.—*C. T.*—*Hemerocallis flava*; *Lilium pyrenaicum*.—*W. J. Watts.*—*Pittosporum Tobira*.—*M. S.*—*Muscari monstrosum*.—*Donna Serafina.*—*Schizostylis coccinea* (a mixture of loam and peat soil).—*W. Forrester.*—1, *Lycastris aromatica*; 2, *Oncidium pulvinatum*; 3, *Stylidium graminifolium*; 4, *Gesneria fulgens*; 5, *Oncidium sphacelatum*.—*W. B.*—*Epidendrum* species.

"This is an Art
Which does mend Nature: change it rather but
THE ART ITSELF IS NATURE."—*Shakespeare.*

A GARDENING DISTRICT.

A FRIEND, travelling in search of the picturesque, writes to us from Evesham as follows: Have you ever investigated this neighbourhood? There is a great deal here that interests one; the valley of the Avon is full of beauties, and the country round Evesham is one big market garden, acres of Strawberries, early Peas, Cabbages, and Asparagus growing under Plum, Cherry, and Pear trees. It must be paying them well, for I see that they are taking in more fields and planting lots of young Asparagus beds. I saw a field with lines of Plum trees, pale green Peas covered with white blossoms, and lines of purple Cabbages growing between them that almost converted me to ribbon bedding, and suggested an essay on the beauty of the useful in gardening. The cottage gardens are very rich in old-fashioned flowers, and I notice a great abundance of yellow Briers all in full blossom. The soil is rich and kindly, and it might be worth a gardener's while to keep an eye to the district. There is a village at the foot of the Cotswolds called Broadway that is noted for its salubrious air and good water and for the number of fine old houses that are left in it; it is only 5 miles from Evesham. A. P.

IVY UNDER TREES.

It is often found difficult to find a suitable plant to grow and cover the ground under trees in pleasure grounds where Grass does not succeed. But Ivy, if skilfully planted, and care be taken to train it properly over the ground the first season or two, will be found to give satisfaction in most cases. Although it may be considered to be a very curious kind of underwood, seeing that it is a climber, it is nevertheless one of the best possible carpets for ground under large trees. Planters should bear in mind that close to the stems of these there can be no moisture for nourishment. Notwithstanding this, however, pits are dug close to the trees, when, as a matter of course, the plants fail. The only way to make a good carpet under large trees, standing singly or in groups, is to make the pits for the plants outside the drip of the spreading branches, and, if possible, clear of the extreme points of the branches; thus situated, the Ivy roots will have the benefit of sun and rain and moisture. Care must, however, be taken to keep the roots free from drip from the points of the branches, for Ivy, like most other plants, is very impatient of drip falling upon its roots. To procure a quick and satisfactory carpet, the Ivy must be planted from 3 feet to 5 feet apart. Make the pits large enough to hold about one or two bushels of fresh loamy soil, enriched with a little rotten manure. After planting and firming the soil well, give each plant a good soaking with water. It will be found more profitable to plant strong, well-rooted plants than weak ones, and plants growing in pots, if required to be planted during the summer months, should be selected. The points of the shoots must be directed inwards, pegging them down until they reach the bole of the tree. In this way a smooth, green carpet will be speedily formed. No matter how barren the ground under the trees, the Ivy will grow and progress rapidly if the roots are provided for in the way just described. Another good effect is, it will kill all weeds as soon as it assumes the lead. When thoroughly established, the points of the young growths will need cutting in to keep it close and compact. Sometimes Barberries are planted at intervals in the Ivy carpet, and with good effect, the yellow flowers contrasting well with the green Ivy leaves underneath the spreading branches of a large deciduous Oak or specimen Cedar. St. John's Wort, when planted close to the edge of the Ivy, forms a good companion to it,

growing dwarf and flowering freely. Butcher's Broom may also be planted with good effect near the edge of the Ivy carpet. It grows in any soil, and in almost any position. W. CHRISTISON.

NOTES.

EDELWEISS, OR BRIDAL EVERLASTING.—Now that the tourist season has commenced, so surely again comes the news of inexperienced mountain climbers falling from rocks up which they have climbed to gather the silvery flower-heads of this alpine weed. Yesterday I read a paragraph relating to a serious accident of this kind, and lamented that people presumably well to do should risk their lives for the sake of a plant as easily grown in gardens as Mignonette or Canterbury Bells. Now is a good time to sow its woolly seeds in a pan of light sandy earth. When the plants are large enough pot them singly in 3-inch pots, using a compost of fibrous loam and broken limestone. Plunge the pots in ashes in a sunny position in the open air, and water when necessary. The strongest of these seedlings will flower the following year, but still stronger and better the year afterwards.

IT is interesting to note that while the tourist is anxious to eradicate the plant in the Swiss Alps, the Bohemian Government are trying to acclimatise it on their mountains.

The acclimatisation of Edelweiss (*Leontopodium alpinum*) in the Bohemian mountains is to be tried, and a special nursery for this precious alpine plant has been established in the Grand Ducal Gardens at Schlackenwerth, in North-Western Bohemia. When sufficiently strong, the young plants will be taken to the Keilberg, one of the peaks of the Erz-Gebirge range which divides Bohemia from Saxony.

In Killarney, we are told, *Trichomanes radicans* is all but as extinct as the Irish elk, thanks to the uprooting energy of the tourist, and now we hear that it is imported from Madeira and the Canary Islands, and "discovered" in Killarney, for all who care to pay for a specimen of "the raal Fur-rn."

THE BIG SCARLET POPPIES.—As raised from seed, it is quite astonishing to note the individuality of these fashionable flowers. From a packet of seed some two years ago we have now in flower several varieties varying in colour from reddish amber to deep crimson-scarlet, with a black blotch at the base of each petal. All who were so fortunate as to see Miss Jekyll's arrangement of hardy blossoms the other night at the Linnean Society's rooms were delighted with the gorgeous beauty of these noble flowers. But it is for outdoor garden effects that they are most valuable grouped with golden and glaucous leaved Funkias, dwarf shrubby plants of *Quercus concordia* (Golden Oak), or planted in bold groups among clumps of *Lastrea Filix-mas*, or other strong growing hardy Ferns and Grasses for contrast. Another way of propagating them is to dig up old-established clumps, break their fleshy roots into pieces, and replant these in good prepared soil.

A NOBLE TOWN TREE.—The Plane tree does so well in most of the London squares, that gardeners and others are not a little surprised to hear that there are towns in England, Scotland, and Ireland where no amount of coaxing will enable it to thrive. What I now wish to say, however, is that a hardier tree with even finer foliage often thrives and forms a noble town tree in positions where the Plane can scarcely be induced to exist. This tree is the large-leaved Maple, *Acer macrophyllum*, long ago introduced from North America, but rarely seen even in the best of town gardens. Everyone fond of deciduous trees should make a note of this one, if they already have it not. There are also two or three "golden Sycamores" well worth attention for gardens, whether in town or country; contrasted with the purple-leaved Hazel or the purple Beech, these golden Sycamores produce effects in the spring quite unattainable by any other tree growth whatever. Acers

generally are far too often neglected by modern tree planters.

ANTHURIUM ANDREANUM.—This plant seems quite as variable in its habit, size, and in the colour of its spathes as is Schertzer's species, and those who are disappointed with it must have obtained pale or crumpled forms. A good variety has bright scarlet spathes, and the spadix is pure waxy white with a yellow tip only, while the spadices of the inferior kinds are wholly yellow. It will be remembered that when this plant was introduced Mr. Brown thought he detected some little differences in the specimens which came under his notice, and we now see that this variety really does exist. Well-grown specimens of the best variety are just now most effective, and the plant contrasts well with Ferns, Palms, Dracenas, and other fine foliaged plants.

THE DARGLE ROSE.—An unknown friend sent me two years ago a wild Rose bush under this name. It grows rapidly and bears large glaucous leaves and single rose-tinted flowers. The most remarkable characteristic of the plant, however, is its large oblong hairy "hips" or fruit, which, being freely produced, render the bush quite ornamental during the autumn months. I never saw the plant before, but I have no doubt it is the kind described by Parkinson at p. 418 of his "Paradisus" as *Rosa pomifera major*, or the Great Apple Rose. If not actually wild, it is here and there naturalised in woods and copses near to where houses formerly stood, and so it is possibly an escape from gardens. Its fruits are so bright and showy, that such a distinct plant must exist here and there in gardens, and I would gladly hear more of its history.

COOL ORCHIDS.—If we are to believe a circular just to hand, a natural check seems to have arisen which promises to stop in some measure the exportation of cool Orchids from abroad. Speaking of *Odontoglossum Pescatorei* and *O. Alexandræ*, we are informed that vast quantities have been thrown into the market of late, and the price is now so reduced that the importers are not making any adequate return. We do not think they will ever be so cheap again, as it cannot pay to get them over. The auction prices are now said to range from 8s. per dozen and upwards according to size. So much for imported scraps, but I remember half a plant of *O. Alexandræ* in flower being sold by auction the other day for something like £40.

HARDY FLOWERS.—The glorious collection of Iris blossoms and of other hardy flowers recently exhibited at London exhibitions by Mr. Barr must have done an incalculable amount of good, thus opening the eyes of country amateurs, and even of professional gardeners, to the wealth of colour and the beauty of form which it is possible to possess wherever there is a garden. Exhibiting hardy plants and cut flowers of them is one way—some think it the best way—of "spreading the light." No Orchids grown at great cost for coal and labour could be more lovely than Mr Barr's bank of Iris flowers, or "cottager's Cattleyas," as a waggish friend persists in calling them.

AN APOLOGY FOR ORCHIDS.—Visitors to the evening meeting at Burlington House the other night must have had a great treat. The main attractions seem to have been the collections of Orchids from Mr. Lee and Sir Trevor Lawrence, and the hardy flowers and plants arranged by Miss Jekyll. Here is an account of the effect from a contemporary: "Most interesting was the contrast between the Orchids in the one room and that of hardy flowers in the other. There was not much attempt at grouping the Orchids, and they were shown by themselves without the aid of Ferns and Palms and other subjects, which, had the object been merely a decorative one, might appropriately have been introduced. Although there was no designed contrast between the two groups of hardy flowers and of Orchids respectively, yet it was apparent that

where bold effects on a large scale with large surroundings are required the hardy plants would carry the day. On the other hand, where beautiful objects are to be seen as it were isolated, there the exquisitely pure colours and delicate gradations of tint of the Orchids would carry all before them, to say nothing of their surpassing scientific interest." Are, then, the colours of the Orchids better than those of the plants of the northern world? I say, decidedly not. There is a range of colour in the Primrose and Auricula a mine in itself. Do we want pure simple colour? What, then, can equal Cardinal Flowers, Evening Primroses, Poppies, Gentians, Pæonies, Daffodils, Phloxes? Where are the wonderful and iridescent blues? Where are the delicate gradations of tint like those among the wondrous Delphiniums? If we come to delicate colour, what in the world surpasses the great Iris family, from the gold and purple companion of the Snowdrop, *I. reticulata*, to the wondrous Japanese Iris in its many coloured large flowers? VERONICA.

TREES AND SHRUBS.

FORMATION OF YOUNG PLANTATIONS.

THERE is perhaps no question at the present time fraught with more importance to the landed proprietor than that of how to make large areas of bare Heather moor and barren peat bog pay. Owners of Heather moors and rugged glens in the north receive fair rents by letting them as deer forests and for grouse shooting; but there are vast tracts of uncultivated land and peat bogs in Great Britain and Ireland which neither contain deer nor grouse, and from which the owners never receive a single penny; and as such lands are capable of producing crops of valuable timber under proper management, I will give a brief outline of my experience in the formation and management of new plantations under such circumstances. Peat bog is so widely different in chemical composition from that of ordinary soil, that for most crops it requires altogether a different mode of preparation and treatment both before and at the time of planting in order to insure success. Peat moss, or bog, as it is called, is composed principally of the remains of dead aquatic plants in an imperfect state of decomposition, rendered so by the quantity of water which it contains, and until such time as this excess of moisture is drained off it is incapable of supporting trees or crops of any kind. The first step to be taken in its improvement, therefore, is to have it thoroughly drained. In forming

MAIN DRAINS, care should be taken to carry them along the margin of the proposed plantation, as in this way they answer the double purpose of a fence and an outlet for the water discharged from the smaller drains within the plantation. If possible, large arterial drains should never be cut within the plantation, as they prove a source of trouble and expense in the formation of roads and the removal of timber. These drains may be cut about 8 feet wide at top, 5 feet deep, and 2 feet wide at bottom. In ordinary workable bog I have had them cut to the above dimensions at the rate of 1s. 10d. and 2s. per perch of $5\frac{1}{2}$ lineal yards. In places where the bog forms a quagmire, and where extra work is required, the cost will be a little more according to the circumstances of the case. The next step to be taken is the

FORMATION OF ROADS. These should be laid off so as not only to be convenient for the removal of timber from the different quarters of the plantation, but also to answer the purpose of shooting roads when the cover is let for game. It is also a matter of importance for their stability, as well as saving expense, that they be laid off in such a way as not to come in contact with any cross drains over which it would be necessary to build bridges, always a difficult and expensive undertaking on boggy ground. As, however, most bogs are tolerably level, I have never found much difficulty in directing the small drains from the interior of the plantation in such a way that they could empty themselves into the main drains without crossing

the roads, thus obviating the use of bridges except at the places of ingress and egress. Suppose, for example, a road has to be formed, 24 feet broad, right through a plantation, say from north to south, and that drains have to be cut on both sides of the road, 3 feet wide at top, 30 inches deep, and 15 inches wide at the bottom, the material excavated must be spread upon the road in such a way as to raise its centre and give it a uniform slope towards the drains. Small drains should then be cut at right angles from the roadside drains on both sides, so that one half would discharge their water into the main drain on the east, and the other into the drain on the west side. In all ordinary cases these small drains may be cut at a distance of about 5 yards asunder, or say about 160 perches per acre, which at 3d. per perch would amount to 40s. per acre for cutting. This work should always be executed at least one year before planting operations are commenced, in order to give the bog time to subside and get firm. The next step is to provide about twenty cartloads of clay or soil per acre to be mixed with the bog at the time of planting. I have generally used a railway, capable of being worked by manual labour, for bringing forward the soil, but in cases where rails cannot be had, the material will require to be carted, and as bog roads need a series of years to dry and become firm before finishing their formation, spread a thick coat of Heather, tree branches, or both on the surface to form a road for the time being. The average cost of carting twenty loads of clay or soil is about 6d. per load if it can be conveniently obtained, which would be equal to 10s. per acre. Then for wheeling the soil from the road, and leaving it in small convenient heaps over the surface of the bog, say 10s. per acre. The cost for opening 3000 pits for the young trees, the quantity allowed for an acre, and distributing the soil, giving each pit its proper proportion, would be 30s., and that of planting an acre 10s. Putting these sums in tabular form, therefore, the following represents the cost of planting an acre of peat bog:—

Proportion for cutting main drain enclosing a	£	s.	d.
20-acre plantation, 12 perch at 2s. ..	1	4	0
Cutting 160 lineal perch small drains at 3d. ..	2	0	0
20 loads clay or soil; per load, 6d. ..	0	10	0
Wheeling soil on to bog ..	0	10	0
Opening 3000 pits for plants, and supplying them with soil ..	1	10	0
2000 2-year seedling 1-year transplanted Scotch Firs at 15s. ..	1	10	0
1000 2-year seedling 1-year transplanted Larch, at 20s. ..	1	0	0
Expense of planting an acre ..	0	10	0
Proportion for erecting bridges and making gates ..	0	4	0
Pulling Heather for road ..	0	2	0
	£9	0	0

The above prices are a fair average of what I have actually paid for the execution of such works by contract, and I have seldom exceeded that price, but often had the work done for less money—a circumstance arising principally from the condition of the bog. In autumn the pits should be opened for the young trees; the clay or soil should be divided equally amongst them, and allowed to lie on the edge of the pits till spring, by which means it will be much improved through the effects of the weather. Young trees should never be planted in cold, deep bog land in autumn or winter, as the peat has a destructive influence on the roots, and often kills the plants altogether before the growing season commences. I have always planted bog lands with most success in April. J. B. WEBSTER.

Magnolia Campbelli.—I have observed in some late numbers of THE GARDEN that it has been asserted that this *Magnolia* has been known to flower in several gardens in the neighbourhood of Pallanza, on the Lago Maggiore. This I believe to be a mistake. I have made inquiry at the Messrs. Robelli, at the Gardens at S. Remigio, and of the gardener at this villa, and learn from all that the *Magnolia* supposed at one time to be *M. Camp-*

belli is in truth *M. Lenné*. I may mention that there is just now in nearly all the gardens around the lake a most glorious *Magnolia* in blossom—*M. macrophylla*. Some of the leaves I have measured were 23 inches long by $8\frac{1}{2}$ inches wide. The blossom, of a creamy white, is as large as that of *M. grandiflora* and nearly as fragrant, having a large blotch of dark reddish purple at the base of each petal, reminding one of the flower of the Gum Cistus on a very gigantic scale.—G. M. N.

GOLDEN CONIFERS.

A FEW of these scattered through the foreground of a shrubbery gives an air of refinement and dressiness, if I may so term it, to a place. They are also useful in every kind of formal gardening. The majority of them are hardier than the common Laurel, and they seldom get too large for their situations. One or two of the *Arbor-vitæ* are rather tender; at least, they die off in a most unaccountable manner sometimes when a cold spring follows a mild winter. I have just been told of the death of a number of handsome plants of *Thuja aurea* which were thirty years old, and consequently highly prized, and they occupied positions in an Italian garden as "match plants"—a circumstance which has rendered their sudden failure more annoying. *Biota elegantissima* is also rather tender. A good many dead sprays have had to be cut from amongst the new growth this spring, which I attribute to the cold winds of March when the sap was rising. *Thuja sempervirens* is an improvement upon *T. aurea*, being brighter in colour and retaining its bright golden hue longer, but otherwise it possesses the same characteristics. Golden Yews, both English and Irish, are very hardy and most useful and telling in a foreground, or occupying conspicuous positions anywhere, their changing tints in spring and summer being very effective. I omitted to mention, when speaking of the *Arbor-vitæ*, that *Thuja Vervaeana* is a valuable plant, retaining its golden tint well into the winter. But some of the best and brightest of golden conifers must be sought among the Cypresses. Several very elegant varieties have been obtained from the Lawson Cypress, *C. L. elegantissima* and *C. L. lutea* being very effective. Quite a number of golden forms have also been found among the Cypresses from Japan, *Retinospora obtusa*, *gracilis aurea*, and *R. plumosa aurea* being good, distinct, and useful varieties. E. H.

BARBERRIES AND CORN MILDEW.

I SEND you branches of a plant known in our district by the name of Pipperidge, which fifty years ago was very common in our hedgerows. But farmers got the idea that this plant was the cause of the blight in Wheat, and so fully were they impressed with this notion, that they had it rooted up from their farms, and now there are but very few remaining in this district. The old women doctors of sixty or seventy years ago used it to cure jaundice, and it was said to be the only remedy for that complaint. You will notice that under the bark it is a bright yellow, and that the taste of the wood is quite bitter, while the leaves are sour, and country boys eat them freely. It would be very interesting to us in this locality to have your opinion as to the former statement or any suggestions bearing upon it. You will observe the thorns on the shoots grow downwards, while the foliage is rather pretty. I would further observe that in the locality where this plant grows, fields of Wheat are always more or less blighted.—JAMES LINGLEY, *Broadway Bacton, near Stowmarket.*

** It is a curious fact, apparently overlooked by our correspondent, that the Barberry branches sent to us were badly attacked by the orange-coloured Barberry blight (*Æcidium berberidis*), and it would be interesting if our correspondent would tell us whether the Suffolk Corn fields have been freer from Corn mildew since the farmers rooted up the Barberries fifty years ago. The opinion accepted by many botanists is that the fungus of the Barberry is an early condition of

the fungus of Corn mildew, and that when the spores or seeds of the Barberry fungus are blown over young Wheat plants they grow and cause the orange (at length black) fungus pustules of diseased Corn. This idea, however, is not accepted by all observers, and Dr. Cooke, one of our foremost fungologists, has expressed a strong opinion against its probability.—W. G. S.

Pruning over-grown Lilacs.—This is the best season to cut out with the saw any large unwieldy limbs of Lilac which are becoming unsightly. They should be cut back so that the young growth hides the stump. The outline of large overgrown shrubs may be much improved in this way, and by doing the work immediately after flowering there will be no loss of effectiveness, as the young shoots will gather strength enough to flower next year. Charles X. is a good Lilac, and so is the old white.—E. H.

Picea Pinsapo.—There is a special beauty about all trees in spring and early summer; but there is more character about some trees than others, and *Picea Pinsapo* is one of those which attract attention at this season owing to its handsome new growth as well as for its perfect outline and regularity. For a small suburban or country lawn no better tree could be found than this, and it rarely fails to grow in a satisfactory manner on well-drained soils. In its young state sometimes it may require a little help in the way of pruning into proper shape, but once get the plant fairly balanced and its progress is regular and rapid.—E. H.

Lichens on Thorn.—I enclose some Lichens, of which I find a large crop on the wood of various scarlet Thorns. The trees, rather large ones, do not grow or flower well. One of them, a double red, seems to be very much affected. Is there anything that will check the growth of this Lichen? I fear it may be the same as that which is destroying many trees at a place in this neighbourhood where the Lichen is hanging in clusters on Oaks and Firs. The soil there is near a river and clayey, whereas the soil here is limestone.—M. L. V., *Curragh Chase*.

* * We refer you to the answers given in THE GARDEN (pp. 149 and 190) concerning Lichens on trees, but perhaps some readers who have been troubled in the same way may throw further light on the subject.—E.D.

"Weigela rosea var. amabilis as a lawn shrub.—As usually seen, cribbed, cabined, confined, and 'knived' in the shrubby border, the *Weigela* fails to show what it is capable of, or anything approaching its floral beauty and fine effect at this season when grown singly on grass and allowed to develop itself freely and assume its natural habit. An admirable exemplification of what is here advanced is afforded by a specimen on grass at the College Botanic Garden, Ball's Bridge, which could not fail to challenge the admiration of even the most indifferent. The symmetrical aspect of the mass and its wealth of rosy tinted and gracefully curving wreaths, in contrast with the greensward which forms the setting, made this the summer gem of the garden's outdoor beauties."—*Irish Farmers' Gazette*.

* * We recently saw the specimen in question, which is about 8 feet in height by 12 feet to 15 feet in diameter, its graceful wreaths of deep rosy flowers being a yard or more in length, the lowermost quite sweeping the turf. Mr. Balfie's note fully bears out what we have ever urged against the "choke-muddle" shrubby border.—E.D.

Aster alpinus (the alpine Aster).—"This plant (see p. 533) is very easily grown in any soil." I wish it were so, for it is not only the earliest, but perhaps the handsomest of perennial Asters. I have, however, tried every position I can command and every combination of soil, and have got the plant, both the purple and the white form, from several sources, and yet it is a total failure. It lives, but it never flowers at all. It is not the climate, for it does well a few miles off at

Chester, and, as I said, I have done all I can to please it by modifications of loam, peat, leaf-mould, sand, lime, &c., but it continues to be one of those unaccountable failures in hardy plant cultivation which all gardeners meet with.—C. WOLLEY DOD, *Edge Hall, Malpas*.

THE STANSTEAD PARK BEGONIAS.

THERE is perhaps no class of plants in which such rapid improvement has been made as in the tuberous-rooted Begonias now so popular as garden plants. It seems but yesterday, so to speak, since the parents of the race, viz., *B. boliviensis*, *Veitchi*, *Pearci*, and *roosea*, were introduced, and yet the descendants of these species are almost innumerable and so altered in character, that the pure and simple types from which they originally sprang seem to have become lost in obscurity. A visit to Messrs. Laing's Stanstead Park Nursery, Forest Hill, the head-quarters of Begonias in this country, shows how fast the march of improvement is progressing. Here the great speciality at this season is Begonias, which may be seen in enormous quantities—in houses, pits, and frames, as well as in the open ground in thousands. The chief bulk, however, of the flowering specimens, some of which are nearly a yard through, are in one capacious show house, a new span-roofed structure 100 feet long by 20 feet in width, having a broad central stage for the large specimens, and narrower marginal stages for smaller plants. Just now this house presents a brilliant appearance, for each of the hundreds of plants contained therein is profusely furnished with bloom, varying in colour from the purest whites to the deepest crimsons with well-nigh every intermediate shade, besides various tints of yellow. The effect of the crowded stages, too, is considerably enhanced by the long lines of plants in baskets suspended beneath the ridge of the house. These show how suitable some varieties of tuberous Begonias are for hanging in conservatories and greenhouses, or for growing as vase and pedestal plants. The collection here numbers some 200 named varieties, all of which are more or less distinct, either in size of flower, habit of growth, or shade of colour. Every year, however, there is a weeding out of the inferior varieties as new ones are raised to supplant them. For the past two or three years one would have thought that the climax of perfection had been attained as regards these Begonias, but every season seems to bring with it novelties in abundance, surpassing the older varieties in some point or other. This year the novelties in this collection number about half a hundred, and, singularly enough, about two-thirds of these are double-flowered sorts, a fact which seems to indicate that raisers are turning their attention specially to doubles now that such a high degree of perfection has been attained amongst single kinds. Several of these

NEW DOUBLE varieties have been exhibited in London this season, and besides being much admired have been awarded certificates of merit. Of the new doubles in flower we made notes of the following: One of the very finest is Prince of Wales, which has a vigorous constitution and bears enormous flowers, perfectly double, making a compact rosette some 3 inches or 4 inches across, of a vivid crimson colour. A fitting companion to this excellent sort is a double white named Princess of Wales. This is considered to be the best double white yet raised, and unlike the others possesses a strong constitution and is a free flowerer. Canary Bird, with rosetted blooms of a soft canary-yellow, is one of the gems among the doubles, and is unquestionably the best of the very few double yellows yet produced. This was much admired at the first summer show at the Regent's Park. Mrs. Foster is a splendid double of a bright scarlet, and another, called Dr. Duke, is a dangerous rival to the Prince of Wales as regards size and vividness of tint, and, like the Prince, too, it has a fine constitution. The variety named Queen of the Doubles we so much admired last year, and of which we gave a woodcut illustration, is in great beauty,

and though it is surrounded by a crowd of newer kinds, it stands unique as regards the rosebud-like form of the half-expanded blooms, the colour of which is a bright cherry-red. It is also a freer flowerer than many of the doubles. Robin Adair has *Camellia*-shaped flowers of a glowing carmine-crimson. Achilles, one of the Marie Bouchet type, with saw-edged petals, is a fine acquisition, the flowers being very large and of a bright crimson-red. Davisi fl.-pl. *superba* is the long name of perhaps the finest of the dwarf growing class, the flowers being very large and of the richest crimson imaginable. It has, moreover, a free-flowering tendency, but does not possess the vigour of the other class. The original double Davisi is a fine variety, a fair substitute for the choicer and rarer form. Other new double varieties of great promise are Sir Garnet, Hercules, Robert Burns, John T. Poë, Diana, Ada, Clarinda, Mrs. Macfarlane, Rosina, Mrs. Ludlam, Lord Beaconsfield, and Agnes Sorrel. These are a few of the newer kinds in the collection, but in praising these there is no need to speak disparagingly of the finest of the older sorts, which are now established favourites, and will probably not be eclipsed. Among these are such as William Bealby, scarlet; Glory of Stanstead, rose, whitish centre; Fulgorant, with distinct deep crimson flowers; Duchesse de Cambaceres, excellent for basket culture; Comtesse Horace de Choiseul, Madame Comesse, Marie Bouchet, and several others of Messrs. Laing's collection of doubles, which numbers upwards of sixty varieties. There is also a large number of unnamed seedlings which daily unfold their new blossoms; and on the day of our visit the advent of an orange-red double seemed a surprise to all.

THE SINGLE VARIETIES show a corresponding improvement, though the number of this season's novelties is not so high as usual. Among pure whites Mrs. Laing has been supplanted by a novelty named Snowflake, now the finest white, though probably it will only maintain that position for a short season from what we learn from Messrs. Laing, whose great aim is to improve the white and yellow sorts. Snowflake has large, bold flowers, fully a third larger than those of Mrs. Laing, and are of purer whiteness and of better form, the petals being rounded and of firm, wax-like texture. It has also an excellent style of growth. Reine Blanche, one of the older whites, is still a favourite on account of its dwarf habit of growth. Alba floribunda, also, is still a good white. Among yellows the greatest acquisition has been Golden Gem, considered to be the finest of its colour yet raised. It is remarkable for its large rounded flowers, which are of a clear chrome-yellow, also for its erect sturdy growth and handsomely mottled foliage. Sulphur Queen is a pretty sort, but the yellow is not of a decided tone. The scarlets, reds, and vermillions predominate among new singles, though there are some admirable pink and rose sorts, notably Marchioness of Bute, which has been so much admired this year at the shows, and so captivated the judges as to induce them to distinguish it by a certificate of merit. If not "magnificent and with immense blooms," as the catalogue has it, it is certainly extremely pretty, and the flowers surpass other sorts of the same colour; in fact, it may be regarded as the best of its colour. Madame Stella is similar, but deeper in tone, and also first-rate; and so is Nymph, which is of a delicate rosy pink, or rather white edged with pink. Lady Brooke is justly classed as extra fine; its colour is somewhat novel, being of a sort of violet-magenta, while the flowers are large and of excellent form. Madame Laing, apparently of Continental origin, is a fine acquisition, the flowers being of bright vermillion and perfect in other points. As regards perfection of habit of growth, Novelty is second to none. It is of dwarf, sturdy growth, and the flowers are very large and of a resplendent orange-scarlet. It was one of the most admired in the fine group of twelve shown at the Regent's Park last week by Messrs. Laing. H. Walter was another splendid sort in the group, and like Novelty, Marchioness of Bute and Mrs. Anson were considered worthy of certificates of merit. Crimson Perfection was finely in bloom, so that two

could well judge of its excellent qualities. It is certainly the perfection of all the bright crimsons, eclipsing even such sorts as Stanstead Rival and Consul Darlington, which have hitherto been considered the best in their colours. Arthur Soames has for a long time been ranked as the finest deep crimson, but this even is surpassed now by Black Douglas, which has very large fine-shaped blooms of an intensely deep crimson. A splendid sort, named in compliment to Mr. Boscawen, is a great favourite wherever it has been exhibited. It has a fine habit of growth, and carries very large flowers of a vivid scarlet. The Czar is remarkable for its rich deep crimson flowers, which, moreover, possess unusual size and good shape. The orange colours, very limited among these Begonias, is best represented by the new Orange Boven, which is a great improvement on any other of the same colour, the flowers being large and round and the colour bright and decided. Among the other kinds in fine flowering condition we made note of the following as being uncommonly fine: Lady Hume Campbell, delicate rose, excellent for growing in hanging baskets or in vases or for pedestals; Magenta Queen, Mrs. Robert Whyte, J. H. Laing, Exoniensis (very fine), Edith Box, Royal Standard, Stanstead Rival, Sir Trevor Lawrence, and Maude Churchill. Among the dwarf Davisi race Commodore Foot is one of the finest, and is an exquisite little plant for many purposes for which the larger varieties are not suitable.

OPEN-AIR PLANTS.—There is no better season than the present to see this grand collection of Begonias so far as regards the plants under glass, but in the course of a few weeks there will be a fine display of Begonias in the open air, for, as has been stated, there are several thousands planted out in open borders, chiefly seedling plants for trial. Open-air culture is generally very successful here. Some of the beds, especially those for the choice named varieties, are raised above the level, so as to ensure perfect drainage, and also to enable the soil to become warmed. The soil is rich and friable, and a mulching is usually given in summer. A partially exposed position is selected, usually one which affords the best shelter against high winds from the south-west. These beds present a bright appearance during July, August, and September. For the bulk of the seedlings, which are planted out on a large scale, drills are made in light, rich soil, and the plants placed about a foot asunder, and so left to flower, care being taken, of course, to secure any that give promise of developing into superior varieties. W. G.

NOTES FROM ST. GEORGE'S HILL.

STANDARD RHODODENDRONS.—Some large, handsome specimens bearing hundreds of trusses of bloom, and which stand in conspicuous positions on the Grass in Admiral Egerton's garden, afford ample proof of the value of this showy plant when grown as a standard. There is much variety of form as well as of colour amongst Rhododendrons, scarcely two kinds being identical as regards habit of growth, shape, and hue of foliage, and in no way are these differences so well shown as when the plants are on clear stems and in isolated positions. Crowded together in beds or in shrubberies, this fine evergreen loses much of its individualism, but placed alone, where its outline is fully displayed, and where it has ample breathing space, it forms one of the noblest and most striking ornaments of our gardens. The gardener (Mr. Rose) informs me that the trees above alluded to have been planted about 13 years, and that no special preparation of the soil was made for them, the natural staple being light and poor, a fact which shows that the Rhododendron is of a more accommodating character than is generally supposed.

LITHOSPERMUM PROSTRATUM.—Many of our most beautiful hardy flowers demand much cultural care to bring them to anything like perfection, but here we have one of exceptional beauty whose needs are certainly of the most meagre description. Give it a free soil and an open, sunny situation, and it will increase yearly

in luxuriance and beauty. Growing here in the shrubby borders in light sandy soil are specimens covering a square yard or more of ground and laden with flowers, which in their deep rich tint rival those of the Gentian. The true worth of this hardy flower can only be properly estimated when it counts its existence by years; small specimens do not convey a fair idea of its beauty and decorative value.

WALL ROSES.—Blooming finely on the south front of the house are large specimens of Gloire de Dijon and Céline Forestier, and which for some weeks past, in spite of cold nights and drying winds, have yielded abundance of good flowers. The good qualities of the Gloire de Dijon are too well known to need recapitulation, but those of Céline Forestier have never, I think, been so prominently brought before the notice of your readers as they should be. It is a vigorous, free-flowering Rose, thriving well either as a standard, on a wall, for which, owing to its semi-evergreen character, it is especially well fitted, or under glass. Grown in good rich soil or well fed during the summer, one may always cut a bud from it, and such Roses as these are just what should be cherished, especially by those who have not much space to devote to the queen of flowers. It is not the quantity at one time, but a succession of bloom all through the summer and autumn that is desired by many, and this under liberal culture both Gloire de Dijon and Céline Forestier will give.

CAPE PONDWEED.—This fragrant little aquatic flourishes in a basin in the open air. The plants are grown in pots, which are about a foot under the water; but there is no doubt that where convenience for so doing exists it will grow more strongly planted out. I do not think it requires any great depth of soil, but the roots should be enabled to extend laterally. In any case anyone having a tank, pond, or fountain in the open air may, even at this early season, enjoy the delightful, though powerful, odour of what has been appropriately named the Water Hawthorn.

ORIENTAL POPPIES.—Scattered amongst thinly-planted Rhododendrons are large plants of this gorgeous scarlet Poppy, which, raising its flower-heads above the evergreen foliage, affords a most striking and welcome contrast. They are mostly on a sloping bank, and are thus seen to the greatest advantage; moreover, the position ensures vigour and longevity, for this Poppy certainly likes good drainage; drought it seems to fear but little. Therefore it is a good plant for sandy parching soil, mounds, or banks, associating well with the Wallflower and the Antirrhinum, both them plants which dread cold in combination with stagnant moisture, but which rejoice in the full glare of the summer sun.

EUONYMUS RADICANS.—I am sure your readers would be pleased with the manner in which Mr. Rose has employed this little variegated shrub in the flower garden here. All the flower beds on the lawn are edged with it, and as these edgings have been planted some years they have now developed into miniature walls of foliage, charming by their constant and clear variegation, and the contrast they afford to the green turf and the summer occupants of the parterre. Even the most prejudiced against variegated plants would find a delight in the Euonymus thus employed, and I advise all who wish for variety in the flower garden to make a note of it. Winter and summer it is bright and cheerful looking, perhaps most so when colour and beauty in the pleasure garden are at their lowest ebb—at any rate, relieved from the "embarrassment of riches" which prevails more or less in the summer time, one notes its brightness better when there is little but the varying hues of evergreen foliage to adorn our gardens and attract attention.

COLUMBINES.—Few things have the power to impart informality to a border of hardy flowers better than Columbines, and when, as here, they sow themselves naturally, they add thereto an element of picturesque confusion which must please all who love to see Nature's arrangements imitated in the garden. I always think the time of the Columbines marks, like that of the Daffodils,

a distinct epoch in the season of hardy flowers, and when they die away nothing which comes after can quite take their place. Four long borders running the whole length of the kitchen garden are alive with Columbines just now—a pretty sight, varying as they do so much in colour and even in form. J. C. B.

OBSERVATIONS ON SEED SOWING.*

ALL who have been occupied with plant raising, and especially from exotic seeds, as I have been for about thirty years, must have had their experience often grievously tried, and their patience in the end worn out altogether by utter failure. Certain tribes have earned a worse reputation than others in this respect; of these the Ranunculaceæ, as first in botanical arrangement, must have the precedence. So early as the year 1850 I had seeds presented to me by a friend from a lofty mountain range in New Zealand, and therefore certain to prove hardy here; the only name then given me was

THE SHEPHERD'S LILY, which Sir Joseph (then Dr.) Hooker, on being applied to, informed me was Ranunculus lyalli, one of the finest things in New Zealand. Of course the seeds were sown, and all care bestowed upon them. I gave them ample time, as I thought, to vegetate; but the result was a total failure. Years afterwards I had repeated transmissions of these seeds, and had ultimately the good fortune to receive from a correspondent in Dunedin two living plants, sent, with all care, packed up in a Wardian case; but, like many other rare things so transmitted, the finer fibrous roots had given way from the tubers, no fresh ones were emitted, and after a time both roots died. Subsequently to this I received and repeatedly sowed imported seed, and from these I two or three years ago raised plants, of which I have now two that have stood in the open border for two winters. I have no record of the exact time they took to vegetate; so far as I remember, it was about two years. I was much more precise with the following. On receipt from New Zealand of a fresh supply of very ripe and fresh seeds, I sowed them on February 16, 1878, and they vegetated in April, 1881, after lying upwards of three years. My next successful experiment in this tribe—and that, too, after failures stretching over more than a dozen years—was with a not less rare and striking species, viz.:—

RANUNCULUS GUZMANNI, a species which, so far as I am aware, was never before introduced into this country, or even into Europe. I may therefore be pardoned if I give a short account of it from Weddell's "Chloris Andina." "This Ranunculus," he says, "is as remarkable for its port as for the enormous development of its flower. The flower as shown in my specimen—but I cannot say whether it may not be from the pressure in effecting dessication—was of the exact size of 10½ centimetres in diameter." And in the account he goes on to assert that another flower had been found, which, with its appendages, was of a diameter of 15 centimetres. There appear to be two forms of this R. Guzmanni, one having blooms, yellow streaked with red, and the other with greenish yellow flowers. The seeds from which I raised my plant (for I have only one) is the latter variety. It is found growing in the Cordillera of the Andes of the equator, at the verge and "sometimes in the midst of snow." The seeds of both forms were collected and sent to me by Professor Padre Sodiro, of Quito, in March, 1877; the species from which I have raised the plant being labelled R. Guzmanni, sp. floribus late flavis magnis var. valde rara, mili reperta. The seeds were sown by me on March 2, 1877, and vegetated in September, 1881, thus taking four years and six months to vegetate. The plant has grown rapidly, and now shows a diameter of 10 inches over the pot it grows in. It is somewhat singular to remark that, while the R. lyalli found growing in New Zealand at a height of 6000 feet or 7000 feet should take three and a-half years to vegetate,

* A paper read before the Scottish Horticultural Association by Mr. Isaac Anderson-Henry.

this species of *R. Guzmanii*, found on the Andes at 13,000 feet, should take four and a half years to vegetate. Can the elevations and severity of the climate from which they respectively come account for the differences in the periods of their vegetation? I have still another instance of obstinate vegetation in this genus to offer. I had from Dr. Curl, of Wellington, Northern Island of New Zealand, seeds of a species got, I believe, from the mountain ranges, which I sowed on January 29, 1878. It vegetated in September, 1881, thus having lain dormant for three and a half years. Having got it without name, I can say nothing about its character, but the foliage is distinct and peculiar. The seeds were small, but the seeds of *R. Guzmanii* were not large. On looking at authorities, I find that several species are found at above 13,000 feet on the same Cordillera, e.g., *R. nubigenus*, *R. premorsus*, *R. Raimondi*, some of which it resembles in the descriptions given, though I cannot vouch for it being either. After the *Ranunculaceæ* some, not all, of

THE PRIMULACEÆ claim attention for their slowness to vegetate. Many gardeners are now familiar with the obduracy of the seeds of *Primula japonica*, which rarely stir till they have lain for a whole year. This, it will be remembered, is a species having a whorled scape. It is a crimson flowered plant, but I have a white variety with a pink eye, by far the handsomer of the two. I have just got seeds through a friend in Germany from "the Orient," with the name of *Primula Teaskeana*, said to be one of the finest of the tribe, also a whorled species which likewise takes a year to come up. Whether *Primula purpurea* of Royle, also a whorl-stemmed species, takes the same time to germinate, I am not aware. It is for the ingenious inquirer to find out the cause or *rationale* of this peculiarity in this verticillate form. It looks, then, as if the plants having whorled stems in the *Primulaceæ* are slow to vegetate. May it not be worth enquiry whether this habit so manifests itself in other genera having whorled stems?

THE GENTIANACEÆ are also proverbially slow—at least such has been my experience among imported species, of which many years ago I had seeds of some of the finest kinds of the genus from the Andes. And among these I had seeds of one lovely species, which I was most anxious to succeed with. This was *Gentiana Jamesoni*, named in compliment to my correspondent, Professor Jameson, of Quito; and it, too, was a verticillate species with an umbel of scarlet bells at the top. There is another species which I never possessed, by name *Gentiana verticillata*, whose seeds might form a good test. I can speak no further from my own experience, but I would earnestly suggest to those willing to make the experiment to make trial of seeds of any verticillated plants they may possess to find how far the same characteristic holds. It may be further tested by sowing the ripe seeds of the several whorls separately, for some of these may take longer and some a shorter period to germinate. I might here go into a long list of exotic things, especially of those sent to me from

THE ANDES OF QUITO, in raising which I wholly failed, greatly owing to their intractability in vegetating, of which I may particularise the following as yet well worth collecting and transmitting to this country: (1) Various *Castillejas*; (2) various *Thibaudias*, including the allied *Macleanias*; (3) many *Calceolarias*, which, with fresh seeds, are manageable, but with not a few of which I did succeed; (4) *Chuquiraga insignis*; (5) many *Gentians*, especially *G. Jamesoni*, already referred to; *G. sedifolia*, one of the gems of the genus; *G. rupicola*, &c., to which may be added *G. cernua*, having yellow flowers, striated with red; and *G. gracilis*, having a white corolla streaked with violet lines. Another gem, of which I had seeds sent me repeatedly from the same lofty Andes, was (6) *Eccelemocarpus longiflorus*. The seeds were not unlike those of *Calampelis scaber*; but though I kept them sown for years I did not raise one. It is a beautiful flower, and from its great elevation of 12,000 feet it cannot fail to be hardy. The

flower is tubular, about 3 inches long, half-inch thick, and orange coloured; (7) *Sidapichinchensis*, which, from its dwarf habit, its lovely blue flowers, and its station at a height of from 14,000 feet to 15,000 feet on the Cordillera, is one of the most desirable of alpine. I got and sowed it repeatedly, and the same with *Sida phyllanthus*, another beauty; but I also failed with it. But I must pass over numerous failures with seeds of rare plants which I had from the same favoured ranges of the Andes, to notice two of the grandest things remaining yet to be recovered from that region, namely,

TACSONIA JAMESONI and *Tacsonia Mariae*. About the first I had some correspondence with Dr. Masters, who urged me to inquire after it, with a view, if possible, to recover it. After some correspondence, I did succeed in finding out the only locality where it ever had been found. It has a bold and a very grand flower, unlike any other ever known in the genus. Dr. Masters sent me a sketch of it from a dried specimen, which showed that it amply deserved the high encomium he paid it. But my correspondent, who went to the forest, found only one plant, and failed to get a sound seed from it, the seed having been destroyed by insects. *Tacsonia Mariae* is a not less notable species, and perhaps in its native state the loveliest of its tribe, the flowers, unlike any yet shown in this country, specific or hybrid, being large and of the intensest blue. I have before me a Latin description, one page and a-half of print, drawn up by my correspondent, for some time professor of botany in Quito, who being also a priest, dedicated the plant to the Virgin Mary, whose name it bears. Of neither of these plants did I ever receive seeds. A revolution breaking out in the State, my correspondent, Padre Sodiro, was obliged to quit his professorship and pursuit after plants, and confine himself to his religious avocations. All these Andean plants, above enumerated, being of interesting character, beautiful in species, and for the most part hardy, are well worth being yet sought after and introduced into this country, which none of them, so far as I know, have yet reached alive. I have yet said nothing on

HOW TO SOW THE SEED, though this is a very important thing. A third of fine loam, a third of peat, and a third of silver sand, with a little of pulverised leaf-mould, make a good compost. Drain and fill your pot, and when full to a quarter of an inch press down with a flat-bottomed tin to make a smooth surface; then if your seeds be small, say of *Begonias*, *Heaths*, or the like, sift with a fine wire sieve a little sandy compost, on which sow your fine seeds, and then, without covering them, press down with your smooth-bottomed tin; you will find by the pressure they will be sufficiently covered. Larger seeds, such as *Delphiniums*, *Columbines*, or the like, may be covered by the wire sieve, as before, then smoothed by the tin. In watering I would recommend you to use only boiled water, for if you use such water as we are supplied with in Edinburgh, or even run water from roofs, you will find that if your seeds be long before they grow the pots will be covered with *Liverwort* before six months are run, which the growth of small seeds, or even pretty large ones, cannot penetrate. For my own part most seeds come better away under a higher temperature than that in which they subsequently grow, but once sprung, remove temperate things to more temperate quarters, and in genial summer weather an open frame, exposed to the rains and dews of heaven, is the best place for them; indeed, I have had hopeless things housed and so exposed for summer after summer. Some of the things above noticed, which took years to vegetate, were so exposed. There is yet a class of plants I have frequently had no little trouble and sometimes total failure to raise from seeds, namely, hybrids among various tribes. Among these I have had large experience, and over many years, especially in the case of

RHODODENDRONS, *Gentians*, *Campanulas*, *Silenes*, *Aquilegias*, &c. Many years ago I was especially induced to cross *Rhododendrons* with

Indian *Azaleas*, at all times a difficult cross. However, when the grand species of *Rhododendron*, *R. Aucklandi*, became known, I attempted and did succeed in crossing an Indian *Azalea* with its pollen, and though I allowed ample time, as I believed, to ripen, I found, to my disgust, when I had pulled the seed capsules, the seeds, though plump, were still green; yet hopeful, after drying them, that some would come, not one seed ever did. This taught experience, and experience hope, and I ever after gave all hybrid things more than the usual time for ripening normal seeds. But we must not stop here, but liberally extend the time for hybrid seeds when fully ripe for coming up. I found this especially necessary among the *Campanulaceæ*, which, among crosses of the smaller forms, such as *Waldsteini*, *pulla*, and the like, would take very frequently two years and more.

PLANTS IN FLOWER.

CYTISUS DECUMBENS.—This very small alpine species comes to us in flower from the York Nurseries. It is an interesting plant, but possesses no charm of form or colour which would make it valuable for gardeners. The colour is a poor lemon-yellow, and yet it may have a certain beauty trailing over rocks. It is a native of North Italy.

A WHITE-FLOWERED CEREUS has been sent to us by Messrs. Dicksons & Co., from their Filrig Park Nurseries, Edinburgh, and is said to be a seedling. It has very large flowers, with numerous narrow creamy white petals, and very handsome. It much resembles *Phyllocactus crenatus*, and indeed may be a seedling form of that species.

SOLANUM CRISPUM.—Some flowering sprays of this beautiful old half-hardy Chilean plant have been sent to us by Mr. Fuller, Meadfoot Lodge, Torquay, who states that they were gathered from a fine specimen some 20 feet in height, now full of blossom. The flowers, which are produced in dense clusters, are purple, with a yellow tuft of stamens in the centre. Their perfume is similar to that of Violet blossoms. This *Solanum* is an admirable plant for wall culture in the warmer parts of the country, and is even worth a place in a greenhouse.

PINK NAPOLEON III. is one of the best mule varieties that has yet been raised. It is hardy and an abundant flowerer, the colour, a glowing rich crimson, being very effective when seen *en masse*, as in the Filrig Park Nursery, Edinburgh, from which we have received some excellent flowers of it, as well as of another of a pleasing pale pink colour, also said to be a hardy free growing sort.

ELEOCARPUS DENTATUS.—A flowering twig of this pretty greenhouse shrub, sent to us by Mr. Bedford, the gardener at Straffan, shows how finely it grows under glass in Kildare; we have never seen such densely flowered specimens. The small, white, bell-like flowers, exquisitely fringed at the rims, are very elegant, and they hang in graceful profusion in axillary racemes about 3 inches in length. The leaves are of leathery texture, lance shaped, and obscurely toothed at the edges. We shall shortly give a plate of this shrub in THE GARDEN.

THE WHITE RAMANAS ROSE of Japan is again in bloom, flowers of it having been sent to us from Edinburgh by Messrs. Dicksons & Co., who grow it successfully in the open air in their Filrig Park Nursery. The pure white cup-like blossoms, with their tufts of yellow stamens in the centre, together with the handsome wrinkled foliage, combine to make it a charming garden plant. This white form of *Rosa rugosa* seems far less common than the typical purplish pink flowered sort.

ORIENTAL POPPIES.—Among some flowers sent by Mr. Green from Sir George Macleay's garden at Pendell Court, Bletchingley, are some distinct varieties of *Papaver orientale*, which are used with fine effect in the pleasure grounds there. In one part there is now a group some 10 yards square, and as the plants are all in bloom, the effect of

such a brilliant mass of colour may be better imagined than described. A variety with enormous flowers sent by Mr. Green as *P. involucratum* maximum is apparently synonymous with that known at Kew as *P. orientale majus*. The variety bracteatum may be distinguished at a glance by the cherry-red, not orange-scarlet, colour of the blossoms. Mr. Green also sends a double or rather semi-double variety of *P. orientale*, which is quite new to us. It is a highly effective sort, as the flowers are more massive and do not fall to pieces so soon as those of the type.

THE DOUBLE WHITE SCOTCH ROCKET, when well grown, is truly a handsome hardy plant. Finely developed specimens bear tall branching stems densely furnished with pure white rosetted blossoms emitting a strong perfume. Examples of this Rocket have been sent to us from the Pilrig Park Nurseries, Edinburgh, where it is evidently grown to perfection. Those who do not possess the true double white Scotch Rocket should by all means make its acquaintance.

THE ALPINE ROSES, as the dwarf European *Rhododendrons* are called, are pretty plants in large rock gardens just now. Their dwarf dense growth admirably fits them for planting amidst bold masses of rock, and all the better if placed so that they may fall over the ledges, thus showing off to good advantage their charming flowers. Messrs. Dicksons & Co. send us from their Edinburgh Nurseries some excellent specimens of the Myrtle-leaved kind (*R. myrtifolium*) and of *R. lancifolium*, both with clusters of deep rosy blossoms.

LILIAM SZOVITZIANUM.—One of the finest of all the early summer Lilies is now beautifully in flower about London, and we are reminded of its beauty by some fine specimens of it received from the New Plant and Bulb Company, Colchester, by whom Lilies have so long been made a speciality. This Lily differs from its near neighbour *L. colchicum* in having the inside of the turban-shaped blooms copiously spotted with black on a canary-yellow ground. Though so handsome in the garden, when cut these Lilies are unfit for indoor decoration on account of their strong and disagreeable odour.

PANSIES FROM HAWICK.—Scotch grown Pansies are proverbially finer than those of southern growth, a fact fully borne out by an extremely fine gathering of blooms from Mr. Forbes' nursery, at Hawick, in which the Pansy seems to flourish to perfection; never have we seen such beautiful Pansies in the south in the middle of June as those to which we now allude. Mr. Forbes seems to possess an endless number of named sorts, representing an infinite variety of colour. All are large and of what florists call fine form, some of the selfs and margined flowers being particularly noteworthy.

SAXIFRAGA PROPAGENA, though not a showy, is an interesting plant, on account of its peculiar mode of reproduction, which is by means of little buds borne on the slender branching stems seemingly in lieu of flowers. These buds are tiny rosettes of leaves, which, when detached from the plant, take root at their bases, and in this way the plant is propagated. The flowers, which are small, somewhat resemble those of the common London Pride (*Saxifraga umbrosa*). Messrs. Dicksons, of the Pilrig Park Nurseries, send us specimens of this interesting little plant.

THE ROSE ACACIA (*Robinia hispida*) is now the most beautiful of all hardy trees in flower; indeed, there is no other known to us which possesses such a combination of elegant growth and profusion of lovely blossoms; yet, for all that, it is seldom that we meet with good specimens of it in private gardens. It forms a low spreading tree with pendulous branches, at this season laden with long racemes of blossoms which hang gracefully from the undersides of the shoots. The flowers are about the size and shape of those of the garden Pea and are of a lovely rose-pink colour, which, in harmony with the fresh green foliage, has a pretty effect. It would be difficult to name a more valuable dwarf tree than this to

adorn a lawn or open shrubbery. It is perfectly hardy, but often being grafted on stocks of the common Locust Tree (*R. Pseudacacia*), it is liable to be damaged by high winds, the stem being frequently snapped asunder at the point of union. It forms at the present time quite a picture in Mr. Stevens' garden at Byfleet, and in the arboretum at Kew there are some very fine specimens of it, notably one on a rising knoll not far from the flagstaff.

TROPEOLUM POLYPHYLLUM is a plant particularly well suited for clothing a sunny bank of sandy, loamy soil, in which it thrives to perfection, and in such a position its long wreaths of golden blossoms intermingled with glaucous grey foliage are shown off to good advantage. It is now in full flower in London gardens, notably in the Hale Farm Nurseries, Tottenham, where it has taken up its position on an open bank and become thoroughly established, fearing neither heat nor cold, wet nor drought. Some long flower-stems of it are sent by the New Plant and Bulb Company, Colchester, which show well its usefulness when cut for vase decoration.

LONICERA SEMPERVIRENS MINOR, one of the North American Honeysuckles, is one of the prettiest twiners one can have in a cool greenhouse, and it is not only bright in colour, but almost a perpetual flowerer. For cutting, too, its slender twigs are invaluable, as each bears a cluster of bright orange-scarlet flowers, which have a pretty effect in vases. It is, moreover, an easy plant to manage, and is rarely so subject to insect pests as most other greenhouse climbers are. Some excellent sprays of it have been sent to us by Messrs. Dicksons & Co., Waterloo Place, Edinburgh, who state that it succeeds admirably in their nurseries under the protection of a cold pit.

THE OLD DOUBLE WHITE ROCKET when grown in such perfection as it is by Mr. John Gray, of Eglinton Castle, is indeed a most valuable hardy plant; a plentiful gathering of its flower-spikes testify to his skilful treatment of it, being much finer than any we have seen elsewhere this season. They are widely branched at their bases, and the main shoots are as massive and densely set with white rosette-like blossoms as those of a Hyacinth. Their perfume, too, is delicious, though perhaps rather too overpowering in a room. We sometimes hear that the true old double Rocket has nearly dropped out of cultivation, but it is evident that it still flourishes in northern gardens.

THE WHITE WEIGELA (*W. hortensis nivea*) is the most chastely beautiful of the host of varieties of Chinese Weigelas in gardens, and we are forcibly reminded of its beauty by a branch of it which has been brought to us by Mr. Joseph Stevens from his garden at Byfleet. It is nearly a yard in length, and the whole branch is profusely hung with snow-white blossoms, making a charming wreath. It is among the loveliest of all shrubs now in flower, but it is only to be met with in good collections. It is a robust grower, and soon makes a large specimen in good soil and with plenty of room to develop. It is distinct from any of the other varieties of Weigela, the leaves being of a paler green, broader, and more wrinkled. There is no chance of mistaking it even when out of flower.

VERBASCUM OLYMPICUM.—A gigantic candle-labrum-like spike of the Olympian Mullein, from Professor Foster's garden at Shelford, Cambridge, has been brought to us by Mr. Peter Barr. The length of the stem is 5½ feet, and from two-thirds of this length numerous branches are given off, varying in length from 1 foot to 1½ feet. These, like the main shoot, are densely covered with blossoms and buds, the former an inch or more across, and clear bright yellow. The large leaves which clothe the lower part of the stem are coated on their upper surfaces with a white, mealy substance as in *V. pulverulentum*. These tall-growing Mulleins well placed in a garden are noble objects in early summer, being not only bright in colour, but stately in growth—quite pyramids of bloom. Most of them are, however, unfortunately only of biennial duration, and require to be raised yearly

from seed in order to keep up a stock of flowering specimens.

LITHOSPERMUM PETRÆUM is a neat little bush, having narrow hoary foliage and small clusters of deep blue blossoms, with just a faint tinge of reddish purple upon them. It is a pretty plant for the rock garden, and we have never seen a finer example of it than that in the new rock garden at Kew, where it is grown admirably in an exposed position.

A WHITE PANSY OR VIOLA from Mr. Gray, of Eglinton Castle, Scotland, is one of the prettiest flowers we have turned out of a box for some time. Its soft white blossoms are so delicate in tone, and the form of the flower so elegant, that we are inclined to think it the finest light Pansy we have ever seen. It measures over 2 inches across the flower, and though the outline will not fit in the florist's circle, its form is what an artist would call good. Of its effect in the open air in beds or groups we cannot speak, but as a cut flower it is indeed a gain, a simple delf basket of it alone excellent.

BOMAREA CALDASIANA.—This beautiful greenhouse plant—best compared with a climbing *Alstroemeria*—is one of the most noteworthy plants in flower at Kew. A large plant of it covering a large space of one of the ends of the Cactus house—the coolest end—is carrying several of its large dense drooping clusters of orange and red spotted flowers, which are highly attractive. Planted out in a bed of good soil, these greenhouse *Bomarea*s are of easy culture, and *Caldasiana* never fails to yield a good crop of bloom every summer. It was figured in THE GARDEN, Vol. XX., p. 138.

ROBINIA PSEUDACACIA DECAISNEANA is the prettiest variety of the the False Acacia, or Locust Tree, we have in gardens. Instead of being white, as in the type, the dense drooping clusters of flowers are of a pleasing rosy pink colour. At Kew there is a finely grown specimen of it near the No. 1 Museum, and viewed against a background of dense foliage, its prettily tinted racemes, which hang in profusion from top to bottom of the tree, have an extremely pretty effect. Some excellent flowering branches of it, too, have been brought to us by Mr. Stevens in company with some other forms of the False Acacia.

A NEW ARROWHEAD from Chili named *Sagittaria montevidensis* may now be seen in flower in the Water Lily house (opposite the Palm house) at Kew. Its growth resembles that of our native species, and the leaves are of the same characteristic Arrowhead shape, but larger. The flower-spikes, which are erect, overtop the foliage, and bear whorls of large cup-shaped flowers, the petals of which are creamy white with a blotch of purple at the base of each, and edged with a ring of rich yellow. It is a pretty aquatic plant, and possibly may be hardy. It was, we understand, sent by Mr. Ball from Chili.

HYBRID VIOLAS.—From Dr. Stuart, Hillside Cottage, Chirnside, we have received some uncommonly pretty hybrid *Violas* of the cornuta race. There are four varieties, all of which are distinct and beautiful, and all have flowers about the size of small Pansies. Their names are Cream of the Valley, sulphur-yellow with an orange centre; Eyebright, the prettiest of all, the colour being rich velvety purple with a creamy white centre; Marmorata, prettily mottled and flaked with white on a violet-purple ground. There is also another of a soft white, with an orange centre pencilled with black in ray-like streaks. The Almond-like perfume of these *Violas* is not their least desirable quality. Though we have no means at hand of comparing Dr. Stuart's productions with older sorts, we are satisfied that he possesses some really beautiful seedlings.

Dear Strawberries.—In Covent Garden last week (June 14) was witnessed what is seldom seen in this country—a sale of Strawberries from the open air at 12s. a pound! We believe there has been no other example of open-air fruit selling at so high a price.

GOURDS AND THEIR CULTURE.

THE first record we have of any of the Gourd tribe being grown in this country occurs in 1370, when the coarsest form of the Pompion or Pump-

sent it would appear as if there was no country in which they are so little valued as they are in this. In America, France, and in fact all over the Continent, they are extensively cultivated as articles

ing collection of grafted Gourds in which fruits of diverse colours and forms were grown on the same plant. At one time scooped-out Gourds were used in the East as jugs and pitchers, and also as vessels

Patagonian Squash.

Bonneuil large white Cucumber.

Honfleur Melon.

Valpara's Gourd.

kin was introduced from the Levant. In Gerard's "Herbal" (1636) it is stated, "There be divers sorts of Gourds, some wild, others tame for the garden; some bearing fruit like unto a bottle, others longer and bigger at the end, keeping no certain fashion." This is still their character, and the interest which was taken in the family so long ago might well be renewed now; but at the pre-

of food and objects of interest. Annually, in autumn, there is an ancient and imposing ceremony in the Paris vegetable markets, when all the largest Pumpkins obtainable compete for the honour of being chosen king, and the biggest is decorated with a paper crown and carried round the markets. Some years ago M. Gaillard exhibited before the Central Horticultural Society of France an interest-

for holding wine. In his natural history of Barbadoes, the Rev. Mr. Griffith states that some of the Pumpkins grown there were large enough to contain 22 gallons of liquor. In English gardens some of the largest have weighed 200 pounds. Many more interesting facts might be recorded in connection with these plants, but probably a few practical notes bearing on their culture will be

more acceptable to your readers. The varieties of Gourds are very numerous, and may be included under three headings, viz., the Pumpkin (*Cucurbita Pepo*), the Squash (*C. Meloepo*), and the Vegetable Marrow (*C. succada*). The Vegetable Marrow was introduced into this country from Persia about the year 1700, and is the best known and most extensively grown of the whole family. As in the case of many other subjects, the original type has been greatly improved by hybridisers, and there are now some very choice sorts obtainable. The Squash finds more favour in America than in this country. A general collection of the whole should be grown by all who can find accommodation for them. Both ornamental and useful varieties should be included, and those here named and illustrated are types of the most valuable.

All seedsmen do not keep a full collection of Gourds, some only giving prominence to such as the Hundredweight, but others offer selected varieties, and it is these we would advise beginners to purchase and grow. Packets of seed, containing a mixture of many kinds, are generally cheap, and some curiosities may result from them, but mixed packets are never so satisfactory as small packets of distinct sorts.

PROPAGATION.—The plants are raised from seed. This may be sown at any time from February until May. Sometimes we have sown single seeds in small pots, and in other instances six or eight seeds have been put into a 6-inch pot. The first plan is the best, as the plants can then be potted on and shifted forward without disturbing the roots. The soil most suitable for sowing the seed in consists of loam and leaf-mould mixed in equal parts, with a little sand added. A few leaves put at the bottom of the pots answer as well as crocks for drainage at first. All the pots should be filled up, and then a small hole may be made in the centre of each with the forefinger, and into this drop the seed and cover up moderately firm. The pots should then be placed in a frame or pit where the temperature is about 60° or 65°, and here the young plants will speedily appear. When they first come up, the stems and roots are very tender, and a superabundance of water or a cold draught will often cause them to perish, and until the first rough leaves have been well formed, these injurious conditions must be avoided. A gentle bottom-heat makes the seeds germinate sooner, especially early in the season, but good plants may be raised without the aid of this. In the seed pot they should be grown as dwarf and stubby as possible, and in order that this condition may be secured they should be kept very near the glass, and on all favourable opportunities fresh air should be admitted. Although it is generally advisable to raise the seedlings in a house or Cucumber pit if they are wanted early in the season, yet, during April and May, a frame is one of the most suitable places in which young plants can be prepared for turning out in the open air. As soon as a few rough leaves have been formed, and the small pots are filled with roots, the plants should be transferred to larger pots. As a rule, 6-inch pots are large enough to grow them in until they are planted out. The pots should be well drained, and decayed manure may take the place of the leaf-soil. By the time the plants are large enough to be attended to in this way the stems will be of some length, and each of them should have the support of a stake. They are rather brittle, and if allowed to bend over may be broken off or severely checked in growth.

POSITIONS.—Gourds are sun-loving subjects, and luxuriate in warm spots. Cold, damp soils are unsuitable for their roots, and shade and cold windy draughts check the development of leaves and fruit; but there are situations in most gardens in which they may be grown to the highest state of perfection. Their squatty or scandent habits adapt them for adorning ugly mounds, or draping bare trellises, arbours, verandahs, or any place which it is desired to embellish with luxuriant leaves and diversified forms of grotesque fruits. The more varieties which can be grown the better, as

they differ so much from each other, especially in the shape of the fruits, and a good collection of them possesses a large amount of interest. It is too frequently the case that Gourds, like Vegetable Marrows, are grown in odd corners or on the tops of manure heaps, where their attractions are hidden and their crops lost. It is often necessary to conceal places of this kind, but this might be done with something less ornamental than the Gourd, and if a few of those who have opportunities of growing them would only give them a place in their dressed grounds and let them be seen in connection with the choicest forms of vegetation, the value of Gourds as decorative subjects would soon be generally recognised. Pleasure-grounds and not kitchen gardens are the right places for them. In planting them anywhere stiff soils and wet spots must be avoided. Where the soil is not naturally light and rich stations should be prepared for them, and in doing this we would always put a barrow-load or two of rough stones at the bottom of the mounds on which they are to be grown, as this insures the roots being kept in a sweet, healthy state. Each plant should have at least two barrow-loads of soil to grow in, and this should consist of three parts light loam and one of half-decayed manure. The smaller fruited varieties might have less soil than this, but where space will admit of it, they need not be too much restricted, as their greatest attractions only develop themselves under liberal treatment. When they are turned out of the pots to be planted, the balls of soil and roots which are attached to each should not be disturbed, and after planting they should be thoroughly watered. As soon as they begin to grow they must be looked at frequently to tie the shoots to some kind of support, and when the fruits form, should the larger-sized ones be those of the climbing kinds, the fruit must be tied in nets or have something put under them to prevent them from falling off. During warm weather large quantities of water must be given them, and any plants bearing very heavy crops of fruit will be benefited by liquid manure. Where the main object is to secure big fruits, a large mound of rich soil may be given them, and plenty of liquid is necessary to mature those monstrous fruits which we sometimes see in seedsmen's windows. Some of those we have known to attain a weight of 200 lbs, but while such are astonishing, they are not so interesting as the smaller varied and richly coloured fruits. Occasionally the fruits of some varieties are shy in forming, and when this is observed they can generally be fixed by fertilising the female flowers with the male blossoms. Besides being ornamental in leaf and fruit, many of the Gourds are valuable and delicious vegetables, but their uses in this way appear to be but little understood. According to many authorities in bygone days, they must have been looked on as a staple article of food, and they might still be utilised in this way. If used when young and tender they are equally good as any Vegetable Marrow, and all of them may be cooked in the same way. When the fruits are allowed to ripen, they may be gathered before frost has injured them, and preserved for use throughout the winter. We have frequently kept them in the fruit room throughout the winter, but when they are kept until the new crop comes in they require to be stored in a dry place, suspended in a net. In some seasons, when fruit for preserving has been scarce, Vegetable Marrows have been recommended as a substitute for making jam, and Gourds may also be used for this purpose, especially the Sicilian or Citron variety.—J. MUIR, *Margam, Taibach.*

The following descriptive account and illustrations are taken from *Les Plantes Potagères*:—

WAX GOURD (*Benincasa cerifera*).—Native of India and China. Annual.—A creeping plant which spreads over the ground like a Cucumber plant, with slender sharply 5-angled stems from 4½ feet to 6 feet in length; leaves large, slightly hairy, rounded heart-shaped, and sometimes with three or five faintly marked lobes. Flowers, axillary, yellow, with five divisions, which reach almost to

the base of the corolla, broadly cup-shaped, 2 inches or more in diameter. Calyx reflexed, pretty large, often petaloid. Fruit oblong, cylindrical, very hairy up to about the time of ripening, when it attains the length of from 14 inches to 16 inches, with a diameter of 4 inches or 5 inches. It is then covered with a kind of whitish flower or bloom, like that which occurs on Plums, but much whiter and more abundant, and constituting a true vegetable wax. Seeds, flat, grayish, truncated, numbering about 21 to the gramme (15 grains), and 300 to the litre (about 1½ pints). Its germinating power lasts for ten years.

Culture.—Similar to that employed in the case of other Gourds.

Uses.—The fruit is used like other Gourds. The flesh of it is extremely light, slightly floury, and intermediate between that of the Gourd and the Cucumber. It will keep pretty far into the winter.

VALPARAISO GOURD.—A plant with trailing stems 15 feet to 18 feet long. Leaves entire, slightly elongated, toothed, spiny on the edges, of a clear green colour, sometimes greyish, white on the upper surface. Fruit oblong, narrower at the two ends, from 16 inches to 20 inches long, with a diameter of 12 inches to 14 inches in its thickest part, somewhat lemon-shaped, ribs absent or hardly indicated, skin of a slightly greyish white, furrowed when ripe with a very large number of small cracks like fine tracery. Flesh yellowish orange, sweet and tender. A plant, unless it is an exceptionally strong one, should not be allowed to carry more than two fruit, as these often weigh from twenty-seven pounds to thirty-four pounds each, and even more. The fruit does not keep well.

CANADA CROOK-NECK GOURD.—This pretty little Gourd is closely allied to the early Carpet-bag Gourd, but differs from it chiefly in having the portion of the fruit which is next the stalk completely filled with flesh, as in the Naples Carpet-bag, and usually curved like the neck of a swan, in which respect it resembles the Siphon Gourd. It possesses the good qualities of earliness and excellent flavour, and also keeps well. The plant is of small size, the stems seldom exceeding 5 feet or 6 feet in length; it is therefore well adapted for gardens of moderate extent.

PATAGONIAN SQUASH.—A plant with very long running stems, and large, lobed, deep green leaves. Fruit from 12 inches to 20 inches long, and from 6 inches to 8 inches across, traversed from end to end by five very regular ribs, which form a kind of prominent rounded fluting; skin smooth, of an extremely dark green, almost black, a colour which it retains after ripening. Flesh yellow, of medium quality. This variety is remarkable for its hardness and productiveness.

EARLY BUSH OR SUMMER CROOK-NECK GOURD.—This plant is not a climber or trailer, but forms a tuft like the Elector's Cap Gourd. Leaves of a clear green, large, toothed at the edges, and more or less divided into three or five rather pointed lobes. Fruit of a very bright orange colour, elongated, covered with numerous rounded excrescences, narrowed, and most usually curved in the part next the stalk, and swollen at the other extremity, which, however, always terminates in a point. This variety is not a good one for table use; it is chiefly grown for ornament, like the fancy Gourds. From the hardness of its skin, the fruit is easily kept through the whole winter, and never loses the fine orange colour which distinguishes it.

BONNEUIL LARGE WHITE CUCUMBER.—This Cucumber, which is almost always grown in the open air, is quite distinct from all other varieties. The fruit, instead of being almost regularly cylindrical, is ovoid in shape, swollen about the middle, and, moreover, very perceptibly flattened from end to end in three or four places, producing the same number of angles more or less rounded. It is very large, readily attaining the weight of 4½ pounds. Like the fruit of the Early White Cucumber, it is at first of a pale green colour, and whitens gradually as it increases in size. This

is the Cucumber which is most generally grown about Paris for the perfumers, who use large quantities of it in their manufactures.

SMALL RUSSIAN CUCUMBER.—A truly miniature Cucumber, with a slender stem from 20 inches to 24 inches long, and small bright green leaves. It is readily grown in a frame, each plant producing from six to eight fruit, which are short, ovoid,

Small Russian Cucumber.

yellow, smooth, and a little larger than a hen's egg. This kind, which is the earliest of all, ripens fully in less than three months, and does not require any stopping. The flesh of the fruit has little density and is slightly bitter, but its remarkable earliness makes some amends for these trifling defects. In Russia there are many varieties of it, the earliest of which, generally producing but one fruit to each plant, is said to complete its entire growth in ten or eleven weeks.

GREEN-FLESHED SUGAR MELON.—A vigorous plant, with long branching stems, and very large, flat leaves, which are hardly ever toothed. Fruit oblong, contracted at the two ends, of a pale green colour, finely netted when ripe, and also bearing a number of excrescences of a pointed shape, ribs well marked, but not very prominent. Flesh pale green, extremely melting and sweet. The length of the fruit varies from about 8 inches to 10 inches, with a diameter of 4 inches to 6 inches. It usually weighs from about $4\frac{1}{2}$ lbs. to nearly 7 lbs. Two or even three fruit may be grown on each plant. This is especially a summer Melon, and only attains its full quality in very warm weather. It should therefore be grown in such a manner that the fruit may ripen during the month of August or early in September.

FLAT CORSICAN GOURD.—A remarkably distinct variety, with rounded and very flat fruit, like that

Flat Corsican Gourd.

of the Yokohama Gourd, but quite smooth and without ribs. It is from 6 inches to 8 inches in diameter and 3 inches or 4 inches thick.

YELLOW DUTCH CUCUMBER.—A usually branching plant with very slender stems and clear green

leaves with well marked angles. Fruit slender, longer in shape and later in ripening than that of the Russian Cucumber, but, nevertheless, well adapted for forcing. The colour is at first a yellowish green, but changes to pale orange-yellow when the fruit is quite ripe. There are seldom more than two or three fruit to each plant.

LARGE NETTED HONFLEUR MELON.—A very vigorous plant, with very branching, long, and remarkably slender stems. Leaves large, undulated at the margin, of a very light green colour, usually distinctly lobed, toothed on the entire circumference, and particularly so towards the extremity. The flowering is very continuous, and is prolonged on the branches even until after the fruit which were first set have reached their full size. Fruit very large, elongated, with well-marked ribs, and finely netted over the entire surface, taking when ripe a yellowish colour with a slight salmon tinge. It is often 14 inches to 16 inches long, and 8 inches to 10 inches across. When well grown the quality is excellent; it is latish in ripening. This and the Black Portugal Cantaloupe are the largest of all cultivated Melons. The variety is equally remarkable for its very great hardness.

BOTTLE GOURD.—Fruit contracted towards the middle, and presenting two unequal divisions, of which the lower one is larger and broader than the other, and often flattened at the base so as to allow the fruit to rest firmly upon it; the upper di-

Bottle Gourd.

vision, next the stalk, is almost spherical. There are some varieties of this Gourd, all of which bear fruit of nearly the same shape, but of extremely variable dimensions, some of them being nearly 20 inches long, and capable of containing at least 2 gallons, while others are hardly more than 5 inches or 6 inches in length, with a capacity of less than a pint, and they are found of all sizes between these extremes.

YOKOHAMA GOURD.—A Japanese variety of *Cucurbita moschata*, of very rampant habit, and somewhat late in ripening. Fruit flattened in shape, especially at the portion surrounding the eye, generally twice as broad as long, sometimes even more so; of a very dark green, with irregularly formed ribs, and the surface indented and wrinkled like that of the Prescott Cantaloupe Melon. It is identical with the *Cucurbita meloniformis* of M. Carrière, described in the *Revue Horticole* for April 1, 1880, and November 16, 1880.

In addition to the above, the following varieties of Gourds include some of the best in cultivation: Grand Mogul, Sicilian, Pasha of Egypt, Elector's Cap, Giant's Punch-bowl, Cork Oak-skinned, Mammoth, Bishop's Hat, Marble Head, Cricket-ball, Turban, Bordeaux Melon, Plover's Egg, Pear, and Bottle.

Lawn mowers.—I will have no more to do with Mr. W. J. May's challenge until he unreservedly accepts the conditions offered by me in THE GARDEN of May 12, which he now virtually declines to do, and breaks his own original conditions further by reducing the distance from Lon-

don from 250 miles to 20 miles. I leave it to your readers to judge who it is who is "afraid of results." Mr. May first declines my reasonable stipulations and next narrows the range of his challenge down to a fraction of its original compass. I see he states in the *Bazaar* that a little girl of eight years used a 14-in. machine, and cut grass with it that was both "long and wet and uphill!" —AN OLD LAWN MOWER.

NOTES FROM THE SOUTHERN ALPS.

(Continued from p. 536.)

AMONG the crags which lay piled one on another above this path grows

THE WARATAH, a plant of which I have heard for years as the chiefest glory of New South Wales and Tasmanian flowers. And there at last was the Waratah (put the accent on the first syllable), and I think on the whole I was disappointed. I must say, however, that the bushes I met with had not many flowers. A bush with a large number of flowers must be a very magnificent sight. On my second ascent of the mountain I should have made my way to the headquarters of this shrub, but unfortunately a steady downpour of rain set in, and I was obliged to fill my vasculum as quickly as possible and descend. Once a year the Hobart people grow Waratah mad—men, women, and children, natives and visitors are all touched with the Waratah disease. The very larrikins (this is the colonial term for the Mohocks of the spectator) make up parties to go to the mountain on a Saturday evening, where they encamp all night, sallying forth at daylight on Sunday to gather the Waratah blossoms. The first question asked of the people at the Springs is "Where does the Waratah grow?" and when you return from your first ascent of the mountain, whoever meets you—the landlord, or his wife, or his daughter, or his man-servant, or his maid-servant, or the stranger that is within his gates—the question still is, "And have you seen the Waratah?" This Waratah is the *Teloepa truncata*, the "flower seen from afar," a woody shrub ranging from 6 feet to 10 feet high, bearing corymbs of crimson flowers at the points of the twigs after the manner of a *Rhododendron*. Imagine a corymb of rich crimson Honeysuckle set in a ring of small leathery leaves, and you will have a tolerable idea of what this flower is like. The heads of bloom vary from 2 inches to 3 inches across. They consist of single florets, each set on a long peduncle, the petals curling outwards and concealing the stamens, the pistil arched above the petals like an index finger, and in each floret, like a brilliant, glistens a drop of honey. But there is yet another feature of the Waratah which probably goes far to make it such a favourite. It may be kept in water for days; indeed, if you cut an undeveloped flower, for weeks. Some of the less expanded flowers which I found I kept in a glass in my hotel during my whole stay in Hobart, and had considerable pleasure in watching them unfold new beauties every day. I do not know any summer flower of the same staying powers. It is, however, a difficult subject to grow. Six small plants which I brought from Mount Wellington are looking worse than doubtful. Although I was fortunate enough to find one or two Waratah plants in flower, the place where it abounds lies about three miles in the opposite direction—almost under the "Organ Pipes." Another noteworthy plant which I met with in my aberration from the proper mountain path, and which I thought a more beautiful object than even the Waratah, was

THE GRASS PLANT (*Richea dracophylla*). The Grass plant is singular as well as beautiful. The bare woody stem rises to a height of perhaps 10 feet or 12 feet, and at this height there springs out a crown of flexuous Grass-like leaves of a light glossy green, bearing a panicle of flowers sometimes as much as a foot in length. The colour is a good substantial white, and the whole bloom has much the appearance of an elongated white *Tritoma*. Along this part of the mountain the wreaths of *Clematis* were very rich. On the lower ground, the pastures around Hobart, this

Clematis assumes a very curious form, so different from the normal, that it has appeared to many to be a true species, and has received the name of *Clematis gentianoides*. It has quite lost its climbing propensities, and is dwarf in habit, ranging from 6 inches to 18 inches in height. It bears a solitary white flower, and growing in the meadows has much the appearance of a white Anemone. For anyone who finds only the extreme forms of this plant it is difficult to believe that they are not well defined species. But Baron von Mueller, who has had better opportunities of observing this genus in Australia than any other botanist, tells me that he believes it to be only a form of *aristata*. After having gone about two miles and finding that I made little, if any, ascent, I concluded it would be better to retrace my steps and make anew for the top from the Springs. At this return point the mountain makes a sublime picture of desolation. Away towards the crest the further side, bounded by

A FOREST OF BLASTED EUCALYPTI, rolls a sea of boulders, swept bare even of Lichens by the wind which rushes over them from the southern ocean. Strewn over this dreadful surface, like the colossal spars of a wrecked armada, lie thousands of dead and dying Gums bleached by the weather to the lifeless grey of the rocks themselves. Here and there a whitened trunk lies stretching "many a rood" from rock to rock, whilst in other places chaotic masses of shattered branches, black with the mark of fire, lie huddled in grotesque confusion. And look at your foot; such is the grim irony of Nature, you find growing in a crevice of those merciless boulders the fairest, frailest of ground Orchids, *Caladenia carnea*—so fragile that it shrivels at a touch; "slight, to be crushed with a tap of your finger nail"—graceful and exquisitely coloured like a shell, and a step further, behind the rough stone shelter, is the quaint, delicately veined *Pterostylis*, hooded like a Capuchin of the olden time. The proper path to the mountain top lies behind the Springs hut. Several interesting plants grow along this path. Amongst the stones which pave the path itself creeps *Rubus Gunnianus*, most diminutive of the Bramble family, growing not more than an inch high, and bearing little yellow flowers nestling amongst the leaves. The fruit is large in proportion to the plant, and is said to have an excellent flavour, somewhat like that of the Cranberry. Two *Veronicas* grow here. One with much divided leaves, *Veronica nivalis*, would make a good border plant, and ought to be hardy even in England. The other, with lilac flowers, a shrubby variety, I have not been able to identify. A large number of composite flowers grow on either hand, belonging chiefly to the genera *Aster* (*Eurybia*) and *Helichrysum*—genera of which the species are not always easy to distinguish. Mueller, in his "Census of Tasmanian Plants," enumerates seventeen *Asters* and twenty-four *Helichrysms*. The *Asters* and *Helichrysms* on Mount Wellington are mostly shrubs. One *Aster* (*stellatus*) forms a large ingredient of the underscrub, making whole slopes gleam with its white Daisy flowers. Some bear heads of silky white; others vary to sulphur-yellow and even pink. The species I collected were, of *Asters*, *viscosus*, *stellatus*, *florulentus*, and *Celmisia*; and of *Helichrysms*, *ledifolium*, *rosmarinifolium*, *antennarium*, *obcordatum*, and *baccaroides*. On this part of the mountain, too, grows the pretty silky *Pimelea sericea*. A short distance from the top, growing amongst the loose detritus of disintegrated rock, are whole beds of the prostrate shrub

BAUERA RUBROIDES, at this time bending with its long sprays of white blossom. Sometimes the blossom is flushed with pink, but these were of untinted white. This plant seemed to me the very perfection of an alpine shrub. Patches of seedlings grow all around in great abundance, and I must have sent home six or seven clumps, of which a very small fragment of one seems to be growing. Near the *Bauera*, but higher up, are sheets of the lustrous waxy white of *Epacris serpyllifolia*, one of the finest of *Epacrids*. It must be very hardy to stand the winter climate of Mount

Wellington. Sometimes it is an erect shrub, sometimes it follows the outline of the boulder against which it grows like a climbing plant. This style of growth is no doubt caused by the force of the wind at the top, and is characteristic of other shrubs, such as *Leptospermum scoparium*, which sometimes forms quite a network over the stones, the force of the wind really preventing it from lifting its head above the support. On emerging from the belt of stunted trees that fringe

THE BALD TOP OF THE MOUNTAIN, one comes out on what is called the "Ploughed Field." This is a large area of enormous boulders of all shapes, leaning one on the other at all angles, a field unbroken even by the stump of a fallen tree. Amongst geological phenomena this field is a thing of its kind, and the suggestion of the enormous power that must have hurled those fragments of an earlier world into their places gives them a wonderful impressiveness. Skirting a corner of the "Ploughed Field," you at length, by a series of steps consisting of large boulders, reach the table-land that crowns the top; and then you make your way for what seemed to me about two miles along this rocky plateau to the highest point, behind the "Organ Pipes." As I got out on the top, the south-west wind blew with a force and a cutting keenness, which made me, after my warm ascent, fain to crouch for shelter behind the rocks; but the distance before me, and still more the distance behind, and the erratic skirmishing of threatening clouds overhead advised a steady push forward. The route still ran between large boulders, lying singly or in groups and leaving spaces of level ground between, covered with their appropriate alpine vegetation. Specimens of the pretty *Bellendena montana* with its spatulate lobed leaves, of the *Hakea*-like *Orites revoluta*, of the dwarf and prickly crimson *Richea Gunni*, and of *Richea sprengeloides*, with compact balls of peat, soon found their way into my vasculum. Here and there in hollows between the rocks were small pools and bogs, in or around which grew such things as *Euphrasia collina*, covered at this time with white *Minulus*-like flowers, *Droseras*, and *Wahlenbergias*. Arrived at the very top, I did not fail to find an old friend who is invariably ready to welcome one to the tops of mountains on this side the world. Down in the holes between the boulders, a drop of 6 feet or so, in cosy nooks which must be warm and snug even when the snellest winds are whistling amongst the Organ Pipes, you are sure to find the ubiquitous little *Lomaria alpina*. Unfortunately time did not permit of my paying much attention to the Gums that grow on Mount Wellington, beyond remarking their size and general appearance. From the Springs upwards the glaucous cider Gum (*Eucalyptus Gunni*) is common, and the smallest of the whole genus, *Eucalyptus vernicosa*, is said to grow at the top. I am curious to know to what extent the plants I have described or enumerated are grown in England; perhaps some of the readers of THE GARDEN would be good enough to state their experience of some of them.

PAKEHA.

Transplanting Ampelopsis Veitchi.—It may interest some of your readers to know that old plants of this beautiful wall coverer may be easily transplanted. I have at times tried, and partially succeeded, in transferring Ivy in sheets from a wall to a position against another wall, but the *Ampelopsis* is more easily dealt with. By beginning at the bottom and pulling the branches away steadily the whole plant will come away without the loss of a twig, notwithstanding the very firm manner the shoots adhere to the bricks. I have during the past few years moved plants 12 feet high and 8 feet or 10 feet across. When planted the shoots are temporarily nailed to the wall till the young growth has made some progress and taken hold, when the nails are removed. The old wood never regains its hold of the wall, but the young growths are so plentiful that they are quite able to support the weight of the plant however large. This *Ampelopsis* does well in our cool climate. Plants put out of 3-inch pots about

eight years ago are now at the top of a wall 20 feet high or more, and clasping the parapet pillars above them and invading the roof beyond.—J. S.

ROSE GARDEN.

THE FIRST ROSES OF THE SEASON.

So far as I am aware, the first Roses on the boards this season were those shown at Lexden Park, near Colchester, Essex, on the 13th and 14th inst. The Colchester and East Essex Horticultural Society held their show in connection with that of the Essex Agricultural Society. The two have run abreast for some years. Both shows were highly creditable to the societies represented. But my business now is with the Roses. The first thing that strikes one in regard to these is their fewness in the middle of June, thus giving the strongest confirmation to what I have stated concerning the

ABNORMAL LATENESS OF THE SEASON. Though prizes of five, three, and two pounds were given for thirty-six Roses, only one stand was exhibited. Prizes of equal value, with the exception of £1 10s. for the third best twenty-fours, only succeeded in drawing one collection. Prizes of three guineas, two guineas, and one guinea for twelve only brought out three collections, and in the six Teas and six Roses there were but three of each. A dozen *Gloire de Dijon* and six *Maréchal Niel* made up the first Rose show of the season. The next point was the preponderance of Tea to other Roses. This was only to be expected. Teas are indeed invaluable for early work, especially if grown in warm nooks and corners, or on walls or fences. Some of these, too, such as *Marie Van Houtte*, *Niphetos*, *Rubens*, *Souvenir d'un Ami*, and *Devoniensis* were in very excellent form. Perhaps few Tea or other Roses can equal *Marie Van Houtte*, as seen at the Colchester show and elsewhere this season, so large and full, of perfect form, and the softest colour yellowish white blushing into a deeper shade in the centre of the flower, the outside of the petals slightly or deeply stained with bright rose colour. *Cheshunt Hybrid* was also in great force, and is rapidly establishing its character as one of the most useful and beautiful of all the early blooming Roses. Among

OTHER ROSES seldom seen so early, or indeed at any season on winning stands, were *Souvenir de la Malmaison*, *Bougère*, and *Belle de Bordeaux*. The first is a Rose of exceptionally fine form, without any hard or malformed centres this year, and the two second are seldom found on winning stands; *Bougère* is, however, still one of the best, most useful, and floriferous of all our pink Roses. The following lists will, it is hoped, have a general interest in indicating those Roses that are likely to bloom first, a matter of considerable importance to exhibitors and the general public. Mr. Benjamin Cant, of Colchester, had a capital thirty-six, quite strong enough to have held their own against a good many competitors. His Hybrid Perpetuals were *Abel Grand*, *Alfred K. Williams*, *Charles Lefebvre*, *Dr. Andry*, *Dupuy Jamain*, *Duke of Wellington*, *Exposition de Brie*, *John Hopper*, *Jules Margottin*, *Madame Lacharme*, *Maurice Bernardin*, *Miss Hassard*. *Bourbon*: *Souvenir de la Malmaison*. *Teas*: *Anna Olivier*, *Catherine Mérimet*, *Comtesse de Nadailac*, *Devoniensis*, *Etoile de Lyon*, *Gloire de Dijon*, *Goubault*, *Jules Finger*, *La Boule d'Or*, *Madame Angèle Jacquier*, *Madame Lambard*, *Madame Welch*, *Madame Willermoz*, *Marie Van Houtte*, *Moiret*, *Niphetos*, *Rubens*, *Souvenir de Madame Pernet*, *Souvenir d'Elise*, *Souvenir d'un Ami*. *Noisette Roses*: *Lamarque*, *Maréchal Niel*. *Hybrid*: *Cheshunt Hybrid*. Mr. Rushmore, the well-known successful rosarian of Tendring Hall, was first with twenty-fours and twelves with the following: *Twenty-fours*—*A. K. Williams*, *Gloire de Dijon*, *Duke of Edinburgh*, *Céline Forestier*, *Bougère*, *Dupuy Jamain*, *Comtesse of Rosebery* (this is a newish Rose of fine form and reddish colour with a dash of salmon in it that also promises to be among the ear-

liet), Madame Caillat (an oldish, large and full, salmon-rose-coloured Rose seldom seen at exhibitions), Princess Mary of Cambridge, John Hopper, Souvenir d'un Ami, Charles Lefebvre, Niphetos, Jules Margottin, La France, Cheshunt Hybrid, Maréchal Niel, La Boule d'Or, Miss Hassard, Abel Grand, Marguerite de St. Amand. Twelves: Adam, Perle de Lyon, Charles Lawson (it was quite refreshing to find this most useful old favourite in a winning stand), Rubens, General Jacqueminot, Maréchal Niel, A. K. Williams, Niphetos, Cheshunt Hybrid, Bougère, Catherine Mermet, and Mdme. Caroline Kuster. Among

THE WINNING STANDS of six Teas the following were the more conspicuous flowers in addition to those already named: Madame Bravy, Alba rosea, Reine d'Or, and Comtesse de Nadailac. Reports of Rose prospects were of the rosiest hue, and the general consensus of opinion seemed to be that what this Rose season had lost in regard to time it might yet more than regain in brilliancy. Can it be another and a last legacy of the frosts of March that the Roses are closer to the old wood than usual? Hardly had the shoots fairly started into growth till the brilliant sur-shine and long drought forced them into flower, leaving but short supplies of wood for the furnishing of buds, or the support of fine Roses in vases or other floral decorations. The late pruner, or those that deferred pruning till the end of March, have fared best this season. D. T. FISH.

THE ROSE BLOOM.

I AM glad that as a lover of Roses I do not live in East Anglia if Mr. D. T. Fish's experience at Hardwick is that of the whole district. It would be a sorry look-out for Rose lovers this year if things were in the woeful plight which he seems to think they are, but this is not an unusual style of prophecy with him, for I look back on past years and find that hardly ever were Rose seasons likely to be to his liking; he wrote to me some time ago, after that severe blast of weather in March, to say that all the wood is so injured as to be worthless. I went out into my garden and cut some pieces of both Teas and Hybrid Perpetuals and sent them to him. The wood was perfectly sound, although, of course, the young shoots, an inch or two in length, were killed, but the wood itself was untouched, and now, close as we are on the Rose season, with all its excitements, expectations, hopes, and fears, he still writes of the general weakness of Roses everywhere this year. Now, not only is such not the case, as far as my knowledge goes, but I have not for years seen so good a prospect of a fine Rose season as at present. I have had the privilege of visiting the gardens of some of our most successful growers in our southern counties. I have also had numerous letters from correspondents in various parts of the country, and the universal feeling is that, unless the unforeseen happens, we shall have such a season as will heartily rejoice all lovers of the Rose. We are now in June; the first Rose show will, I believe, be that at Cardiff on the 27th inst., and I may say, as an encouragement, that I have not in all the gardens I have visited, or in my own, as yet detected a single aphid. This is to me a most unusual circumstance, especially as we have had lately a good deal of easterly winds and hot sun, which are considered conditions generally favourable to their development. They may come yet, but they can be much more easily attacked now than earlier. The same absence of vermin, as the Hop growers call them, is observable in the Hop gardens, which look clean and bright. Then, again, there has been very little maggot. I was going through the garden of one of our most experienced Rose growers the other day, when he observed the same thing; in fact he said so little has there been, that I have hardly looked after them, and consequently in one or two cases they have taken advantage of this and so escaped detection. I notice on most things the same absence of insect pests; cuckoo spittle, as it is popularly called, is very scarce, so that these drawbacks to a good Rose season are removed.

There can be no greater mistake in the cultivation of Roses, if you want good flowers, than not to disbud. If you do not do so, and smaller buds surround the large central bud, you cannot cut it without them, or else cut it with so short a stalk as to deprive it of a good deal of its beauty; nor can you cut foliage with it, and whether for the exhibition table or the specimen glass this is undesirable. Moreover, if you give each shoot only one Rose to develop, you have the better chance of a second blooming time. When the one Rose is cut, the buds which are at the end have a better chance of shooting off afresh and giving you a later bloom. Like all operations of the kind, it requires some courage to do it, but you gain your reward by the greater excellence of the flowers and the greater vigour of the plants.

There is one point in Rose growing which I should like to be well noted this season, if Rose growers would kindly take the trouble, and that is the manner in which different stocks are suited to different Roses. I do not mean the general question as to whether the Manetti or Brier (be it seedling Brier or Brier cutting) is suited for Roses, but as to the different varieties. Let me instance as an example that grand Rose, A. K. Williams. I have myself a very strong opinion that the Manetti stock is not suited for it; my soil is not a Rose soil, it being too rich and light for Roses, and it is only by the addition of turfy loam that I can make it grow them at all. I have planted a small bed of A. K. Williams, half on Manetti and half on seedling Brier and Brier cuttings. They were from the same nursery and treated exactly in the same way. Of these, one half on the Manetti are dead and none on the Brier, while in looking through my other beds I find the same thing—those on the Manetti have disappeared, those on the seedling Brier flourish. This may account for the different opinions that have been expressed as to the constitution of the Rose, some contending that it is weakly, others that it is vigorous. It is clear that if those in my own garden are a fair sample of others, we might easily overrule both statements. There are other Roses which may be in a similar condition, and I think it would be a matter well worthy of study by those who have time at their disposal to make experiments in this direction. I hope that I may prove the truer prophet, and that we may look forward to a good Rose season. All will depend on the character of the weather of the next three weeks. DELTA.

Rose fixtures.—There is no doubt it would be a very desirable thing if these could be so arranged as not to clash. But what can be done? There is not more than three weeks in which they can take place, *i.e.*, when the Rose season is at its height. Now, as there are some twenty or thirty Rose shows to be held in that time, it is evident that they must clash sometimes, and all the plans Mr. Fish suggests would not hinder them doing so. Then, again, there are local circumstances which regulate the days on which exhibitions are held. More especially do market days influence them. It is in order to get as large a company as possible to have them on those days which are not movable feasts, and hence, for example, Farningham must be held on the same day as the great show at Bath, and Shrewsbury also claims the same day for the same reason. The Crystal Palace Company must have their show on a Saturday, and so must Brockham and Reigate. The best is done under these circumstances that can be done; and as the days of the exhibitions of the National Rose Society are fixed early in the year, all other societies do, as a rule, keep clear of them. The result of all is that Rose growers cannot exhibit at all shows, and have to make their choice.—DELTA

Rose leaf-eating grub (*R. Connell*).—The insect forwarded to me is a caterpillar belonging to the family commonly known as loopers, from the peculiar manner in which they hunch up their backs when moving about. This particular kind will eventually become a moth, belonging to the genus *Biston* one of the *Geometridæ*.—G. S. S.

FRUIT GARDEN.

STRAWBERRIES IN PITS AND FRAMES.

As the time is at hand when Strawberries should be prepared for planting, allow me to direct attention to a plan whereby ripe Strawberries may be obtained in advance of those from the open ground, simply by planting in pits and frames. The plan will be found useful by those who have not the convenience of growing Strawberries in pots, and placing them in a suitable structure to ripen their fruit. All that is wanted is a bed of good soil and a cold pit or frame to secure a fine crop of large fruit without the aid of fire heat or any other expensive appliances. The first step is to select a suitable variety for the purpose. My choice would be between Keen's Seedling and President, both of which are known to be excellent croppers and good in flavour, but as Keen's Seedling is a little the earliest, it may be desirable to select an equal number of each, when under the same treatment one would form a succession to the other. The number of plants required will, of course, depend upon the space to be devoted to them. A light 6 feet long and 4 feet wide will require eighteen plants, that is, three rows with six plants in each under one light. One has therefore only to decide how many lights will be occupied to find out the number of plants needed, but I may remark that less than two lights of the size just mentioned would furnish but a limited supply.

THE PREPARATION of the plants is not a difficult matter; for this purpose runners should be selected as early as they can be got. The best way to get them rooted quickly is to peg them down on the soil, first stirring up the surface with a trowel and breaking to pieces any hard lumps; then with a peg fix the runner down firmly. In order to obtain the best results it is essential that strong plants with plump crowns be secured early in autumn, and to enable one to get these the runners must receive attention in the way of watering, so as to induce them to form roots quickly. In hard ungenial ground it will help the runners wonderfully if a couple of handfuls of fine rich soil is placed on the surface for them to root into, which they will freely, and, what is equally important, they will lift better. In fact, any extra attention at this stage will increase the prospects of a crop in a way that no care as regards after management can possibly do. In three weeks the plants will be sufficiently rooted to bear removal. The next step is preparing a piece of ground for them, which should be an open, sunny spot, and made both rich and fine, and if a couple of barrowloads of road grit or coarse river sand can be strewn on the surface and lightly raked in, it will induce the plants to root better than they otherwise would do. When the ground is ready, cut the runners off close to the crown, and then the plants should be carefully lifted and conveyed on a hand-barrow to where they are to be planted. They should be put in 12 inches apart each way, and if the ground is dry a good watering should be given, and continued at intervals of every two or three days if the weather remains dry. A light shading for the first few days if the weather should be very bright would also be beneficial. This may consist of a few Evergreen branches stuck in between the plants, which, with the exception of keeping them free from weeds, will be no further trouble until it is required to take them to the pits in which they are to fruit. In these bottom heat is not a necessity; in fact, a strong bottom heat would be injurious, but a little warmth below the roots might stimulate them to make an earlier growth; further than that, however, it would be of no service. A brick pit is to be preferred, especially if ripe fruit is wanted as early as it can be had, as it affords greater warmth and shelter than a wooden frame; but, with the exception that there would be a slight difference in the time of ripening, one is as good as the other, whichever is used. A bed of good rich soil not less than 8 inches or 10 inches in depth is necessary for the reception of the plants, and the surface should not be more than 9 inches from the

glass. If the pit or frame should be a deep one, the space below the soil may be filled with any ordinary soil, or any refuse that comes to hand that is not likely to sink. If ripe fruit is wanted as early as it is possible to get it, the first plantation should be made about the middle of February, but if the planting is done on the 1st of March it will be soon enough for all ordinary purposes. As a matter of course, the plants must be lifted carefully in order to preserve all the roots possible. The soil must be pressed firmly about them and kept regularly moist by watering. For the first three weeks after planting very little air will suffice, but as the leaves advance in growth more air at the back of the pit must be given, and the lights should be protected every night with mats. When the fruit begins to form, a surface covering of Cocoa-nut fibre refuse will keep it clean and help to keep the soil moist. I am of opinion that if it were generally known what excellent crops of Strawberries may be thus obtained, many would prefer to grow them for late crops in the way just described instead of cultivating so many in pots. J. C. C.

VINES AND TOP-HEATING.

"A. D." (p. 507), in referring to this subject, complains that discussions invariably run off into side issues, and forthwith invites this by speaking of an imaginary "opposition of hot-water doctors" to Mr. Cannell's system, which is not used for Grape growing. As I do not think there is a vinery in the kingdom with a system of top-heating such as "A. D." implies is wanted, a discussion thereon can only be theoretical, or so far practical by comparison with houses used for other purposes.

Personally, and as a hot-water doctor, I believe in the arrangement as most beneficial and economical, and for many, many years have been trying to get gardeners and others to see the benefit and economy of it, but in vain. Over fifteen years ago several trellises for Vines were so arranged that the frames of small tubes could be filled with hot water and give a little warmth at intervals of 4 feet or 5 feet up the roof. Though the trellises were so fixed, the idea was considered too fanciful to be put to the actual test, and I do not believe the connections with hot-water mains were ever made.

The low houses where pipes are only 18 inches to 2 feet from the Vines are really plentiful, as the hundreds of Paxton roofs used for Vines, including the first one erected by the patentee, of which a photograph is before me, will testify. The reasons why the lower bunches of Grapes in cases named are the finest may be various (that is open to discussion), but in many instances I do not doubt that the lack of good bunches above is due to a want of warmth at critical times, which a small pipe half way up the roof would have supplied better than two or more large ones placed near the path or centre of the house, as is often done now-a-days. If the system adopted by Mr. Cannell is useful for houses devoted to low-growing plants, how much more should it be in vineries, where the plants are placed in the coldest part of the house, that is, near the glass. Even the training of Vines at 18 inches instead of 12 inches from glass is an advantage, because the night temperature will be more agreeable at that little extra distance.

I wonder that some of our great Grape growers have not tested their temperatures in different portions of the same roof, and placed their observations on record with their own deductions therefrom for others' guidance or discussion. A certain average temperature is spoken of as necessary, and now and then one reads of the opposite practices of certain growers in this respect, both being equally successful with a difference of 10° to 15° possibly. The real cause has been missed, I fancy, in each case. Take the common instance of a vinery with 16 feet rafter, 13 feet width and 13 feet height, length immaterial, with two 4-inch pipes near the front and two more at 5 feet from the back wall. A thermometer placed on the back wall or probably suspended at 4 feet above the border next the path, indicates a minimum of 50° or 55°, and though there

may have been some degrees of frost outside during the night, all is supposed to be well. However if three instruments had been placed at 6 inches below the glass, one near the bottom, another in the centre, and the third one at 3 feet from the top, I will undertake to say there would be found some such figures as 60° to 50° over the front pipes, and from 50° down to 35° in the other positions, or a variation of 15° in the length of Vine rod, owing to the frosty air penetrating the glass and laps. The two pipes near the path only serve to mislead the gardener, by keeping up a fictitious average temperature at the point where the thermometer is, and where the Vines are not. Abolish these two 4-inch pipes and place two small ones at one-third and two-thirds of the space between front pipes and top of the back wall, and I will guarantee that the atmosphere in which the Vines are actually growing will be more uniform from foot to top than is possible with any ordinary method of heating, even where six pipes are in use. Another method of obtaining a more equable temperature so desirable for good Grapes is to have a double roof with a space of 6 inches between the glasses, at the bottom of which space one hot-water pipe should be placed. In this way better results will be obtained with 4 pipes than is now got from 6 pipes, thus saving first cost of pipes and much fuel, which saving would soon cover the cost of extra glass. Neither would there be such a rapid rise of temperature with sudden sunshine, and much anxiety as to the admission of cold air or ventilation on this account would be saved. By the arrangement of small upper tubes, either as part of the wire framework or separately, the dampness (so much dreaded) could often be driven out, and a movement of air secured without actually heating the house below. I trust I have stuck to the point, and that some more practical men will take the matter up.

B. W. WARHURST.

5004.—**Air roots on Vines.**—So far as my observations have extended, these are in no way injurious; at the same time I would rather not see them; and it is this studying of appearances that has led me to make repeated trials to prevent their growth, but hitherto without avail. Like most other practitioners, I believe that their formation and extension arise from inequality of temperature between root and branch, a theory that to some extent is confirmed by the fact that their growth is much more general in early vineries than in others, and this being the case, the way of prevention is obvious, viz., more warmth to the roots and less moisture, and more air internally. But from my point of view, the application of such remedies would be worse than the disease, that is, if it can be called a disease—certainly, it is a very harmless one, so that personally I am content to let the Vines have their own way in this matter.—W. W. H.

Summer pruning Currant bushes.

After trying the summer pruning of Currant bushes for several seasons, I can recommend it as labour well spent; not only is the crop of the current year improved by the removal of what would become a mass of superfluous growth, but the buds that are to produce next year's crop are strengthened by the exposure to light and air to which they are thus subjected, and above all by the leaves at the base of the shoots being retained fresh and green until the end of the season, instead of becoming blanched and dropping off early, as is the case when all the shoots are allowed to grow unchecked, thereby forming a dense shade. The best time to remove the points of all the erect growing shoots is while they are soft and green, i.e., about the middle or end of May. They can then be readily nipped off. If any want to test the merits of this practice, let them pinch half their bushes of Red and White Currants (Black sorts must not be so treated), and leave the other half to grow at will; they will then soon be convinced of the benefits arising from summer pinching. On walls devoted to Currants this

practice is especially necessary, and the fruit being thoroughly ripened by the timely removal of the points of the shoots will prove invaluable for late dessert purposes. It is worse than useless to leave the shoots intact until the fruit is ripening and then remove them, as the leaves at the base of the shoots will then be either wholly or partly inert by being long shaded.—JAMES GROOM, Gosport.

GARDEN FLORA.

PLATE CCCXCIII.

THE CHRYSANTHEMUM.

(THREE NEW VARIETIES.)

WHEN all outside blossoms have faded or are cut down by frost, when the time of Roses is past and the fogs of November embrace us against our will, then a gleam of floral sunshine comes from the Celestial empire, and we welcome it under the homely name of Gold Flower, or Chrysanthemum. The Chrysanthemum is, or may be, everybody's flower, since all may grow it in windows, in gardens, or by sunny walls, but it is as a winter-blooming conservatory plant and as a florist's flower that we now more especially wish to speak of it. If you wish to see the Chrysanthemum of the "fancy" you may find it portrayed by the late Mr. Andrews in the pages of the *Florist*, or in the *Floral Magazine* in the form of a cricket ball, perhaps larger, and with its rounded florets arranged as symmetrically as slates on a roof. This regularity seems to me the keystone of the florist's faith—this one word, "symmetry," and the harm it has wrought in our gardens, is far more than I or anyone else can ever hope to tell. And so the Chrysanthemum of the florist was ever symmetrical, as were his Tulips and Dahlias, and all other of Nature's flowers with which he dealt. It is nearly half a century since seedling Chrysanthemums were first raised in English gardens, and I am not aware that a solitary seedling having what we call single flowers was saved during the whole of that time. It was much the same with Dahlias; only double-flowered varieties were saved from the holocaust of the florist's fancy. No Herod was ever so frantic a slayer of the first-born as has been the raiser of new florists' flowers. No man could, I feel sure, have helped botany and physiological research more than the florist had he so willed it, and I will venture to say no class of men has given it less real aid. Who shall tell us how long the florist blundered along "the Primrose path," saving the symmetrical thrum-eyed flowers and throwing away the long-styled forms, and yet he never, never even guessed the secret, that Darwin discovered, as to the sexual relation of these long and short-styled forms. The Arabs have a proverb, "He that hath great knowledge binds it as a napkin on his eyelids; but to the humble and reverent are all things revealed;" and so of a truth has the knowledge of the florist been as a mote to him in the development of the Chrysanthemum. As a proof of this, the Dahlia has been taken out of his hands by the public, who insist on having single forms, not to the exclusion, be it noted, of double kinds, but as an addition to them. And now the public insist upon having single or Daisy-flowered Chrysanthemums, single Pyrethrums, single Camellias, single Ranunculuses, and single Anemones. I do not say that the florist has been altogether wrong, but that his "criteria" were too narrow and his sympathies too restricted is generally admitted. Let us hope the day of globes and circles, the cart-wheel type of beauty, is over, and that

we may grow the Chrysanthemum in all its forms untrammelled by the globular theory of beauty. An old friend said to me the other day, "I have often wondered why florists always favoured double Chrysanthemums and double Dahlias, while they repudiated double Tulips or double Auriculas." He did not blame them for growing their flowers in such forms as gave them greatest pleasure, but he blamed them as false prophets, who denounced all that floral beauty which, as a class, they could not themselves enjoy. We grant the florist his flowers, but we refuse his gospel of globe and circle, feeling that flowers of all kinds have a higher purpose than to be made artificial.

I have said so much because no other flower with which I am acquainted has suffered from the florist's labours as has this our favourite Chrysanthemum. Now, however, it is pleasant to know that we have growers who, as just stated, are most anxious to secure single or Daisy-flowered kinds bright and rich in colour. This is quite a new field, and a most fertile one, nor need it lead to the exclusion of the more plethoric varieties, whether of the Chinese or Japanese races. Speaking to a large grower of single-flowered Dahlias the other day, he told me that the advent of the single varieties, so far from supplanting the double kinds, had actually increased their sale, and we have no doubt that single Chrysanthemums will, instead of superseding the double kinds, only help to make them even more popular than at present, just as foreign imports of fruit and vegetables lead to a greater home production of the same products.

Our plate represents three new varieties, none of which we believe come under the florist's standard, but which are sufficiently distinct and effective to merit the attention of ordinary cultivators. No. 1, Tisiphone, is perhaps the first single Chrysanthemum ever honoured with a coloured portrait, and may be taken as an example of the Daisy bloomed Japanese section which is likely to become as popular as single Dahlias themselves. I have often wondered whether specimens of the typical or wild Chrysanthemums of China, Japan, and Corea are preserved in the herbarium at Kew, or whether cultivated varieties of this popular flower only are known. At any rate the variety which first bloomed in Colville's nursery in the King's Road, Chelsea, in 1795, and which is figured in the *Botanical Magazine* for February 1, 1796, t. 327, is a fairly good double variety of a reddish purple or claret colour; indeed not at all unlike the modern variety grown under the name of Dr. Sharpe.

No. 2 of our plate, Ringleader, belongs to the hybrid or large-flowered Pomponé class with reflexed florets of a deep rosy hue. No. 3, Orange Beauty, is a soft yellow bloom with a conspicuous greenish eye. It is floriferous and distinct enough to merit general culture, but none of the forms figured will, as we imagine, be claimed by the florist fraternity as belonging to their standards of perfection, and yet the Chrysanthemum is capable of far greater diversity of formation and colour than is here shown. Amongst a batch raised last year from seed we had some remarkable single varieties—one not unlike *Senecio pulcher*, with purple florets and gold disc, and another not unlike this Tisiphone, but of a mere bronzy hue, which was much admired. These three new varieties were raised by Mr. Alfred Salter, our drawing having been made in Messrs. Veitch's nursery, Chelsea, during the past

season. We must ask Major Carey and Mr. Downton, the raiser of Elaine, to save us some of their brightest and best Daisy-flowered seedlings, and so inaugurate a new departure in the history of the Chrysanthemum.

The summer-blooming race is especially valuable for open-air culture, blooming, as they do, long before frosts come to destroy their beauty. From this early race great things may be expected, and every year brings forth better varieties. I shall not soon forget the effect produced in Ware's nursery last October by Adrastus (rose or lilac-purple) La Petite Marie or Little Mary, with button-shaped white blooms; and last, but most beautiful of all, Madame des Grange, a large, soft, white flower with sulphur centre—a flower not inaptly described as a summer blooming or hardy Elaine. Maize is another soft white flower of this race, larger than usual and most useful for early autumnal blooming indoors.

By special culture alone much may be done to extend the winter season of the Chrysanthemum, and growers are now on the alert to select the kinds best suited for late blooming, January being perhaps the month in all the year when flowers are most scarce, and so most valuable. Ethel, Fleur de Marie, Mrs. Charles Carey, Meg Merrilees, and Peach Venus are all good late blooming kinds; indeed, of the last named really good, well-coloured blooms were sent to THE GARDEN office as late as May during the current year. The especial points to which improvement may be best directed, however, seem to be as follows: 1, good single flowered kinds of rich distinct colours; 2, late blooming kinds which will give a supply of flowers during January and February; 3, early or summer blooming varieties, with large blooms of the single Chinese or Japanese type.

Seeing that the Chrysanthemum is every year becoming more popular, it is to be hoped the secretaries of societies will do their best to foster its improvement, and more especially by holding out inducements for the exhibition of distinct new seedlings, even although they may not quite agree with the hard and fast rules long ago laid down by Mr. Glenny and other florists of the old school.

F. W. B.

SEASONABLE WORK.

FLOWER GARDEN.

GOLDEN MONEYWORT.—This is a yellow-leaved sort, obtained from the common Moneywort which grows wild in British meadows; hence it may justly be classed as a weed, but it is also an excellent plant for moist and shady places in the rock garden, and for carpeting the ground beneath the taller plants, the appearance of which is improved by an undergrowth of deep golden yellow, a colour which this plant retains throughout the season. We have used it for edgings and groundwork in the open flower garden, but, being a shade-loving plant, it gets rusty in bright, sunny weather, and is therefore not to be relied upon for such positions—at least not in the southern counties; northwards it would no doubt prove as useful for this purpose as it does in the south for undergrowth and rockwork. It is readily propagated by division at any season of the year.

SHRUBBERIES.—Owing to the multiplicity of operations that at this season demand attention, shrubberies are apt to get neglected, and Nettles, Thistles, Dandelions, and other weeds allowed to run to seed. Of course, this only happens in places where labour is restricted, and where something must be left undone; though, taking into consideration the after consequences, such weeds as these should not be overlooked, for even if time

for hoeing or hand-weeding cannot be spared, they may very quickly be prevented from seeding by roughly going over them with a rip-hook till such time as proper attention can be devoted to the work; then the plants should be cleared of all seed vessels and dead branches, irregular growths shortened back, and suckers removed. Clematises and other climbers should be secured to their supports. Ordinary Pea sticks, placed in a slightly leaning triangular form, make excellent supports for shrubby climbers. Lately moved plants should be re-mulched, and if necessary soaked with water. Turf verges should be closely cut, and any vacant spaces near the front planted with such biennials as Snapdragons, Canterbury Bells, and Sweet Williams.

MIXED FLOWER BORDERS.—The most showy and most useful flowers on our borders at the present time for vase furnishing are Pyrethrums and Columbines, the yellow and bronze coloured flowers of the latter being the most novel and pleasing. The Pyrethrums, both single and double, range in colour from deep crimson to pure white, and in a cut state keep fresh for a longer period than any other flowers with which we are acquainted; their merits are such as to justify their extended culture. These and many others now need staking and tying, but it should be done as loosely as the safety of the flower-stems and plants will admit of. Weeds should be kept down and the surface-soil broken, particularly about Dahlias, Hollyhocks, and sub-tropical plants lately planted for autumn effect. Old-established plants do not need these details of culture; indeed, many thrive best when left for years in an undisturbed state, or with only such attention as to curtailment of growth as shall prevent their injuring adjoining plants. As is the case with many plants this year, Asters, Stocks, and Phlox Drummondii are suffering from the attacks of aphides; they should therefore be syringed with soap-suds two or three evenings in succession, and then well washed with clear water. Owing to the dripping weather, slugs are also extra active, especially amongst annuals; the best bait for them is bran, to which they go readily, and may be caught in the act of feeding any time after dusk or very early in the morning. Plenty of soot and lime thrown about does much to keep them at bay, but rain soon renders both inoperative, hence my partiality for the bran baits.

GENERAL WORK.—This consists in pegging down bedding plants and freeing them from useless flowers, mulching with Cocoa fibre the smaller plants, and keeping the ground about the larger kinds open by frequent stirring. Calceolarias, Violas, and Verbenas enjoy a rich mulching of cow manure or horse droppings; such coverings keep them in vigorous growth and bloom during the hottest weather. Clipping edgings and groundwork of Sedums, *Herniaria*, *Mentha*, and the like will also now be engaging attention, also turf edgings and verges, mowing, weeding, and after rain rolling walks.

INDOOR PLANTS.

CLIMBING ROSES.—Where Roses are trained on the roofs or back walls of conservatories or greenhouses they are often found to thrive well for a few years and then to get into a stunted, weak condition, making little growth, and equally unsatisfactory in flowering; frequently the cause of this is an insufficiency of manure regularly applied as the roots exhaust it. When Roses are grown under glass, the extra warmth they receive, and the consequently much longer period in each year they are kept on in a growing state, tend to tax the roots proportionately more, and unless the soil is kept constantly supplied with the requisite enriching materials the growth necessarily becomes weak, rendering the plants an easy prey to insects that invariably attack weak growth. Another cause of insufficient bloom is the want of enough thinning out of the weak shoots, whereby the energies of the plants, instead of being directed to the support of a moderate number of shoots that would grow to a size able

to produce a crop of flowers, are spent in the production of weak, useless wood unable to bloom. Roses when grown indoors, as they are in the open air, are gross feeding plants, that, moreover, generally are subjected to a free use of the knife, and to avoid their getting into the condition described must have very much more manure given them than would be sufficient for almost any other kind of plants cultivated under glass, and after the principal flowering is over they should have all the useless wood cut out and a considerable portion of the old strong shoots annually well shortened back; in this way they make through the summer new wood that will not fail to flower the ensuing season. With that favourite climber *Maréchal Niel* it is more necessary to follow this treatment yearly than in the case of most others. One of the most successful growers of this variety, who has the roof of a very large house completely covered with several plants, cuts them all back each spring after blooming almost as close as Vines in winter after they are pruned. As regards this splendid Rose, under all conditions, either where grafted, budded, or on its own roots, it is so short-lived, that it becomes necessary to put in young plants at intervals of three or four years, so that they may take the place of those that go off. In winter, before growth begins, is the best time to add new soil and manure, but where the plants are at all weak they should now at once be assisted by heavy top dressings of manure, over which for appearance sake 1 inch of fine soil may be spread; this will be washed down to the roots in the process of watering, which, with diligent attention as regards keeping them clear from insects, will maintain the requisite strength.

PELARGONIUMS.—Zonal varieties wanted for flowering in winter should be so treated as to insure the pots getting well filled with roots, and the whole growth thoroughly matured before autumn; this is of much more consequence than studying to get the plants large, as if at all in a soft, over-vigorous condition they will run off to leaf-growth as soon as subjected to warmth in place of flowering. To avoid this, all young stock for winter blooming should be at once moved to the pots they are intended to occupy and free growth encouraged, after which they ought to be placed out-of-doors in an open situation under the full influence of the sun, and kept there until there is danger from frost. The earliest flowered portion of the stock, such as the London market growers cultivate, should as soon as they have bloomed be fully exposed out-of-doors, so as to ripen up the growth previous to heading them back; if this be done in good time they will break into growth, and can be repotted sufficiently early to admit of their gaining the needful strength before autumn.

SALVIAS.—These, if grown in pots, ought to be moved into those they are to flower in; the size the plants are required to grow to will determine the amount of root room they should have. The pots ought to be plunged in ashes, choosing a position where they will be sheltered from rough winds, but still where plenty of light will reach them; stop the shoots as often as may be found necessary, and never allow the plants to want for water, otherwise the foliage is sure to be injured.

AZALEAS.—The growth of these must now be regulated. If those that flowered first are wanted to bloom next season earlier than hitherto, and the buds are not yet prominent, they must be kept for some time longer in a house or pit in which a close atmosphere can be secured in the after part of the day by closing the ventilators early. Such plants as bloomed later should now be encouraged to make growth by placing them where a sufficient temperature can be kept up. Syringe freely every day when the house is closed to keep down thrips, and if these or red spider cannot be kept under by syringing with clean water alone, the plants should be dipped or syringed with Tobacco water, which, although taking more time than fumigating, is nevertheless much preferable, as we have never been able to use as much Tobacco smoke as would destroy the thrips without injuring

the leaves. All that have bloomed late and are in want of more root room should now have a shift. Azaleas do not begin to make root until after they have pushed a good amount of shoot growth, and just after this has commenced is much the best time to pot them. They do with considerably less root space than most hard-wooded stock, but like to be encouraged either with manure water or some of the concentrated manures now so much used.

OLEANDERS.—The individual blooms of these easily-grown plants much resemble those of perpetual-flowering Carnations, and are little inferior to them for cutting, a purpose for which they are in every way adapted. Their erect habit of growth is somewhat against them, but where large, well-furnished specimens exist with suitable treatment they can be turned to good account. Large examples of this description should now be placed out-of-doors in a sunny position, where their further growth will be somewhat checked. If treated in this way and supplied with water enough to enable their bloom-buds to set, shoots taken off with about half-a-dozen joints will strike readily and make nice flowering stock in 5-inch or 6-inch pots. Young plants propagated from small shoots and grown on in little pots should now also be fully exposed to the sun in the open air. Unless Oleanders are so managed there is no way of insuring their blooming satisfactorily, as they keep on growing and do not get their growth properly ripened. Medium-sized examples that have bloomed late and that are required to be kept low and bushy may now be well shortened back, and as soon as they have broken afresh should, if necessary, receive a shift. They will thrive in any kind of soil, but moderately strong loam seems to encourage a disposition to flower.

CAMELLIAS.—The earliest flowering plants are best grown in pots, as thus treated they can be moved about as occasion requires in order to accelerate or retard their blooming. Any that have already got their buds as far advanced as may be desirable should be placed in cooler quarters, but until in this condition they must not be moved out of warmth, as when once the excitement consequent on their being in heat is stopped they will not bear forcing subsequently; therefore, it is well to note their condition. All that had their growth retarded by late flowering should have sufficient shade to protect their young tender leaves from sunshine. Syringe freely once a day, and see that the roots are kept well moistened, a matter to which it is necessary to pay particular attention.

TABLE PLANTS.—Plants naturally fit for use in this way are by no means plentiful. As a rule those disposed to keep to a single stem, such as the smaller leaved *Aralias*, *Palms*, *Dracenas*, and others of a like character, are the most suitable, and when too large for this purpose there should always be sufficient successional stock to take their place. Amongst *Pandanus*, *P. Veitchi* is most liked; where plants of it are nicely variegated and not too large it is very effective, but, owing to its being unable to live out of heat except in summer, it is not so useful as others more hardy. It is, however, easily increased, as it produces suckers freely when it has attained a moderate size. It is not well to allow the suckers to get too large before taking them off from the old plants, as if their leaves have got long and erect they never make such good examples as when struck small. Suckers will root freely treated in the way in which *Pines* are managed; slip them off from the parent plants, strip a few of the bottom leaves off, and insert them in small pots filled with ordinary loam, with or without bottom heat. There are one or two other species that answer well for this kind of decoration whilst in a small state, of which *P. javanicus* variegatus and *P. Vandermeerschii* are the best; they require similar treatment to *P. Veitchi*.

CUTTING BACK HARD-WOODED PLANTS.—There are some hard-wooded plants that require a free use of the knife every season immediately after they have done flowering, otherwise they

soon get into such a loose straggling state as to be worthless. Amongst these are *Polygalas*, *Pimeleas*, *Dracophyllum gracile*, *Epacris*, *Tetratheca verticillata*, *Diosmas*, *Correas*, *Acacias*, and others possessing a similar habit—plants, in short, that annually make shoots of considerable length, and which if a good part is not well cut back, cannot be kept within bounds. From one-half to two-thirds the length of shoots made last summer should be removed, after which the plants ought to be encouraged to make growth by placing them in a house or pit where they can be kept closer than in an ordinary greenhouse, and be syringed overhead in the evenings.

SOLANUMS.—The berry-bearing kinds of these are most useful when managed so as to induce them to come on in succession. If a portion of the stock has been treated as already directed, they will now be furnished with fruit that will have sufficient time to become fully coloured by the end of September, from which time to the close of the year they are most serviceable for associating with the comparatively few flowering plants that can then be had in bloom. Those later in flowering will follow the first, and if well attended to, will colour their berries towards the close of the year. To have these *Solanums* in presentable condition, their leaves must be in a healthy green state, as if at all deficient in this respect they are uninviting in appearance; to insure this, as the pots are now full of roots, they must have unremitting attention in the way of supplying water, and they should also have liquid manure once a fortnight.

KITCHEN GARDEN.

THE cutting of *Asparagus* must soon be stopped, and the beds will be much benefited by a good soaking of manure water. Beds that have been much cut should now be encouraged by every means to make good growth, for on this depends their ability to keep up in years to come their producing powers, both as regards quantity and quality. *Asparagus* often gets worn out much sooner than it otherwise would do through suffering neglect after cutting has ceased. Advancing crops of Carrots should be again looked over to see that they are not left too thick, especially the main sowing. Turnips also will require attention in this respect; there are few crops suffer so much as this if allowed to stand too close together, as when in this state they run to leaf, forming bulbs that are not only small, but very poor in quality. Thin the main crop of Beetroot before the plants get so large as to interfere with the growth. Some Colewort seed should now be sown; these will be useful for planting thickly late in the season after other crops are cleared off. Where dwarf French Beans are held in particular estimation a few more may at once be sown; these should occupy a south border, under the shelter of a wall, where, by a slight additional protection from September frosts, they will frequently go on bearing longer than those grown on more open situations. Autumn-planted Cabbages that have been cut and the stools left to produce a crop of Sprouts should, where the land is at all poor or of a light character, have a good soaking with manure water, by which, in addition to thinning out the shoots to some two or three to each stool, they will make small useful heads, that will come in through the autumn. Keep the hoe going on all favourable occasions amongst advancing crops of every kind.

FRUIT.

VINES.—When all the Grapes have been cut from the early Vines, examine the inside borders, add a little fresh mulching if they have suffered from the weight of the crop, and keep the roots moderately supplied with diluted liquid to start a flush of laterals, but guard against carrying feeding to an excess that will force a vigorous growth, and so exhaust the Vines after the wood is ripe. Keep the strongest laterals pinched to balance the flow of sap, and preserve all the old foliage by good

syrring every evening, or as often as the state of the weather may render atmospheric moisture necessary.

SUCCESSION HOUSES in which the Grapes are ripening may have more air by night and by day, with just sufficient fire-heat to keep the minimum temperature at 60°, and when the berries have attained their full size, the afternoon closing may be discontinued, particularly where the colouring process is not going on satisfactorily. If this house contains Madresfield Court Muscats, see that the borders are moist, but not wet, mulch well with some loose non-conducting material, and allow all the laterals and leaders to grow until after the Grapes are cut. The biting north and east winds having kept the external temperature so low as to necessitate sharp firing, spider has become more plentiful than agreeable, and so rapidly does it spread under the bright and now powerful sun that vigorous measures must be taken for keeping it in check. As almost every one dreads the use of sulphur, timely sponging with soapy water, the application of clean soft water through a good syringe every night where it can be applied without touching the Grapes, and generous culture, separately or combined, while helping the crop will tell most decidedly against the enemy.

LATE HOUSES.—Muscats, Lady Downes, and other kinds which frequently scald during the stoning process must be closely watched until they are considered safe. Up to the present time the weather has not been too warm, and constant firing to maintain a medium temperature has been favourable to the Grapes, as we have not had sudden fluctuations; but any rapid change or disturbance of the atmosphere may bring on the usual fermentation of the pulp surrounding the kernels, in which case it will be well to continue a high night temperature, with diminished atmospheric moisture to prevent the berries from getting cold, and to maintain a steady heat of from 76° to 80° through the day, by keeping the pipes warm, and by increasing or decreasing the ventilation.

MELONS.—A few seeds of favourite kinds may still be sown and grown on in pots for filling up the different compartments in which fruit is now swelling off and ripening. All the green-fleshed kinds do best when plunged in fermenting material placed over the bottom-heat pipes, as the roots are then entirely under control, and a flush of fire-heat when they are in flower will always insure a good set, and a continuous circulation when the fruit is ripening will greatly enhance the flavour. For standing on kerbs in Pinestoves, or where it is inconvenient to plunge, we always give preference to scarlet-fleshed kinds, as they can stand more dry heat and are less subject to red spider. They, however, require more feeding from the first, and to counteract the drying influence of hot-water pipes over which they are often placed, shallow trays made of wood and about 2 inches deep are placed under the pots for the reception of a few handfuls of rich compost and the partial retention of liquid manure as it passes away from them. We mention trays advisedly, as roots ramify and feed better in them than they do in saucers in which the liquid remains and soon becomes stagnant. An old Melon grower has said that all Melons are good when properly grown, and he might have added three-fourths of the Melons now sent to our shows are so thoroughly changed in colour and character, that they cannot be recognised by their raisers. Change of colour is, of course, due to the presence of two or more kinds—perhaps not in the same house, but in the same garden—and deficiency in flavour may generally be traced to an excess of cold water about the roots through the swelling stage and want of bottom-heat when the fruit is ripening. If the grower of Melons would guarantee a true stock he must not grow more than one kind. If he would have his fruit always good he must hold the elements of heat, air, and water entirely under his command, and the latter condition is in no other way so certainly and easily secured as by the adoption of the pot system.

CUCUMBERS.—Where the bottom-heat is obtained from hot-water pipes and fermenting material combined, the latter should be renovated with fresh fermenting leaves when the plunging thermometer denotes a fall to 80°, and the night temperature of the house cannot be maintained without having recourse to sharp firing, at all times injurious to a moisture-loving plant like the Cucumber; but never more so than when the powerful midsummer sun strikes suddenly upon the roof before the pipes have had time to get cool. If the pots or beds are well drained it is hardly possible to over-water, or to give the foliage too much atmospheric moisture, provided the liquid for the one and the pure water for the other is applied at or a few degrees above the mean temperature of the house. As the plants will now be producing fruit at every joint, overcropping must be carefully avoided, at least if they are to be kept on bearing throughout the summer; but where they are shortly to be removed for Melons a flush of fruit may be taken before they are destroyed. Where manure is plentiful, and frames which have been used for forced vegetables are now at liberty, a few lights under good management will give an abundant supply of excellent fruit until the early autumn-sown plants come into bearing. Instead of pulling down and rebuilding the beds, we dig out a trench 2 feet in width, the whole length of the frame a little nearer to the front than to the back, fill in with a few barrow-loads of the best fermenting material we have at hand, and turn the plants out on small mounds of maiden loam. A new lining is placed to the front; we cover early every night, and adopt the market grower's system of shutting up about 3 p.m. with sun heat and plenty of moisture. If straight fruit is required, glasses may be used.

FLOWER GARDEN.

SOME USEFUL HARDY BORDER PLANTS.

ONE has only to take a walk in the garden in May to see of what use hardy plants are and what a wealth of floral beauty they afford at that early period, but many as there were in bloom then, their numbers are probably more than double now, a fact which shows of what great value they are either for making borders gay or for cutting. Among the more noteworthy the following deserve special mention:—

DAPHNE CNEORUM, although old, is still unrivalled among prostrate growing shrubs, forming dense masses of colour, as every shoot is terminated with clusters of rosy pink blossoms, exhaling a most delicious perfume. Where this Daphne seems most at home is trailing over rockwork, depending from banks, or other elevated positions, where, if the soil is suitable, it is sure to succeed remarkably well. Some have much difficulty in getting it to grow and in effecting an increase, but here it spreads freely and roots readily from layers. All we do when we wish to augment the stock is to partly bury a plant by covering the branches with sharp sandy earth; they then root in about a year, and in spring may be severed, lifted with good balls, and transplanted. Plants may also be obtained from cuttings, but that is a much slower process, as the pieces taken off must necessarily be small, and it is some time before they get to any great size. *Phlox Nelsoni* forms a capital companion plant, and being of a trailing nature is well adapted for the same kinds of situation, where its profusion of starry flowers are shown off to the greatest advantage. To plant near the *Phlox*,

LITHOSPERMUM PROSTRATUM should not be forgotten, as blooming at the same time, which it does, and having flowers of as rich and deep a blue as a Gentian, the effect is most charming. As its specific name implies, it is of prostrate or procumbent habit, and only lifts its slender branches a few inches from the ground, which, where the soil suits it, it covers with a thick carpet and blooms profusely from all the young

growths. The way to propagate it is to take cuttings from the half mature shoots and insert them in sharp sandy peat pressed firm, when they should be covered with a bell-glass or handlight, and kept shaded in a cold frame or north border till rooted.

ALSTROMERIAS are now opening and will soon be at their best, and, taking into consideration how exceedingly showy and lasting they are, the wonder is that they are not more cultivated, but this may be through people having failed with them, owing to planting them where the position was not warm enough, or the soil sufficiently light and well drained. To be successful with them and grow them well they must have a sunny border sloping to the south, and if close under a high wall or fence so much the better, as not only are *Alstromerias* apt to be injured by frosts in winter, but they are very liable to have their young tops cut by cold winds in the spring, as they are out of the ground early and rather tender when they first make their appearance. The way to prepare for them is to trench the ground deeply and add plenty of leaf-mould and sand, when the plants should be planted, if dormant, 6 inches beneath the surface, and if growing as much below as the tops will allow, which enables the tubers to strike down and keep out of the grip of hard frost. A good plan of starting with *Alstromerias* is to sow seed scattered thinly, and covered about an inch deep, which should be done where the plants are to remain, as they cannot well be transplanted. One of the most striking subjects in herbaceous borders at this time is

ANTHERICUM LILIAGO, which has very strong, tall branching spikes of white flowers with dark stripes up the petals. Anyone wanting a plant for naturalising in the wild garden, or planting in the foreground of shrubs, or by the side of water in conspicuous places will find this just the thing, and, being a strong grower, it is quite able there to take care of itself. The mode of increase is by division, which may be effected any time during the winter or spring, when it may be cut through and pieces removed by the aid of a spade. Another plant that lends itself to be treated in the same way and suitable for similar positions is *Solomon's Seal*, which, from its gracefully arching stems, laden with silver coloured bell-shaped blooms and covered with delicately tinted pea-green foliage, is always a striking and pleasing object wherever placed.

THE DAY LILIES, too, especially *Hemerocallis flava*, which has heads of showy yellow flowers almost as large as *Amaryllises*, are remarkably fine, and should be in every garden of any size and pretension, as they make a grand show. *H. Kwanso* is a very strong growing variety, having rich brownish coloured blooms, and there is also a beautifully variegated form of the same kind that has much white in the long broad leaves, which in a young state are very nice looking, and plants of it are quite worth growing in pots. Where these Day Lilies do best is near water or in damp soil, where they soon attain a large size, and have a striking appearance.

PLANTAIN LILIES (*Funkias*) are also plants of noble aspect, the most remarkable among them being *F. Sieboldi*, a kind that has magnificent foliage, as not only is it large and Palm-like, but the colour is quite unique, being of a bluish tint of green and the surface glaucous. The beauty of this *Funkia* does not end here, as it sends up stout flower-stems which bear blooms in shape like those of Lilies, and the smaller sorts, like those of *F. ovata*, are very useful for cutting. To see *F. Sieboldi* at its best it must be planted in deep rich soil, where it can have partial shade and plenty of moisture, which bring out the peculiarities of its fine leaves, and enable them to attain their fullest development. *F. ovata* is best for borders, where, in early summer, the variegated section, of which there are many, have a choice and distinct appearance.

PÆONIES, both tree and herbaceous kinds, are simply grand, their large, full flowers so richly coloured being gorgeously beautiful, and producing a striking effect when seen in borders backed

up by low-growing shrubs, a position for which they are specially adapted, and the tree varieties also look well standing as single specimens on lawns. The way to propagate these latter is to graft them on pieces of roots of the herbaceous sorts, which should be done in the spring, when, if the grafted plants are placed in close gentle heat they soon start and unite, and may then be planted out in the open. All the herbaceous varieties admit of ready increase by division, the time for effecting which is just as they are beginning to grow, as then any wounds made by severing the parts quickly heal over instead of rotting, as they are apt to do if the plants are interfered with when they are dormant.

COLUMBINES are quite a host in themselves, there being now so many kinds, and most lovely some of them are, my favourites being the soft canary coloured *A. chrysantha* and the large and distinct *A. corulea*, which, being of a beautiful shade of blue, contrasts well with the other. Unfortunately, the last named is not a very good grower, and many lose it through the soil not being light and suitable, and not sowing sufficiently often; to make sure of good flowering plants, it is necessary to treat it as a biennial, but *A. chrysantha* will stand for years and get strong. What affects this variety injuriously is the cold winds in spring and late frosts, to avoid which it should be planted in sheltered spots and somewhat dry elevated positions. *A. glandulosa* is a fine robust sort, as are likewise most of the hybrids, and many of these and the original vulgaris may be easily naturalised by the sides of woodland walks or other semi-wild places, which they help much to enliven, and where they look quite at home. The way to start with them is to clear patches of ground here and there and plant strong plants, which will then seed about and continue to spread, as they are well able to hold their own with the weeds and Grasses around.

GENTIANA ACAULIS is, and has been, most charming, lines of it being thickly studded with its upturned blossoms of blue, which open and close as the sun shines and sets. Patches of this Gentian are all very well, but to see it in its glory a long row of it is wanted, and the place for that is along the side of a walk as an edging or a margin to a border, where if the soil is tolerably deep and cool it grows well, especially if planted between, partly buried, large flint or other stones, which hold the moisture and entice the roots round them. With care in watering, and by shading a little after their removal, Gentians may be divided and planted now, as under such favourable conditions they soon get fresh hold and start off again.

PYRETHRUMS are at present the gayest of the gay, the colours being rich and varied, and the flowers of the double sorts as large and full and well formed as those of French Asters. The single kinds are also likely to come into great favour, as they are light and elegant in outline, and the ray florets exceedingly bright and effective. To grow Pyrethrums well they must have good soil where they can send their roots down, and find plenty to feed on.

ANEMONE FULGENS and coronaria have been superb, beds of the latter being a mass of blooms, which have gone to seed, and this, if not picked when ripe, is soon scattered broadcast by the wind and distributed all over the garden. Those who have not these Anemones should sow at once on a light, sunny border, for though this would have been better done sooner, the plants raised will bloom in the spring and afford plenty of flowers for cutting.

CAMPANULAS of various kinds are just opening, the most showy being the biennial species *C. calycanthema media*, plants of which make a splendid display, as they are full of big bell-shaped, variously coloured blossoms from base to summit. To have them strong and good next season seed should be sown now, and when up the plants pricked or planted out in rows to grow on for removal early in autumn.

DELPHINIUMS are fast sending up their spikes, and one or two are already open, the first to show

being the good old *D. formosum*, which will be quickly followed by the charming *D. Belladonna*, one of the best of the family.

IBERIS GIBALTARICA HYBRIDA is a mass of pure white, and the Irises, both bulbous rooted and common, are all aglow with their multitudinous spikes of grey blossoms, so curiously formed and marked, and so rich and lovely in colour, as almost to rival some of the choicest of Orchids, which they greatly resemble. It is only in light warm soils that the bulbous species do well, but the English Irises will flourish anywhere if they can find plenty of moisture.

S. D.

CATANANCHE CERULEA.

IN most gardens this plant is of annual or at most biennial duration only, but on warm sandy soils it

Catananche cerulea.

now and then becomes truly perennial and of great beauty as a late summer-blooming plant of distinct habit and ornate character. The plant has long been known in English gardens, since we find a good figure of it in the *Botanical Magazine*, t. 293, and we are there told that it comes naturally from the south of France, "where it grows in hilly situations that are stony. It is a perennial herbaceous plant, moderately hardy, and has long been cultivated in our gardens, Mr. Aiton says, by Parkinson in 1840." Miller treats of it in his dictionary, and yet it is by no means a common plant in cultivation. Another species, *C. lutea*, is interesting as a botanical curiosity, but it is by no means so showy as is the plant under notice. *C. cerulea* is easily increased from seed sown during the spring or summer months. The plants soon become strong enough to be planted out in the borders where they may remain until they bloom. Here in Dublin this plant is perfectly hardy, the only precaution we take for its safety being to put a little heap of coal ashes or sand around the collar of the plant ere it dies down

for its winter's rest. Large plants afford a good supply of mauve-blue flower-heads for cutting, and as an ordinary hardy plant for the outdoor decoration of bare ground it deserves more attention than it at present receives. F. W. B.

STOCKS FOR SPRING FLOWERING.

FOR the last three years we have had Stocks in bloom in April, May, and June, and they are so very useful then that their culture for blooming at that time is well worth general attention. In most places cut flowers are constantly in demand, and when Stocks are in bloom thus early they certainly rank amongst the most valued flowers one can get from open-air borders. Their bright and varied colours, and above all their sweet scent, delight everybody. They might be used in many spring flower gardens, and where there is no place for them in such positions they might be grown in the borders of the kitchen garden or in shrubberies; indeed, when in bloom they can hardly be out of place anywhere. The varieties most suited for spring and early summer blooming are the Emperor, Brompton, and the Giant Cape. Seed of these should be sown about the end of July in a bed or row anywhere. It should be sown thinly and covered over with about an inch of soil. The young plants will soon come up and grow fast in August and September, and in October or November they should be transferred to their flowering quarters. If sown and grown thinly in the seed bed they will not become too crowded before planting, and they may be drawn up on a wet day and dibbled in where they are to grow. Previous to planting the ground should have been dug up, and in doing this if the soil is poor it should have a good coating of manure added to it, and soils of all kinds should always have a dressing of soot worked into them before the Stocks are planted. This prevents them from being destroyed by maggots at the root—a common occurrence, and troublesome in many parts where precautions of this kind are not taken. When planted they will take care of themselves through frost or snow and all weathers, but if a few have been left in the seed bed, they may be used to make up blanks in March. In that month the plants will begin to grow, and then the Dutch hoe should be run between them. After this growth will go on rapidly and flowers will soon make their appearance. In all Stock beds there will be single and double flowering plants; the single flowering kinds some dislike and pull them up, but this is a mistake, as single sorts are just as pretty as the double ones, and in a mixed bed or border they are equally effective; besides, it is an easy matter to save seed in autumn from spring-blooming stocks, and in many instances it would pay to allow the single ones to remain in order to secure this object. One thing is certain: nothing can be more easily grown than Stocks to flower in spring, as their culture is all in the open air, a circumstance which alone ought to secure for them the attention of all who have a garden and who love bright-coloured fragrant flowers.

J. MUIR.

Exhibiting alpine flowers.—My reply to "Peregrine" (p. 529) shall be very brief, as I decline controversy with people who do not sign their names, and yet profess to know a great deal more than those who do. I have shown that the *Auricula* is not forced. It blooms naturally at the time fixed for the shows; and, to prevent forcing, the rules are enforced that there shall be no artificial supports. It should be practically the same in exhibiting alpine and hardy plants. If a show is fixed for May the plants should be selected accordingly, and there are quite plenty of suitable ones to be had which require no forcing. If a show was to be in August, you would select autumn plants. I have had a pretty large experience, and know that it is perfectly practicable to make a good display of plants in proper character. I should be sorry to show a plant otherwise. If, however, a fashion obtains, and is encouraged by the judges, of showing plants in May,

taken from the whole range of the seasons, and you have to force plants such as *Pæonies*, *Phloxes*, *Campanulas*, *Pentstemons*, and other midsummer and autumn bloomers, and crowd huge lanky specimens out of all character and merely true to name into your thirty or forty plants, I say such an exhibition does harm, and is unworthy of any society whatever which has the real good of floriculture at heart.—WM. BROCKBANK, *Brockhurst*.

5008.—**Violets in September.**—Violets would be rather unseasonable in September, but we have had the Neapolitan producing a few stray blooms at that period. During my experience of their culture I have found them extremely capricious. One time I considered myself foremost as a Violet cultivator, and I believe I was the first to exhibit them in London, and was highly congratulated on having produced what had not often been seen before. The past two years, in a different locality, has convinced me that I owed much of my success to local circumstances. My stock of the Neapolitan and Marie Louise consisted of a dozen of each two years ago, and they number about the same now. The Czar we manage satisfactorily in frames. It would be interesting to know where in Lancashire one could see three or four kinds of Violets well grown. Perhaps some one will kindly supply the information.—W. P. R.

Hairbell and Bluebell.—Concerning this subject there seems to be two almost insuperable difficulties: 1, whether *Hair-* or *Harebell* is the correct orthography of the word; and 2, that being satisfactorily settled, to which of the two plants, *Campanula rotundifolia* or *Scilla nutans*, is the name to be applied. The subject was pretty fully ventilated in "Science Gossip" during 1881, with the result that we were left at the conclusion about as wise as we were at the beginning. If *Hairbell* be the proper mode of spelling, then evidently it can only suit the *Campanula*, as it would require a very vivid imagination to see any resemblance to hair in the *Scilla*. If, on the other hand, *Hare* be the way in which it should be spelt, then the difficulty as regards settling the matter is greatly increased. "A.H." (p. 523) seems to have settled it satisfactorily to himself, but I fear that others will scarcely be so easily satisfied. He is probably right in regard to the *Hairbell*, but when he speaks of *Agraphis nutans* being the *Bluebell* of Scotland, and *Hyacinthus non-scriptus* the English *Bluebell*, one is amazed at the easy way in which he disposes of the subject. These two names are (according to Hooker's "Student's Flora") synonyms for the same plant, *Scilla nutans*, so that "A.H." makes the Scottish and English *Bluebell* exactly the same. This may be desirable for the sake of simplicity, but it is scarcely according to fact. In Scotland the *Campanula* is almost universally called the *Bluebell*, while if the name be applied at all to the wild *Hyacinth*, it is always distinguished as the English *Bluebell*. The white variety of both species, although not plentiful, is found occasionally in this locality. Only last week I saw about a dozen white *Scillas* growing among a quantity of their blue-flowered companions.—W. McL. B., *Carlisle, N.B.*

Lilies of the Valley for market.—Allusion has been several times made in THE GARDEN to the excellent way in which Messrs. Hawkins & Bennett, of Twickenham, grow Lilies of the Valley for market. Under their culture the spikes of bloom of the Victoria variety, the kind which they grow, reach a height of from 12 inches to 14 inches, the bells being very large and handsome, and of the purest white; the leafage is also wonderfully robust; in fact, in this variety, under this firm's cultivation, Lilies of the Valley are seen in the finest possible form and in the highest development of beauty. None of the roots are subjected to forcing, but are grown in huge beds in the open, and in defiance of the assumed need for shade on the part of this Lily. All the earliest are obtained from plants growing on a broad south border, the warmest position in the place. Early in the year these beds are edged with boards, and over them lights are laid, to protect them from the weather and induce earlier growth. The latest beds are found behind the plant houses, and these

get no covering, but throw up bloom naturally. In this way the season of bloom lasts for some two months, and during that time immense quantities of spikes are gathered and sent to market. It is a peculiar property of the Victoria kind that, owing to its stout stiff habit, the spikes of bloom keep fresh and erect after being cut for a long period, and are readily purchased by bouquetists and floral decorators, because of their many good qualities. The beds seldom remain longer than six years untouched; they are then broken up, the finest crowns selected for new blooming beds, and the smaller ones make nursery beds; but so robust is the average character of the crowns throughout, that very small indeed is the percentage of them that are unfit for the blooming beds. The soil, when new beds are formed, is well prepared, and there is no stint of manure. Still farther, each bed gets in the autumn a top-dressing of rotten manure, and through this in the spring the crowns burst, full of strength and vigour.—A. D.

KITCHEN GARDEN.

CARDOONS AND THEIR CULTURE.

CARDOONS, though grown only in great gardens, are well worth a trial wherever a piece of ground can be spared for them. The blanched stalks of the inner leaves are put into soup, and when cut up fine they may also be used in salads during autumn and winter. On the Continent Cardoons are grown more extensively than with us.

THE SEED for the earliest crop should be sown in March, either in pots or boxes filled with light, rich soil; sow thinly and cover with some of the same soil as that in the pots; then place them in a warm house or pit. After the young plants appear they must be kept as close to the glass as possible. When furnished with two or three leaves place them in a cold pit or upon the shelf of a cold greenhouse until large enough to handle, when they may be pricked into boxes or into a prepared bed in a cold frame, where they may remain until they have become large enough to be planted into a prepared bed of rich soil; there they may be left until ready to plant in the trenches in May. The general or main crop sowing may be made the third week in April; choose a warm, sunny border, and enrich it with rotten manure or decayed leaf-mould. Sow either broadcast upon beds or in drills 6 inches apart and 1 inch deep, thinning the young seedlings out to 3 inches apart in the rows. If sown broadcast rake the seeds well into the surface with an iron rake. When the seedlings are large enough to handle, thin them out to 4 inches apart, when they will grow short and stocky. When left thick in the beds they become drawn, and seldom make good plants when put out into the trenches. They will be large enough to plant out in seven or eight weeks from the time when the seed is sown, provided proper care has been taken of the young plants. Sometimes trenches are made and the seed sown at the same time at distances of from 18 inches to 2 feet apart, thinning out the seedlings singly. The soil most suitable for Cardoons is a light mellow loam not over rich.

THE TRENCHES should be made the same as for Celery, but wider apart, a good distance being 6 feet, and they should be 18 inches deep and the same in width. Dig some rotten manure into the bottom of the trench, the quantity used being according to the richness or otherwise of the soil; if too rich, the plants are apt to grow too soft, and often hollow. The earliest plantation may be made about the middle of May, and the second, or main one, the last week in June or early in July, watering the plants well when planted, treatment under which they will be found to make plenty of young roots and to grow away satisfactorily during the summer, requiring little more attention except keeping down weeds and watering copiously in dry weather. In poor soil a dressing of artificial manure may be given once or twice, putting it in the bottom of the trench and forking it into the soil, watering well at the same time, or liquid manure may be used occasionally when the plants are in a young state.

BLANCHING is effected by earthing up the plants when nearly full grown, which will be from August till October. In performing this operation the leaves should be gathered together carefully and tied with strands of bast, or, what is better, lightly made haybands. When tied, earth up as is done with Celery, pressing the soil firmly round the plants as the work proceeds. If properly done the central stalks will become perfectly white. Continue the earthing up at intervals until the plants are moulded up to the top of the leaves, which should be some time in October. After that the plants will be blanched and ready for use in five or six weeks, and will keep good until spring, *i.e.*, if litter or dry Fern be placed over the crowns in frosty weather, or they may be lifted and stored in a dry shed or cellar free from frost, where they will keep in good condition for a long time. A good method of blanching Cardoons is to dig a pit 4 feet deep and 5 feet wide, and upon some fine day when the leaves are perfectly dry, dig up the plants and cut off the green tops. The plants may then be planted close together, but they should not touch one another. Make the pit any length which will hold the plants and cover it over with planks, over which put a thick coating of straw. In the course of a few weeks the stalks will be found to be finely bleached, and may be used as required. If they blanch faster than they can be used, they may be lifted and laid in a dry shed or cellar perfectly dark and free from frost, where they will keep good for six or eight weeks.

WM. CHRISTISON.

PEA PRODIGES.

ALTHOUGH this heading is very appropriate to the remarks of "J. S. W." (p. 527), it does not apply to anything I have written recently or at any time on Peas. It is well known that early kinds of Peas will grow in ground in which Marrows will rot, and I never knew anyone who said anything to the contrary when speaking of Peas sown in winter and the earliest spring months, but that has nothing to do with late Peas, to which my observations wholly referred. All kinds of Peas will grow freely in July, August, and September, and questions as to what sorts grow best then never crop up; but when it is desired that the pods should fill throughout October the question of hardiness arises, and all my experience and observation go to prove that late sorts are then the best and hardiest. When "J. S. W." affirms that "early Peas will endure the hardest frosts, which late ones are injured by," he gives information which is of no value practically, so far as late Peas are concerned, while had he furnished any proof that early Peas would go on filling their pods during the hardest frosts in autumn when the so-called late kinds were being injured he would have been doing something towards helping some one to secure late Peas. The low night temperatures generally experienced in October do not favour the fruitful development of any Pea, and when hard frost occurs one kind is just as easily injured as another. "J. S. W." is wrong when he says that no Pea has been found to surpass *Ne Plus Ultra* as a main crop or midseason variety. It is years behind many good kinds, and the very last I would think of advising anyone to grow now-a-days. I agree with "J. S. W.'s" suggestion that prodigies should be seen as well as heard of; no doubt many productions represented as prodigies would have been short-lived had this mode of dealing with them been put into practice. "J. S. W." need not, however, come here in August to see Peas, as we have no demand for them in that month, but if he likes to come in July I will be pleased to show him a few varieties of Peas such as he has never seen before, including a tall growing Pea which has podded profusely all over in four weeks less time than William I.

J. MUIR.

Margam, Taibach, Glamorganshire.

5009.—**Thrips on Cucumbers.**—Successive fumigation and frequent syringing are the most likely means to rid Cucumbers of thrips. The

syringing should be done with a fine rose or distributor, and the operator should aim at those parts where the thrips are most numerous. In this way I have managed to keep the same plants from nine to twelve months tolerably free from spider, and perfectly free from thrips.—W. P. R.

SOWING LETTUCES.

I SELDOM attempt transplanting Lettuces during the summer and early autumn months, as they do

rich and tolerably firm soil, and as our Potatoes do not quite exhaust the quantity of artificial and solid manures they receive, it follows that the Lettuces are also much benefited by them. Should the ground be at all dry at sowing time, the drills are first drawn, then well watered through a coarse rosed watering-pot, and after the seed is sown the soil is levelled. This plan of enclosing moisture with dry soil instead of watering after the seed has been covered is much the best, not merely for Lettuces, but for all other seeds. When the weather

favour of any hardy or so-called hardy green variety. Besides, the Brown Cos does not run to seed so quickly as the green or white varieties. Consequently, it should be sown regularly if only to secure a succession to any of the "superb," "mammoth," "incomparable," or "giant" selections of the Paris White Cos. W. I. M.

Summer Spinach.—One of the most delicious, and at the same time easily cultivated,

Yellow Dutch Cucumber.

Green Flesh Sugar Melon.

Wax Gourd (Benincasa cerifera).

Canadian Crook-neck Gourd.

Early Bush or summer Crook-neck Gourd.

VARIETIES OF GOURDS (see p. 559).

not succeed so well as those sown where they are to grow. This is especially the case on poor land. If there is abundance of good semi-rotten manure not deeply buried, but forked into the surface of the soil intended for Lettuces, they may be transplanted during hot weather, and will grow quickly and to perfection; but our garden is not well supplied with manure, and my plan is to make fortnightly sowings in two drills about 30 feet long, but in smaller gardens one quarter that length would be ample. No ground is given up entirely to Lettuces, as early in the season we plant or sow between the rows or intended rows of Brussels Sprouts and autumn Broccoli. Later on, say from the beginning to the end of July, according as the early Potatoes are lifted, and between which are planted Broccolies of various sorts, several rows of Lettuces will be sown. They are not greatly interfered with by the Broccoli, and seldom fail to prove most serviceable for autumn and early winter salads. Lettuces delight in a

is damp and the slugs troublesome, the rows of seedlings are occasionally dusted with soot or slaked lime, early in the morning being selected for the operation. When of good size and where the plants are at all crowded, they are lightly thinned out, and any blanks can a few days later on be made good by transplanting with a trowel. A distance of about 10 inches apart is ample for Lettuces during the early part of the season, but in the autumn 6 inches to 8 inches is sufficient. We generally sow two sorts each time, one always being the Black-seeded Bath Cos, which I consider invaluable, whether for spring, summer, or autumn work. It requires to be tied up to have it properly blanched, but when it is fit for use it is unequalled, whether as regards whiteness, crispness, or flavour. Brown Lettuces do not find favour in the markets, hence the introduction of hardy Green Cos varieties. With gardeners and amateurs the case is very different, and they will make a blunder if they discard the Brown Cos in

vegetables is the Round-seeded or summer Spinach but, singular to say, it is not grown nearly so much as it ought to be. It is regarded by most people as a luxury only to be enjoyed by the rich, but any one who has a garden and can grow Potatoes or Cabbages may have a supply of tender succulent Spinach, the only difference being attention to keeping up successional crops. Little and often should be the rule as regards sowings. We get abundance of it by drawing broad shallow drills between rows of Peas, and as soon as large enough the leaves are cut wholly off, and the crop finished at once, as it soon runs to seed. However, by sowing a little about every alternate week we have no lack of Spinach. During the months of July and August a shaded, cool position should be selected for it, such as a north border on which the sun's rays are not too powerfully felt. For Spinach good rich soil is indispensable at all times, as the quicker it grows the more succulent and delicately flavoured are the leaves. There are

many so-called substitutes for summer Spinach, but when well grown none equals the Round-seeded common summer kind. I find it best at this time of year, after sowing the seed, to give the drills a good soaking of water before covering in the seed. After that it vegetates regularly and rapidly, and is soon ready for use.—J. GROOM, *Seafield, Gosport.*

AMONGST THE CAULIFLOWERS.

ALL who can call to mind the advent of the Walcheren variety must freely admit that Cauliflowers have been greatly improved, and the gain has not been wholly in one direction, for the season of use has also been extended. The old purple and white Cape varieties that twenty-five years ago were standard kinds for autumn use are now seldom seen. They have been superseded by varieties of better quality, and which come into use at the same time.

THE WALCHEREN may be described as an early summer and late autumn kind, but it is best in summer, that is to say, when sown in early spring, it comes into use in July and August. It is, however, not always satisfactory, being liable to produce very deformed heads, but when in good form none beats it. We use it at two distinct seasons, viz., early summer and late in autumn; for the first we sow about the end of August, winter the plants in handlights or frames and plant them out in March. These come into use about the middle of June and last for a fortnight or more. For late autumn and winter use we sow about the middle of June, but are careful to give the young plants every possible chance of growing quickly. We either sow in a temporary frame or on a warm border where the seedlings come frequently under the eye, and can have the requisite attention in the way of watering. About the end of July the plants are large enough to be planted out. They are then put into ground on which early Peas grew and which is always manured in winter for the Peas. It therefore only requires forking over and the hard lumps broken to pieces to make it suitable for the Cauliflowers. Drills are then drawn 3 inches deep. We prefer planting in drills in summer, for when the plants want water it is more concentrated than when applied on a level surface. We place the plants 2 feet apart every way, and, except that they may want an occasional watering when first planted, they give no further trouble, except keeping them free from weeds. As to coming into use, a good deal depends upon the weather. In mild autumns some of them will probably be ready by the middle of October, but we never want them so early as that, as supplies at that time can be had from another variety. Our aim is to get this sowing fit for use in November and December, and it is not often that we are disappointed, but we have to watch the crop during severe frost; a few degrees does it no harm, but when the thermometer reaches 10° or 12°, heads large enough for table are not safe. On the approach of frost we go over the plantation and lift any that are ready for use, and replant them in a bed of soil in a pit or frame where they can be protected.

VEITCH'S AUTUMN GIANT is also a valuable Cauliflower. When sown in September it succeeds the Early London and Walcheren, sown at the same time, thus carrying on the supply until the early spring sowings come into use. It is also a valuable exhibition kind when the heads are obtained from September-sown plants, but with me it is useless as a summer variety when obtained from sowings made early in spring under glass. I find it comes in admirably in July from September-sown seed, and in September and October from sowings in the open ground in April. One great fault of this variety is its tendency to produce blind plants, or rather, I should say, the plants go blind after they are planted out, and the numbers that do this in dry weather is sometimes alarming. For delicacy of flavour and the whiteness of its heads it is unsurpassed.

DWARF ERFURT.—This is a summer variety of great excellence. It is dwarf and compact, and produces fair-sized heads of good colour and

flavour. If the seed is sown on a warm south border where the soil is rich any time between the 1st and 15th of April, and otherwise well cared for, it will come into use in August. Being a dwarf grower, it does not require so much room as other sorts; a distance of 20 inches apart every way is ample space for it. It is not a desirable kind to sow in the autumn to furnish a supply for early summer use, as it is rather tender.

EARLY LONDON.—In what way some of the so-called new kinds differ from this I cannot say. Having tried most of them, I must confess that I cannot see any difference. However, I have no wish to deter anyone from growing new sorts; I can, however, with confidence assert that Early London is not easily beaten. The time for sowing to furnish a supply of plants to stand through the winter under the protection of handlights or in pits or frames will vary according to the locality. In the west of England I find the first week in September to be quite early enough, but farther north probably a fortnight earlier will not be too soon. This variety is a vigorous grower, and in a good rich soil can be grown to a large size. As a summer variety, sown in April, I do not consider it equal to the Dwarf Erfurt.

STADTHOLDER.—Before Veitch's Autumn Giant was introduced this was my favourite sort for use during August and September. In order to secure a supply for the first-named month I used to sow on a gentle bottom heat early in March, and nurse on the plants in boxes until they could be planted out. From these we obtained a fine supply of magnificent heads. A second sowing should be made in the open ground about the middle of April, the produce from which will turn in for use in September. This variety is hardly so self-protecting as some; it is therefore necessary to watch the heads as they expand, or strong sunshine may discolour them. In other respects it is a very desirable kind to cultivate for late summer use. In the way of

CULTIVATION there is little more to be said. It may, however, be of some service to the inexperienced to say that the Cauliflower can only be successfully grown in a rich, deep, well-stirred soil; and it is one of those subjects that do not object to fresh manure if well incorporated with the soil.

J. C. C.

RHUBARB AND ITS CULTURE.

RHUBARB finds a place in every great garden in the country, and no matter how small the cottager's plot may be, it is sure to include one root or more of Rhubarb. Its cultural wants are few, and it is not at all liable to become diseased or injured by insects. As a rule we find it planted in out-of-the-way corners. In such positions six roots will frequently not yield so much produce as one good one would do under more favourable circumstances. Deeply dug, heavily manured soil and a shadeless position are the conditions under which the best Rhubarb is produced. The best way of propagating Rhubarb is by division of the roots, an operation which should be done before growth begins. Surface mulchings both in summer and winter with strong manure are of great assistance to Rhubarb, but all the feeding should not come from the surface, and before planting the ground should be turned up and manured thoroughly. Forced Rhubarb is most valued by many, being very tender, but it should be had equally so out of doors throughout the spring, summer, and on until September. As generally treated it becomes very tough by June, and then its use ceases; but we have had it as tender and beautiful in colour three months after the time just named as ever we were able to get it in April or May; this is done by never allowing any stems to remain on the plants after they have become too old for use. It may often happen that there is much more produce than is required at a particular time, but this should not be taken as a reason for allowing the stems to become old; on the contrary, I would advise them to be pulled off and thrown away, thereby encouraging a regular supply of young growths to be produced. By taking away the old stems, young ones will continue

to come to the very end of the season, and with plenty of feeding, I have proved that their removal will not injure the plant more than does taking them off in spring. A dozen of our plants treated in this way last autumn have been furnishing us with many good gatherings lately, and they will be subjected to the same treatment again. All who wish to grow Rhubarb for exhibition should adopt this plan, especially for autumn shows, as the stalks will then be spring-like as regards tenderness and purity of colour. I have sometimes pulled away every stem visible from our Rhubarb in July, the result being that in August and September we had a young crop, the growth of which was admired both in the garden and on the table. Where roots are wanted for forcing from Christmas onwards a few of them may be allowed to mature their growths as early in the season as possible, but where nothing of this kind has to be provided for I would always encourage them to throw up young growths until September.

CAMBRIAN.

MAGNUM BONUM POTATO.

I AM afraid that this well-known variety of Potato will in this district, at least, be shortly numbered among the "cast-offs." Last season it grew weakly with us and our neighbours, not requiring nearly so much space as was given the sets, and this want of vigour, as might be expected, resulted in a light and, for the variety, a much diseased crop. This season I procured a change of seed from a considerable distance in the hope that our old favourite would again prove profitable, but, judging from present appearance, it will not be so. Scotch Champion, Reading Hero, Regents, and Schoolmaster are all growing splendidly, but the Magnums are anything but vigorous. What is the matter? Has the variety so quickly become worn out? I used to think, though I suppose erroneously, that one of the American varieties, partly, and it may be accidentally, originated Magnum Bonum, but then these are most profitable during a dry season. Nothing could look better than the American varieties do this season; even the old Early Rose, which some of the cottagers still stick to, has made exceptionally rapid and strong growth. The soil in the district is heavy and not well suited to Potatoes, but it seems strange that this apparently most vigorous of growers should be the first to collapse in an unfavourable season. Perhaps my experience is singular. I hope it is, but at any rate unless Magnum Bonum rapidly improves it will next season be wholly instead of, as now, partially replaced by Reading Hero.—GROWER AND EXHIBITOR.

White-seeded Kidney Bean.—As a late Bean this is superior to the Scarlet Runner, although in most respects, except in the colour of the seed and the flowers, it somewhat resembles it. I have planted it as late as the middle of June with good results, but as a rule the first week in June is quite late enough to plant runner Beans of any kind. It often happens that those Beans which are sown early and which have to bear the heat of July get exhausted before autumn, and then late-sown crops become exceedingly useful, as in every garden there should be plenty of Kidney Beans till cut off by frost. The main and also the late crops of Kidney Beans should be planted on good land; the rows should be at least 6 feet apart, and even if wider they will succeed all the better; indeed, all tall crops such as Kidney Beans and Marrow Peas are best isolated with dwarf crops between the rows, and the further the latter are off each other the better, as plants that have plenty of light and air make more sturdy growth and larger, better built-up foliage, and feel to a less extent the vicissitudes of climate to which we are so much exposed than those closer planted. Mulching, if only short Grass from the lawn, should be attended to as soon as the weather becomes hot and dry and the plants appear distressed; in fact, we ought not to wait for the plants to become distressed with heat and drought before we help them in this respect.—E. H.

Cauliflowers and maggots.—I have heard a good many complaints this spring about maggots making sad havoc among early Cauliflowers. The first symptoms of their presence is the wilting of the leaves, and in the course of a few days the plant dies. The maggot, a small, white hard-skinned larva, perforates the stem underground. Sometimes several are found in the stem of one plant, and they are generally more troublesome in dry seasons than in wet ones. They also attack Brussels Sprouts and other members of the Brassica family at this season. Fresh lime and soot are very useful both as preventives and also for their destruction. In transplanting Cauliflowers or Broccoli, if any doubt exists as to the condition of the plants, dress their roots with the following mixture: To 6 oz. of soft soap add two wineglassfuls of paraffin oil, and blend the two well together; then mix with two gallons of soft water. When this has been well stirred, thicken it to a puddle with lime and soot, and dip the roots and stems in just before planting. Any less quantity may be made in the same proportions. Any plants too large to be so treated, water with soot and lime water, or strew soot and lime round their stems and water them in.—E. HOBDAY.

Johnstone's St. Martin's Rhubarb.—Messrs. Laird & Sinclair seem to be displeased because I recently published in THE GARDEN the conclusions resulting from a trial of Rhubarbs at Chiswick, sample bundles of which were shown at South Kensington for the inspection of the fruit committee. Looking over these, I noted Johnstone's St. Martin's with both the Linnaeus group and the Early Red or popular London market kind, the names of the respective firms who had sent these kinds to Chiswick being given on the labels. To those I made no reference, but it was particularly unfortunate that this so-called new Rhubarb should have been in two distinct forms, inasmuch as it was not possible to say which was the true sort. If the kind is either one or the other, it is not new. If it is neither, then it would seem that the true sort cannot be at Chiswick, and Messrs. Laird and Sinclair will do well to send roots of the true kind there as soon as possible. No doubt the kind in question is a seedling, but Rhubarbs are seldom cross-fertilised, and as a rule reproduce themselves, yielding nothing new. In any case, if Messrs. Laird and Sinclair are dissatisfied with the Chiswick representatives of their Rhubarb, they can soon remedy the defect.—A. D.

—This has long been a favourite with me, but it is probable that inferior varieties are sometimes substituted for it. The description given of it (p. 527) agrees with my experience as regards the variety which I grew as the true St. Martin's. It was excellent in colour, and produced an early crop of medium sized stalks which were very tender and juicy; in fact, we always relied on it for the earliest and latest supply, as in addition to forcing readily, it was naturally at least ten days earlier than the larger coarse growing kinds like Victoria, and for this reason it was usually pulled very hard at first. It was then allowed to grow unmolested until the end of the season, when it again came into request, as the stalks of this kind were tender and juicy when other sorts were hard and stringy. I consider it to be one of the very best varieties to grow for private use. Market growers of course want size, but anyone requiring a few roots for their own use should most assuredly select a variety that produces a quantity of medium sized stalks such as this does. As regards growing Rhubarb, a good kitchen gardener has said, "Always select a site near the manure heap, and do not forget to apply it liberally at the winter dressing."—JAMES GROOM, Gosport.

—Would Mr. W. W. Johnstone add to our indebtedness to him for telling us the origin of St. Martin's Rhubarb by giving a description of the true variety, in order to satisfy growers of it that they have the real sort? This is necessary, seeing that it is known that there is much being grown that is not true.—AN OLD RHUBARB GROWER.

Early Peas.—Until this season I always had an idea that William I. was at least as hardy as Ringleader, and perhaps one ought not to draw conclusions from so exceptional a season as the

present one has been. I sowed Ringleader and William I. on a south border on the 11th of last November under exactly similar conditions. Both appeared to do equally well until the March winds blew through them; and now whilst the Ringleader rows are quite full, those in which William I. grows are very thin. However, there is no question that the latter is about three days the earlier. This has been a bad season for autumn-sown Peas, and very little has been gained in point of earliness. We gathered our first dish of autumn-sown William I. on June 13. Autumn-sown Ringleader are now (June 16) just about fit to pick—I mean, of course, the most forward pods. William I., sown on February 26, is also in just about the same condition, and there is not more than a day or two difference between the latter and Kentish Invicta, sown on the same date. Emerald Gem, sown about the middle of March, is running them close, only a few days separating them. The autumn-sown crops have the shelter and warmth reflected from a south wall, whilst the February sowings are growing in rows running north and south across the open quarter. Taking the average of seasons, I find that Peas sown about the third week in February are nearly as early as those sown in autumn, and they are usually more prolific.—E. HOBDAY.

GARDENS AND PARKS ABOUT DUBLIN.

TO THE EDITOR OF THE GARDEN.

SIR,—Permit me to say a few words on this subject, the result of a recent visit to Dublin. Trees and shrub vegetation seem fresher and healthier in that city than in any large town with which I am acquainted. Pink and white Hawthorns and Laburnums look invitingly over the railings in the squares. In the neighbourhood of Trinity College Garden the roads are lined with stately trees, and the garden itself is most interesting. Unlike that at Edinburgh, one does not enter it through a hole in the wall; on the contrary, it is enclosed by fine iron railings, over which Laburnums hang their golden tresses, and through which may be seen under their shade and that of other trees Daffodils, Bluebells, Foxgloves, and other under-wood plants. Inside there is a feeling of quietude which is most delightful, and which one would scarcely expect in a garden wholly surrounded by buildings. Its trees, the growth of some eighty years, are in many cases large and healthy, especially some of the Cratæguses, Pyruses, Beeches—purple, Fern-leaved, and others, Elms, weeping and otherwise, and Hollies of different kinds, for which this garden is celebrated. Of Hodgins's Holly and Ilex balearica, two kinds a good deal alike, there are some fine specimens; but, singular to say, while the former is clean and healthy, balearica is, in all cases, infested with that Holly pest called *Phytomyza aquifolia*, a leaf miner, which causes the foliage to blister, then turn yellow, and eventually to wither and drop off. Last winter, though merciful to Londoners, was a hard one in Dublin. Euonymuses were killed outright—a fatality which even Mr. Bain, so long curator of this garden, never remembers to have happened before. On walls various shrubs, such as *Berberis nepalensis*, *Magnolias*, *Benthamias*, *Ceanothuses*, *Smilaxes*, *Edwardsia microphylla*, and the *Paulownia*, have suffered severely—not wholly, perhaps, from the effects of last winter, but also from those of its predecessors. Wholly untouched by frost is the Tennessee Yellow-wood (*Virgilia lutea*), here a tree 20 feet high, or the *Weigela*, a bush on the open lawn. 8 feet by 12 feet, spreading and weeping—a good illustration of what shrubs become when freed from crowded shrubberies. On the wall the Potato Tree (*Solanum crispum*) was beautifully in bloom; also *Akebia quinata*—quite a hardy plant here. *Pittosporum undulatum*, too, has stood the winter well, and so has *Garrya elliptica*, a bush, or rather tree, between 15 feet and 20 feet in height.

The different borders are as full of plants as they well can be, Mr. Burbidge having added largely to them since this garden came under his care. Of Daffodils and Christmas Roses he has

unique collections, as well as of Irises, Lilies, and Primroses, some of the last, as, for example, varieties of the Japanese kind, being even now in bloom in a shady nook. The three varieties of *Eulalia*, striped, barred, and green, are also here, as are likewise various crown, alpine, and other Anemones. *Spiraea Aruncus astilboides* reaches a height of 6 feet or 7 feet, and when in bloom is as handsome as any of the genus. Of Siebold's Plantain Lily I observed some grand clumps, and also a plant or two in bloom of *Meconopsis nepalensis*, a handsome Himalayan Poppy, very peculiar in colour, owing to the yellow aspect which the whole plant presents. Squills of different kinds grow and bloom well partially shaded by trees, especially those belonging to the campanulata section, and the same remark applies to Plantain Lilies, Pæonies, and the common London Pride, with which a shady walk is thickly edged. The Satin-leaf (*Heuchera Richardsonii*) forms a good hardy border plant, and in a cut state is excellent for indoor decoration, lasting long in water; under sunshine its colours are most beautiful, and they are scarcely less so under artificial light. *Ourisia coccinea*, quite hardy everywhere, promises to be a valuable plant, as are also *Camasia esculenta* and its white variety. The botanical arrangement, beginning, as is usual, with Ranunculaceæ, and ending with Ferns and other Cryptogams, contains some 2000 species planted in beds separated by 4 feet wide Grass walks, and every plant is well and conspicuously labelled, which it should be where, as here, the collection is kept in a 'quarter by itself wholly for educational purposes. Other parts of the garden are less formal; here a bit of rockery planted with *Aubrietias*, *Saxifrages*, *Iberises*, dwarf mule Pinks, *Alyssums*, the white *Phlox Nelsoni*, and similar plants, and crowned with *Cotoneasters*; there a bit of wall garden on which are the white *Toadflax*, the *Edelweiss*, the pretty little purple-flowered *Erinus alpinus*, *Stonecrops*, and some of the dwarf *Speedwells*. In another step or two one comes upon a pond filled with aquatics and edged with *Kämpfer's Iris*, which seems to like the moisture here afforded it, for it is growing with unwonted vigour. These, the well stocked glasshouses with Orchids, stove, and other plants, the fine collection of hardy flowering plants, and the rich tree and shrub vegetation, make this a garden of which Mr. Burbidge may well be proud.

PHENIX PARK, one of the loveliest of public parks, contains 1760 acres, boldly and charmingly undulated, and embellished by two noble pieces of ornamental water. There are 500 acres in the drill-ground alone, and thirteen in what is called the people's park, on the higher ground of which is some rock garden planted with *Aubrietias*, *Iberises*, *Alyssums*, and similar plants. The boundary fence is said to be seven miles round, and the park is bisected by a straight road three miles in length. Noble old Hawthorns, in many cases grey with Lichens belonging to the genera *Ramalina* and *Evernea*, are spread over hundreds of acres; in short, the park looks as if at one time it had been a Hawthorn forest, and just now when in bloom they have a wonderfully fine effect. Many of them are of large size, one being 8 feet in circumference. But there are other fine trees in this park. Two Poplars measured 10 feet 8 inches in circumference, an Elm was 11 feet 7 inches, two Oaks 14 feet 6 inches, another 13 feet, with a bole 20 feet high without a branch, a fine clean bit of timber; a Larch measured 7 feet 9 inches, a Cherry tree 8 feet, a Beech 9 feet, a Sycamore 9 feet, and a Chestnut 10 feet, measurements all taken at 4 four feet from the ground. About the Vice-regal Lodge there are also some fine trees, especially a purple Beech, very old and of large dimensions, and in the grounds attached to the superintendent's (Mr. Dick's) residence there are some large *Welling-tonias* and other Conifers, especially a fine *Cupressus Lambertiana*, a species which was killed in most places by the severe winter of 1878. Irish Yews thrive, as they should do, well here, most of them being unusually large and spreading. Of *Thuopsis dolobrata* and *Libocedrus decurrens* there are also noble examples. In short, all the best hardy Conifers are well represented in this enclosure,

in which there are numbers of glass houses, and a nursery for supplying the park and public gardens with young trees. Fruit trees on a wall here were carrying good crops, especially one—an Apricot—on a portion of wall which was heated. This, Mr. Dick informed me, invariably bore good fruit, even in seasons in which other trees on the same wall were fruitless, a strong argument in favour of heated walls. Dying off of the branches, too, so common in Apricots, is likewise unknown in the case of this tree. Altogether everyone must be pleased with Phoenix Park with its broad acres of Grass, its miles of well-kept roads, its ornamental water, its Thorns and other trees, and last, but not least, its hill and dale.

GLASNEVIN was next visited, a charming garden, long under the curatorship of Dr. Moore and now ably conducted by his son, who is extending and improving it in the true sense of the word. A large piece of new ground has lately been added to the arboretum, and the valley through which the Tolka slowly meanders is henceforth to be rendered more attractive by being relieved of its overcrowded timber, by forming better pathways and by sowing broadcast wild flowers along the river banks and on the surrounding slopes. Higher up this glen one crosses a sinuous piece of water filled with Water Lilies and other aquatics, then recrossing it and passing Addison's Walk over-canopied with Yews on the rising ground the hill-top is reached, where there is a walled-in reserve garden in which are some fine plants. Here, as well as in Trinity College Gardens, we found *Veronica Hulkeana* flowering beautifully, a really good plant and hardy, at least against a wall. Here, too, was a fine collection of single *Pæonies*, *Saxifraga Wallacei* in all positions a bright and showy plant, *Meconopsis Wallichii* and *nepalensis*, the white *Ranunculus parnassifolius*, and the blue *Mertensia paniculata*. The great Mullein (*Verbascum Thapsus*) I also noticed here; boiled in new milk, it has the reputation of being a cure for consumption and other chest diseases, and for such purposes, Mr. Moore informed me, there is a great demand for it. The glass-houses are large and spacious buildings, especially good being what is called the curvilinear range. In the Victoria house is a grand collection of *Sarracenias*, some of them hybrids raised by Mr. Moore; conspicuous amongst them were *Chelsoni*, a fine kind with handsome red pitchers; *Drummondii alba*, *Williamsi*, and *flavamaxima*. The interior of the house is much like that at Kew; in the centre is the Royal Water Lily, and in the little tanks at the corners are blue and red flowering *Nymphaeas* and other interesting plants. In the New Holland house the variegated *Phormium Cookii* was in flower, a stately plant with leaves 9 feet high and 8 inches broad, cream striped and very beautiful, quite different from the ordinary split-leaved variegated kind. In the Palm house were some noble specimens, and in one of the stoves, *Brownea Ariza*, from New Granada, was in flower, each cluster of blossoms being bright crimson-scarlet, and as large as the largest double *Pæony* I have ever seen. *B. grandiceps*, another fine species, has also flowered in this garden. Alluding to *Pæonies*, I may just mention that the Moutans on the lawn have been badly injured by the winter. *Crinums*, once considered to be hothouse plants, are grown out-of-doors here planted close to the walls of the houses, and treated just as one would *Belladonna Lilies*. On *C. latifolium* fourteen flowers were counted in one head, and *Mooreanum*, amiable, and others were equally floriferous. All they need is deep planting and a covering of leaf-mould or ashes in winter when the tops have died down. One of the most interesting houses at Glasnevin is the Filmy Fern house. Nowhere else have we seen such vigorous specimens, and nowhere else are these plants treated in such a simple manner. No bell-glasses cover even the finest species, and in the coldest winters no heat is ever given, yet the plants look healthy, and are unusually large and fine, some of the *Todeas* measuring quite 5 feet through, the dense feathery fronds arching on all sides down to the stage in a most graceful manner. Such a house as this anyone might possess,

All that is wanted is a north wall against which to build it and a shaded roof. At one time it was thought these Filmy Ferns must be kept closer than other Ferns, and therefore those on the back stage were cased in with glass. This Mr. Moore has partly taken down; and finding that its removal inflicted no injury on the plants, he intends soon to take it wholly away. All they want is to be kept damp and shaded, and they will not fail to thrive.

In the Orchid houses many sorts of *Masdevallias* were in flower, such as *M. rosea*, *Backhousiana*, *Rozlii*, *igneae*, *Sanderiana*, and other rare kinds. In the case of warm houses in which large plants are kept in pots or tubs, such as *Palms* and tropical Ferns, Mr. Moore is in favour of a floor made of ashes which, when kept damp, supplies the atmosphere with moisture and maintains it in a much more genial state than a floor made of flagstones would do.

In order to show the interest taken by the public in this really fine botanic garden, I was informed that some 40,000 persons visited it in May, a large number considering that the population of Dublin is only 235,000.

A new public park has been formed at Blackrock, and starting from this up Merrion Avenue, Mount Merrion, one of the seats of the Earl of Pembroke, is reached, a charming place for many years under the care of Mr. Welsh. There is here a good kitchen garden, a noble park, and fine pleasure grounds, which, lying high above the sea, overlook the bay at the mouth of the Liffey, bounded on one side by the "wind-swept" hill of Howth, and on the other by the Dublin mountains, even the distant Sugar-loaf coming into view, a panorama comparable only with that seen from Arthur's Seat at Edinburgh. Being associated with so much natural beauty, no paltry bedding is attempted at Mount Merrion; no rockery, except a few Moss-clad boulders cropping out of the turf, finds a place there. On the contrary, its chief features are its woods, traversed by well-kept walks, its ample lawn, and the noble avenue through which it is approached. There is also a large and well stocked kitchen and fruit garden, and several houses of well-grown Orchids, Ferns, and fine-leaved tropical plants. J. M.

FERNS.

BEST CULTIVATED FERNS.

(Continued from p. 534.)

DOODIA.—Although not an extensive genus, this is one very rich in decorative Ferns of small habit, as, with the exception of *D. blechnoides*, all the species and varieties which it contains are of dwarf growth, but nevertheless they are found very useful, especially for Fern cases, for edging of window boxes filled with taller growing kinds, as one often sees now in London houses on north and north-east aspects, where they replace with advantage flowering plants which cannot be expected to prosper under such conditions. Although some of them grow more luxuriantly in stove temperature, and produce more massive foliage under such treatment, none of them positively requires great heat; the cool or the intermediate houses are the places suitable to all of them. They are equally valuable for mixing with cut flowers, as in that state they keep fresh for a considerable time. Again, they are very useful for forming an undergrowth in cool houses devoted to Orchids, &c., the more so that they are a class of very clean plants, being seldom infested with any insect, and they bear fumigating without receiving any injuries therefrom. As they are of very accommodating habit if planted under or grown amongst other plants, they will bear with impunity syringings that may be found necessary to the welfare of the other plants, or do equally well without, as the case may be. They should be potted in a compost of three-parts of peat and one of silver sand. I have never seen them derive any benefit from loam being added to the compost; indeed, I think it prevents the fronds attaining their full development, and

have always noticed that a light soil suits them much better. The drainage of the pots must not be overlooked, as they are very sensitive to the effects of stagnant water.

D. ASPERA.—A very fine Australian species, of erect, bold-growing habit, and very dark green in colour. The fronds, which are produced in great abundance, are very harsh and rigid; they are lanceolate in shape and pinnatifid, broadest in the centre, and average from 8 inches to 10 inches in length. In a young state, and until they are quite developed, they are of a very beautiful purplish metallic hue, which gradually turns to the darkest green. Greenhouse.

D. ASPERA CORYMBIFERA AND MULTIFIDA are two very pretty and interesting garden varieties, both differing widely from the typical plant, and yet being totally distinct from one another; they are both of dwarf and of more compact growth than the species from which they spring. The variety *corymbifera* is of stiff, erect habit, and has its fronds densely crested at their extremity, resembling in that respect some of the many interesting forms of our native *Athyrium Filix-femina*. In the variety *multifida* the fronds are longer, and, instead of being of erect habit, as in the preceding variety, are drooping and forked at their extremity instead of being densely crested; it is also of a much better habit, as it produces fronds in great quantities, whereas the variety *corymbifera*, although very pretty, is not at all liberal in the production of its tufted fronds. The young foliage in both varieties is of a beautiful coppery tint, changing to dark green with age. Greenhouse.

D. BLECHNOIDES.—This handsome Australian species is the largest or tallest growing of the whole genus in cultivation; its highly decorative pinnatifid fronds grow from 12 inches to 15 inches high. They are produced from an upright short stem, and are broadly lanceolate and rigid, of a dark green colour, with pinnae broadly ciliated on the edges. Greenhouse.

D. CAUDATA.—This, although the commonest kind, is one of the most useful of all *Doodias*; it is the best for growing in Fern cases, and also for growing under plants of any sort where a green background is requisite. It is also very useful for planting on the wall or in any crevice of the rock fernery, where it displays its pretty wavy foliage to great advantage. The fronds, which are produced very freely from a central crown, are from 5 inches to 9 inches in length. It also differs from the other species belonging to the same genus in bearing two distinct sorts of fronds; the sterile are pinnate, with oblong pinnae, flat, somewhat undulated, and closely set together, whereas the fertile ones, although pinnate also, are totally different, for they have contracted pinnae set rather far apart. The barren fronds are drooping, whereas the fertile ones are rigid and stand erect about 6 inches or 7 inches high; the pinnae of both are slightly cordate at the base, and both fronds are terminated by a tail-like process, often measuring 2 inches long. Native of Australia. Greenhouse.

D. CAUDATA LINEARIS (confluens).—A New Caledonian variety which somewhat resembles the preceding species, from which it seems to issue, especially as regards the barren fronds, which are very similar in appearance, but the fertile ones are less divided; they both rise from an erect caudex, and grow to about 8 inches long, the barren pinnatifid below, the fertile confluent, so as to become linear; these are much contracted. It is most useful for small Fern cases. Greenhouse.

D. DIVES.—A very handsome and most distinct species from Java, and the only one in the whole genus which requires stove temperature. The fronds are produced sparingly when compared with the other species; they grow to about 15 inches high, and are of a dark green colour and pinnate; the lower pinnae, about 2 inches long, are stipitate and auriculate on both margins; the upper ones are differently placed—they are sessile and much shorter; the stalks are black and rather scaly. It is particularly remarkable for its prominent and large sori.

D. MEDIA (lunulata).—A very pretty New Zealand species; indeed, it is perhaps the most charming of the genus. It is of a more slender and pendulous habit than any of the others. When young the fronds, which grow from 10 inches to 18 inches long, are of a light red tint, changing with age first to a metallic colour, then to a dark green; they are lanceolate in form, pinnate, and the margins of the obtuse pinnæ are spiny-toothed throughout. It is most elegant, and its fronds are very useful for cutting. Greenhouse.

TELLEA.

ORCHIDS.

Cattleya guttata.—Of this superb Orchid Messrs. Thomson & Sons, Clovenfords, Galashiels, send us a wonderfully fine variety remarkable for the unusually rich colour of the lowermost lobe of the labellum, which is a brilliant magenta. In contrast with this is the pale mauve colour of the unfolding wings of the lip, while the thick wax-like sepals and petals are pale purple copiously freckled and blotched with carmine. It is one of the finest varieties we have seen, and quite distinct.

Saccolabium guttatum.—Rarely have we seen such a fine spike of this lovely East Indian Orchid as that which has been sent to us by Sir Alexander Ramsay from Cheltenham. It measures 21 inches, and of that length 18 inches are densely covered with blossoms, which seem to be more profusely spotted than ordinary. A superb wreath such as this indicates skilful culture, and this is corroborated by a similarly fine spike of a splendid variety of *Cattleya Mossie* from the same garden, and which carries four finely developed flowers on one spike.

Epidendrum nemorale is, in our opinion, one of the gems of the genus, for it combines such elegant growth with such beautiful flowers. The latter measure some 2 inches or more across, and are of a delicate rosy pink, the broad labellum being exquisitely veined and pencilled with a deeper tint. The flowers are produced in clusters on tall slender stems springing from plump egg-shaped bulbs. It is an indispensable plant for growing in an intermediate house. There is now a fine example of it in bloom in Messrs. Shuttleworth & Carder's nursery, Clapham.

Lælia purpurata.—A variety of this *Lælia* noticed in a late number of THE GARDEN is described as having mauve-purple petals and sepals and a deep port wine coloured lip. I fancy most of the later importations of this species approach this description nearer than the original, and, as many think, better form with white petals and sepals and a rich crimson-purple lip. We have a number of plants of the dark kind, from some of which we have lately cut spikes with five large flowers on each, but they were all recently established imported plants when we got them. A small plant which I got at Dr. Paterson's sale at Edinburgh, and just now unfolding its buds, three on a spike, promises to be more like the old variety, as I knew it about twenty years ago. These dark kinds have no purple in their composition, and should be known by another name. The original and typical form was white with a purple lip, and at a distance looked more like a white-petalled *Cattleya Mendelli* than the present dark-flowered *Lælia purpurata*.—J. S. W.

SHORT NOTES.—ORCHIDS.

Palumbina candida is a pretty white Orchid, reminding one of *Odontoglossum pulchellum*, but the flowers are less wax-like and the labellum unusually long and oval in shape. It is grown with the cool Orchids at Kew, where it is now in bloom.

Oncidium cucullatum Chestertonii.—This is a distinct variety and a very pretty one. It resembles the type and other varieties, with the exception of the colour of the flowers. The sepals and petals are a deep vinous-purple, almost a port wine tint, while the ample labellum is white, copiously freckled and spotted with rich carmine. It may now be seen in flower at Kew.

Broughtonia sanguinea.—By far the most remarkable of all the Orchids now in flower at Kew is an exceptionally fine specimen of this Jamaica species; it is attached to a suspended block, and is carrying about half-a-dozen slender spikes some 18 inches in length, each borne horizontally and terminated by a cluster of purplish crimson blossoms, which are exceedingly beautiful, the admiration of every visitor. As this is one of those Orchids seldom seen in a flourishing, much more in a flowering, state, it would be interesting to know the particular line of treatment accorded it at Kew.

The Dove Plant (*Peristeria elata*) is not so often met with in flower as one might suppose, and we have seen it nowhere this season, except in Mr. Soper's garden at 307, Clapham Road, where there is an uncommonly fine specimen now carrying a tall, stout spike of large, white, wax-like blossoms, the interior part of which so much resembles a bird. Mr. Soper is particularly successful in cultivating this Orchid, for it seldom fails to produce an annual crop of blossoms. He grows it in a moderately warm and moist house, and gives it much the same treatment as *Phaius* and other strong-growing terrestrial Orchids. One great point seems to be in not over-potting the plant or frequently shifting it from one pot to another. It is one of those Orchids which are best left alone for years if doing well.

Vanda Hookeri at Tring Park.—The treatment recommended by Mr. Hill last season has once more proved to be correct. At Tring Park there are now several plants of this *Vanda* in bloom, and of ten plants purchased last year no fewer than nine have flowers or buds on them. The result then is that *Vanda Hookeri*, under proper treatment, will flower as freely as an *Odontoglossum*, and so bids fair to become a plant for every collection. There seems to be two forms of it; one, with smaller, far less finely coloured flowers, and a thick stem almost of the size of *Vanda teres*, comes from Cochín China, and is far inferior to the thin stemmed, and finely coloured form from Borneo. A specially fine variety is now in bloom at Tring Park; the heavily spotted and deeply coloured lip is nearly 2½ inches across. A more beautiful Orchid than *Vanda Hookeri* cannot easily be imagined.

Masdevallias form now one of the chief attractions in Messrs. Shuttleworth & Carder's nursery in the Park Road, Clapham, and the collection includes some rarities as well as those of the ordinary class. Among the former is the new *M. cucullata*, to which allusion was made a short time since; *M. trochilus*, the Humming Bird Orchid; *M. Shuttleworthii*, and the singular *M. Chimæra*. Among the plants of the latter there is a variety remarkable for the chocolate tint of the slipper-like labellum, whereas in typical *M. Chimæra* it is white. The sepals, moreover, have a darker ground; in short, it is a most distinct and handsome variety. It is not yet named. Among the varieties of *M. Lindenii* is one remarkable for its unusual dwarfness, the whole sheaf of blossoms being not more than 9 inches or so in height. The plant is altogether a compact grower, an abundant flowerer, and brilliant in colour. The varieties of *Harryana* also comprise some very choice ones, the pick of the large importations which are made of these *Masdevallias* by this firm.

Vanda teres.—Having frequently to reply to the question, "How am I to grow *Vanda teres* in order to get it to bloom?" I have thought that a note respecting a plant of it which I saw the other day might interest those of your readers who are anxious to succeed with this truly lovely Orchid. At Mr. Druce's, Dulwich, there is now in bloom what might be termed a small plant of this *Vanda* with three spikes carrying twenty-one of its beautiful flowers, seven on each spike. The plant is about 3 feet above the piece of cork to which it is attached. On enquiry, Mr. Bachelor, the successful grower of it, informed me that it was never out of the stove, in the centre of which is an open water tank, but during the winter months it is hung up near the glass where there is always a genial moist heat. It seems, therefore,

unnecessary to nearly kill the plant with drying, which is often done in order to make it bloom. It is marvellously beautiful when flowered as this little plant now is.—HENRY JAMES, *Lower Norwood*.

INDOOR GARDEN.

LILIUM DAVURICUM IN POTS.

AMONG the most satisfactory Lilies for pot culture—that is to say, those from which a good show of bloom may be confidently expected even under very simple conditions—are the different varieties of *L. davuricum* or *umbellatum*, now grown largely by the Dutch, and imported in quantity during the winter months. They are cheap compared with most of the others, and are well worth attention where a supply of flowering plants has to be kept up. All that is necessary is to pot them as early as possible, and place them in a sheltered spot out-of-doors. In the event of sharp frost occurring they may be either covered with coal ashes or litter to prevent the soil from freezing too hard, but the covering must be removed before they start into growth in spring. They may be allowed to stand in the open ground till the blossoms are on the point of expanding, when they should be moved into the greenhouse, conservatory, or wherever required. If potted singly, 5-inch or 6-inch pots will be large enough, but they may be potted so as to form a mass. A good way is to put three bulbs triangularly in a 6-inch or 7-inch pot. In mentioning the size of the pot I refer to such bulbs as are commonly imported, as occasionally very large specimens are obtained, which will, of course, need a correspondingly larger pot. The bright orange-red or crimson flowers of these Lilies are very showy when used in conjunction with other subjects. *L. davuricum* will grow and flower well in the open border, to which the pot plants may be advantageously transferred after blooming under glass, and allowed to remain for two or three years before being again disturbed. Some of the best Lilies for this purpose are *maculatum*, spotted, orange-red; *marmoratum*, orange marbled with crimson; *Sappho*, very bright and deep orange; *erectum*, orange; and *incomparabile*, rich, glowing crimson, the most conspicuous of the whole, and one of the cheapest. By slightly protecting some they may be had in bloom by the middle of May, and, on the other hand, may be retarded till the end of June.

H. P.

RHODANTHE MANGLESLI.

THIS is deservedly a great favourite with everyone, its pretty rose-coloured blossoms being equally attractive in the bud state and when expanded. The white-flowered variety of it, too, is a charming plant. At one time these *Rhodanthes* were regarded as very difficult to cultivate, but of late years they have been brought into Covent Garden Market largely during the summer, and, in common with most things grown in quantity, many of them are excellent examples of good cultivation. Quite a sheaf of stems rises from the pot, all clothed with leaves that look as if mildew, once a great pest, was now unknown. The upper portions of the plants are masses of flowers, some expanded and more in the bud state, which with attention will continue to open for a long time. The flowers of this *Everlasting* are easily dried, and in that state preserve their beauty for a great length of time. Having been very successful in the culture of this plant, I am induced to give my mode of proceeding. The seeds are sown about the end of February in shallow boxes and placed in a gentle heat, when they quickly germinate, and soon after are removed to a frame, through which a single hot-water pipe runs—just sufficient to keep out the frost. Air is given freely, and when the first leaf is developed the young plants are pricked off at once into their flowering pots. Therefore better soil is required than if they were to be again potted off. Five-inch pots are a good size for them, and these I fill with a compost, consisting of two-thirds loam and one of decayed manure, adding a little leaf-

mould and sand to lighten it if necessary, but that will depend upon the consistency of the loam. The soil is pressed moderately firm, and about fifteen young plants are dibbled in at about equal distances from each other; a dozen is sufficient, but by putting in this number a few deaths are thus allowed for. The plants are set on a well-drained ash bed not far from the glass and have all the light and air possible in order to encourage a short and sturdy growth, so that by the middle of May the blossoms commence to open and the plants are soon in full flower. Rhodanthes require careful watering, and especially avoid wetting the foliage as they approach maturity; when young, it does no harm. A little weak manure water may be given with advantage as the pots become full of roots. By varying the time of sowing a succession may be kept up, and if sown in the open ground early in May a good supply of cut flowers will be obtained at a time when they are very acceptable. A double-flowered variety was sent out some six or seven years ago, but its blooms were wanting in elegance, and it seems to have almost, if not quite, dropped out of cultivation. H. P.

Fungi in propagating pits.—I send you some specimens of a fungus with which I have been much troubled in a small propagating pit in which I have Cocoa fibre and sand for the purpose of plunging pots of cuttings, seeds, &c. The fungus is most prolific, and the powder on it, which has apparently a power of self-distribution, spreads all over the place in which it is enclosed, and every grain seems to make a plant. The growth is very rapid, and I have little doubt that if undisturbed it would grow to a large size. You will observe what a brilliant yellow colour it has. Perhaps you may be able to tell us something about it. I have often seen it stated in THE GARDEN that Cocoa-nut fibre breeds a fungus, but though I have used it largely, I have never known it to do so except in this instance.—W. J. T.

* * The name of the fungus is *Agaricus ceprestipes* so named because the stem resembles a Scallion in shape. It is of exotic origin, and often a great nuisance in frames, pits, greenhouses, and stoves; sometimes, but rarely, it appears in gardens. No doubt your fibre is completely saturated with the spawn or mycelium; the growth of the fungus being so profuse, it may speedily exhaust itself. Your observation about the yellow meal spreading from the top of the fungus is curious.—W. G. S.

Torenia Bailloni and Fournieri.—During summer the different kinds of *Torenia* form handsome plants for indoor decoration, more especially when grown in suspended pots, for which their procumbent habit eminently fits them. Two very distinct and beautiful kinds are *T. Bailloni* and *Fournieri*, the first yellow with purplish tube; the other light blue shaded with deeper blue and furnished with yellow markings in the centre. For summer blooming sow a pinch of seed about the middle of February, and as it is very minute, a pane of glass placed over the pot will be sufficient covering. The soil used should be moderately light, and as soon as sown place the pots in the stove till germination takes place, when the glass must be removed, the seedlings kept near the light, and when large enough to handle pricked off. All that is now required will be to pot off when necessary, using a compost consisting of equal parts loam and leaf-mould, with a little sand and decayed manure. As soon as established they should be transferred to a somewhat lower temperature than that of a stove (that of an intermediate house is the most suitable), and shifted into 4-inch, 5-inch, or 6-inch pots, according to the size required. They may be grown larger still, but the plants in comparatively small pots are generally the most satisfactory. These *Torenia*s require to be kept near the glass, when about June the whole plant will be a mass of buds, and will continue flowering till autumn if the seed-pods are picked off, for they produce seeds in such quantity that if all were allowed to remain the plant would die of exhaustion. Throughout the summer these *Torenia*s do well in a greenhouse or

frame, for though they will flower out of doors, bad weather plays such havoc with the blossoms that they are unsatisfactory. When once a plant of each kind is obtained a stock may be easily kept up, as the seed which is so freely produced germinates readily, and plants raised annually succeed best.—H. P.

NOTES OF THE WEEK.

APPOINTMENTS FOR THE WEEK.

- June 26.—South Kensington: Meeting of Fruit and Floral Committees of Royal Horticultural Society; and Pelargonium Society's Annual Show.
- 27.—Croydon Summer Show.
Cardiff Rose Show
- 28.—Regent's Park Evening Fête of Royal Botanic Society.
Southampton: Show of National Rose Society Richmond (Surrey) Annual Show.
- 29.—Canterbury Rose Show.
- 30.—Reigate Rose Show.
Bromley Annual Show.

NEW BRAZILIAN BEGONIA.—At the last meeting at South Kensington M. Pynaert-Van Geert exhibited from his nursery at Ghent a handsome unnamed species of *Begonia* from Brazil. It was remarkable for its fine foliage, which was large, less peltate in form than usual, and of a bronzy green, the satiny surface being prettily studded with white blotches.

THE SOCIETY OF ARTS' ALBERT MEDAL for "distinguished merit for promoting arts, manufactures, or commerce" has been awarded for the present year to Sir J. D. Hooker for the eminent services which, as a botanist and scientific traveller, and as director of the National Botanical Department, he has rendered to the arts, manufacture, and commerce by promoting an accurate knowledge of the floras and economic vegetable products of the several colonies and dependencies of the empire.

THE ASPARAGUS COMPETITION at the Colchester show last week was a good one. Mr. Harwood, who had secured the champion prize in London for 300 heads, was here beaten in the class for 100 heads by Mr. T. Pitt, of Colchester; so close was the competition for the premier position in this class that at one time we thought both deserved equal first. For 50 heads of Asparagus, Mr. R. Cheshire and Mr. Smith were placed 1st and 2nd, while Mr. F. B. Philbrick was placed 3rd, facts which show that Colchester must be regarded as one of the centres of good Asparagus cultivation.

KEW GARDENS.—We have rarely seen these gardens so beautiful and so full of interest as at the present time, particularly the open-air vegetation. The arboretum teems with numbers of trees and shrubs in full blossom, especially those belonging to the Rose and Pea families. Among the latter the finest are the *Robinias*, of which there is a full collection opposite the temperate house, and very fine isolated specimens near the flagstaff. The *Azaleas* and *Rhododendrons*, too, though now on the wane, are still worth seeing, the latest flowering varieties being, indeed, the most valuable. The herbaceous plant collection is full of gay and interesting plants, which, moreover, are doing their best to hide the ugly bareness of the recently formed rock garden. Visitors ought not to miss seeing the old Water Lily house, which is one of the most interesting houses of all just now, the Water Lilies being in full flower, including the new *Nymphaea zanzibarensis*. In the entrance porch to this house a bed of the huge *Amorphophallus campanulatus* is a fine feature, quite distinct from any other in the garden. The Orchid houses and adjoining stoves, too, are worth a visit, and likewise the Cactus house, in which some of the *Agaves* and *Dasylium glaucum* are sending up towering spikes through the roof of the house. The climbers under the roof of the conservatory (No. 4) are now at their best, includ-

ing *Clematises*, *Tacsonias*, *Fuchsias*, *Tea Roses*, *Loniceras*, all of which are in full blossom.

QUESTIONS.

5014.—**Celery maggot.**—I have a row of early Celery planted out and it is attacked by the maggot. Can any of your readers tell me what I am to do in order to stop its ravages?—G. W. C.

5015.—**Billbergias.**—Should these when showing a flower-spike in the bottom of a vase-like tuft of leaves be still watered? Should water be left in the same? and after flowering does the plant sucker and die? In full sun the leaves turn yellow; should they be slightly shaded?—GEO. NISBET.

5016.—**Gloxinia buds.**—I will thank your readers if they can tell me the cause of many of the buds on my *Gloxinias* growing blind. They seem right to a certain point, when the sepals immaturesly expand and the centre of the bud becomes hard, and sometimes turns black.—G. A. F.

5017.—**Stephanotis not flowering.**—Could some of your readers kindly inform me the cause of a *Stephanotis* failing to flower? It is planted out in a stove, and trained on the roof. It makes good growth, having covered one side of the roof, and it has only been planted about twelve months.—F. W.

5018.—**Water Lilies.**—Would some of your readers kindly tell me what kinds of Water Lilies I should put into two small ponds I have just made and cemented at the bottom in a very warm and sheltered spot—quite a Madeira climate? The ponds are about 4 yards by 2 yards. I have already the Cape Pond Weed (*Aponogeton distachyon*).—WELSHMAN.

5019.—**Freesias.**—What is the proper treatment of these charming bulbs after flowering? I notice on some of mine that what seem to be bulbs are formed in the axils of the leaves; are these of any use, and what is to be done with them? Others are seeding freely; can anyone kindly tell me what is to be done with the seed when it ripens, which, I presume, from appearances, it will do?—DELTA.

5020.—**Genista præcox.**—Perhaps some of your readers can answer the following question: Last year I had flowering at this time in the open border several plants of this *Genista* about the same time as the ordinary yellow and white Portugal Brooms, which are now blooming. This year none of the *præcox* is showing flower. Does the plant flower in our Scotch climate only once in two years?—D. M. H., Coldstream.

5021.—**Diseased Vines.**—I have in a small vinery with a south-west aspect two sorts of Vines, viz., Black Hamburgh and Lady Downes, which at present are almost in flower. Both Vines have been in perfect health these fourteen years past, but about two weeks ago most mysteriously Lady Downes showed symptoms of something wrong. The leaves turned partially yellow, and assumed the same appearance as they should do after their fruit has been long ripe; in fact, some have already dropped off, particularly about the base of the Vine. There does not appear to the eye any insect that might cause it. Can any of the readers of THE GARDEN give me any explanation as to the cause of the mischief?—G. J.

5022.—**Dying Cedar tree.**—Would any of your correspondents kindly inform me what I could do for a very fine Cedar tree which is dying? Its trunk measures 13 feet 7 inches. The tree is situated quite close to the road on one side; on another side stands a Fir tree about sixteen years old, 14 feet from it or thereabouts. The Cedar stands on a mound 4 feet high and 40 feet round, and the roots of the tree are now forcing their way above the ground. The lawn where the Cedar stands was levelled thirty years ago, which, I imagine, caused the Cedar tree to be higher as regards its roots than the lawn. This year no new shoots have appeared, and indeed a great many of the branches are quite bare. The soil here is chalk, but there are other Cedar trees doing remarkably well, and I am anxious to save this one if possible; therefore for any information on the subject I shall feel thankful.—B. P. O.

* * Our readers will greatly oblige by replying so far as their knowledge and observation permit to these questions. The title of each query answered should be prefixed to each answer, and replies will be printed in the department of the paper under which the subject falls. The questions that arise and must be solved are so many in these days, that it is only by a general interchange of ideas and experiences among practical men that we can hope to answer them satisfactorily.

SOCIETIES.

EDINBURGH BOTANICAL.

A MEETING of this Society was held the other evening in the Royal Botanic Garden, Mr. W. B. Boyd, president, in the chair. The treasurer submitted the annual statement of accounts, from which it appeared that the receipts had amounted to £876s. 2d., and the disbursements to £8514s. 10d., leaving a balance in favour of the Society of £111s. 4d. The funds belonging to the Society amounted to £301 18s. 8d. On the motion of Mr. Taylor, the council was authorised to expend a portion of the Society's funds not exceeding £120 in defraying their joint publication with the author of a work on the "Hepaticæ of the Amazon and Andes," by Dr. Spruce, one of the non-resident fellows of the Society. Mr. Geddes read a paper on a small typical botanic garden at Grange House School, Edinburgh. The object of this garden was to arrange in a small space types of the principal Natural Orders, exhibiting their relations as clearly as possible for teaching purposes. This served as a key to a large garden, and was specially adapted for schools. Every school might have such a garden at an almost nominal expense within the limits of an ordinary garden plot. Any waste place in a town, from one-eighth of an acre and upwards, might be used in this way. Mr. Robert Lindsay, curator, read his paper on the progress of open-air vegetation at the Botanic Gardens. Since their last meeting, he said, open-air vegetation had made good progress, yet it was still much behind, owing in a great measure to the dry state of the weather. During the early part of last month the temperatures were below the average, while during the latter portion they were considerably above it. The thermometer was at or below the freezing point on four occasions, indicating collectively 9° of frost. During the corresponding month of last year there was no frost recorded. On the rock garden 243 species and varieties of alpine and dwarf herbaceous plants had come into flower during the month, making a total of 416 for the season, while at the same date (the end of May) last year 492 were recorded as having flowered. Though late, the show of hardy spring flowers was really fine, and they were now forming well-ripened seed. Surface rooting and recently planted trees and shrubs have suffered greatly from the protracted drought. Still, it was seldom that such fine, well-developed foliage and abundance of flower were seen on most kinds of deciduous trees and shrubs as was the case this season. Mr. Irvine, Drum Castle, stated that a *Rheum nobile* grown from seed planted six years ago had flowered in his garden. The plant was a native of the Himalayas, and very rarely flowered in this country. The plant stem was just now 37 inches high. *Rheum nobile* flowered in the Royal Botanic Garden, Edinburgh, two years ago, and was figured in THE GARDEN (see p. 406, Vol. XVIII.).

ROYAL HORTICULTURAL SOCIETY.

NEW PLANTS CERTIFICATED.—In our report of the floral committee meeting at South Kensington last week we omitted to mention that the following new plants—all shown by Messrs. Veitch & Sons—were awarded first-class certificates, viz:—

HYDRANGÆA ROSEA.—A new Japanese shrub, and undoubtedly one of the best novelties in the plant way that have been exhibited in London this year. It resembles the common *H. Hortensia*, but is more slender in growth and has smaller foliage. The branches are terminated by large dense heads of flowers all sterile, as in the ordinary form of *H. Hortensia*. These flowers are of a lovely rose-pink, so clear and pleasing as to win the admiration of everyone both at South Kensington and at the Regent's Park Show.

ACER CRATÆGIFOLIUM VARIEGATUM.—A prettily variegated-leaved form of one of the new Japanese Acers recently introduced by Messrs. Veitch. Its leaves, as the name implies, partake somewhat of the character of those of some of the species of *Cratægus*. In the normal form these

are a deep green, with reddish stalks and veins; but in this new variegated variety they are mottled and flaked with white. This Maple is, no doubt, quite as hardy as others of the Japanese race.

ACER POLYMORPHUM VARIEGATUM.—An elegant form of this very variable Japanese Maple, having prettily variegated foliage.

EVENING MEETING AT BURLINGTON HOUSE.

We give the following list of the plants shown in flower at the evening meeting on the 12th inst. by Mr. Loder, showing as it does what variety and beauty one may have in the open-air garden in early June. Mr. Loder's garden is at Floore Weedon, Northamptonshire.

<i>Aquilegia chrysantha</i>	<i>Lychnis viscosa</i>
<i>cerulea</i>	<i>Pentstemon glaber</i>
<i>alpina</i>	<i>humilis</i>
<i>pyrenæica</i>	<i>Papaver alpinum</i> (white)
<i>glandulosa</i> (hybrid)	(yellow)
<i>Saponaria ocyroides</i>	(orange)
<i>Saxifraga Hostii</i>	<i>orientale</i>
<i>McNabiana</i>	<i>bracteatum</i>
<i>altissima</i>	<i>nudicaule</i>
<i>paradoxa</i>	<i>rufifragrum</i>
<i>incurvifolia</i>	<i>Gaaphallium Leontopodium</i>
<i>Cotyledon</i>	<i>Rhododendron ferrugineum</i>
<i>Wallacea</i>	<i>lepidotum</i>
<i>Carduus Benedictus</i>	<i>Narcissus Bulbocodium</i>
<i>Linaria alpina</i>	<i>poeticus</i> fl.-pl.
<i>pallida</i>	<i>Gentiana bavarica</i>
<i>Anemone decapetala</i>	<i>Euphorbia Myrsinitis</i>
<i>syvestris</i>	<i>Hen-and-chicken Daisy</i>
<i>fulgens</i>	<i>Aponogon distachyon</i>
<i>Convallaria bifolia</i>	<i>Ranunculus speciosus</i>
<i>Ononis rotundifolia</i>	<i>acutifolius</i> fl.-pl.
<i>Ethionema grandiflorum</i>	<i>Orchis chlorantha</i>
<i>pulchellum</i>	<i>mascula</i>
<i>Onosma tauricum</i>	<i>Cypripedium macranthum</i>
<i>stellatum</i>	<i>parvillorum</i>
<i>Trientalis europæa</i>	<i>Calceolus</i>
<i>Artemisia argentea</i>	<i>Veronica gentianoides</i> fol var
<i>mutellina</i>	<i>rupestris</i>
<i>Androsace lactea</i>	<i>pinguifolia</i>
<i>Hutchinsia alpina</i>	<i>saxatilis</i>
<i>brevicaulis</i>	<i>Bellidistram Michellii</i>
<i>Thalictrum foetidum</i>	<i>Isopyrum thalicroides</i>
<i>Rosa spinosissima</i>	<i>Aster alpinus</i>
<i>alpina</i>	<i>Calceolaria Kellyana</i>
<i>Ornithogalum umbellatum</i>	<i>plantaginea</i>
<i>Lindelia spectabilis</i>	<i>Geranium subcaulescens</i>
<i>Ajuga Brockbanki</i>	<i>tuberosum</i>
<i>Armeria grandiflora</i>	<i>sanguineum</i>
<i>juniperifolia</i>	<i>lancastræense</i>
<i>Mertensia sibirica</i>	<i>arvense</i>
<i>Viola pedata</i> alba	<i>Endressi</i>
<i>Geum minutum</i>	<i>Enothera pumila</i>
<i>strictum</i>	<i>Erinus alpinus</i>
<i>triflorum</i>	<i>a. albus</i>
<i>Pyrethrum hybridum</i>	<i>Campanula garganica</i>
<i>Scenecio Boronicum</i>	<i>Jamæia americana</i>
<i>Iris sibirica</i>	<i>Lupinus nootkatensis</i>
<i>germanica</i>	<i>Fehium rubrum</i>
<i>Phytolacca Chammelli</i>	<i>Hesperis matronalis</i> fl.-alb pl.
<i>betonicifolia</i>	<i>m. fl.-rub.-pl.</i>
<i>Caltha viridifolia</i>	<i>Digitalis purpurea</i>
<i>Primula farinosa</i>	<i>grandiflora</i> (yellow)
<i>sikkimensis</i>	<i>Astrantia maxima</i>
<i>luteola</i>	<i>major</i>
<i>Dianthus fragrans</i>	<i>minor</i>
<i>Simsi</i>	<i>Asperula odorata</i>
<i>alpinus</i>	<i>taurica</i> [omn]
<i>petraeus</i>	<i>Dracocephalum Ruyschia-</i>
<i>deltoides</i>	<i>Idolium tataricum</i>
<i>viscidus</i>	<i>Potentilla aurea</i>
<i>cæsius</i>	<i>ambigua</i>
<i>eruentus</i>	<i>rupestris</i>
<i>sylvestris</i>	<i>Reseda glauca</i>
<i>Myosotis Surprise</i>	<i>Eritrichium floribundum</i>
<i>Ranondia pyrenæica</i>	<i>Gypsophila cerastoides</i>
<i>Milla capitata</i>	<i>Phlox divaricata</i>
<i>Melittis Melisophyllum</i>	<i>Alyssum Wiersbecki</i>

English plant names.—Popular names, I find, cause a deal of confusion. For instance, the Bronze Leaf referred to by "Veronica" (p. 440) puzzled me as to what plant was meant till a lady (p. 500) elicited from "Veronica" the answer that it was *Rodgersia podophylla*, and then she suggested that a more appropriate name would be *Rodger's Foot Leaf*, thus making the application of English names a more matter of taste. Therefore, to encourage the adoption of such names without the Latin one would, as I have said, simply create confusion. "F. W. B." says (p. 469), is it not unreasonable to expect every amateur gardener to learn Latin names for all the plants which he grows in his garden? To this question I answer, no. Anyone who grows plants for pleasure will think it no trouble to acquire a know-

ledge of their Latin names, even if it needed double the time to learn them that it would English ones, which it does not. If scientific education is to prosper, we must become acquainted with its technicalities; if English names are used, Latin ones must also be employed along with them.—J. S.

* * No one, we believe, has advocated the disuse of Latin names—impossible at present. The position of "F. W. B." and others is that they should seek, for all plants likely to be grown in our gardens, an English name, leaving the Latin one to be used as occasion arises and when really wanted. This is only asking for what is already in use in the case of fruits and vegetables. There can be no doubt that a fitting English name is useful and pleasant to many who would never use or care for a Latin one. Unfortunately, some who are facile in the use of technical names cannot see the human side of the question. The very general deafness to long names seems a contemptible weakness to them; whereas, if thought over, they would recognise it as an important condition, and one which must be met.—ED.

New hardy Passiflora.—We send you a seedling hardy Passion Flower which we have now in bloom for the first time on the open wall. The plant is as free growing as *P. cerulea* and quite as floriferous.—LUCOMBE, PINCE & Co. [The flower sent is apparently not in sufficiently good condition to judge of its merits.]

In Madeira.—In THE GARDEN of the 21st April last appears an article thus headed. Could the author of that article mention the number of days required to reach England from Madeira, and also the best book on Madeira, which gives details of its climate, cost of living, &c.? Is there a British consul there?—E. B. *Etawah*, N.-W. P., India. [About four days. The best book is Miss Taylor's. There is a British consul.]

THE following has been communicated to us by the directors of the Crystal Palace Company: "Miss F. R. Wilkinson, a lady student in the landscape division of the Crystal Palace Company's School for the Improvement of Estates, has just been appointed a member of the council of the Kyrle Society, with a view to her specially advising in matters connected with the laying out and improvement of churchyards, gardens, squares, &c.—a beneficial department of the Society's operations. Mr. Sydney S. Marshall, who has just completed his course in the same school, has been appointed superintendent of works at Stoke for the new combined park and cemetery that is to be immediately laid out there."

Names of plants.—*E. H.*—*Allium Moly* (yellow), *Geranium sanguineum* (red), *Tradescantia virginica* (magenta).—*A. Wallace*.—It seems to be a variety of *Weigela rosea*.—*W. E.*—*Geranium sanguineum*, *Allium Moly* (yellow).—*J. Gray*.—*Staphylea pinnata*.—*J. B. Boyd*.—*Panocratum speciosum*.—*J. C. L.*—1, *Pentstemon glaber*; 2, *Saxifraga ceratophylla*; 3, *Cistus purpureus*; 4, *Campanula glomerata* var. *speciosa*.—*M. J.*—*Muscari comosum monstrosum*.—*T. Bunyard*.—1, *Allium neapolitanum*; 2, *Alonsoa incisifolia*; 3, *Dianthus plumarius* variety.—*Col. Wortley*.—1, *Rudbeckia hirta*; 2, apparently *Pentstemon speciosus*; 3, *Erigeron* next week. —*C. A. (Sub.)*.—1, *Passiflora* or *Tæsonia*; 2, *Stantonia hexaphylla*; 3, *Passiflora*; 4, *Chorozema*; 5, *Ficus diversifolia*. Send Nos. 1, 3, and 4 when they come into flower. —*C. H. Weston*.—1, *Geranium lancastræense*, a variety of No. 2; 2, *G. sanguineum*; 3, *G. nodosum*; 4, *Geum montanum*.—Flowers in flat box with no name and no numbers attached.—*Geranium*, *Eriostemon*, *Valeriana alliariæfolia*, *Euphorbia corollina*, *Iris squalens* var.

GARDEN APPOINTMENTS.

CHRISTISON, Mr. Wm., has been appointed as gardener to H. G. Bainbridge, Esq., Woodham Hall, Woking, Surrey. CLARKE, Mr. John, as gardener to R. E. Wemyss, Esq., Wemyss Castle, Fife. DUNCAN, Mr. Thomas, as gardener to Lady Gordon Cathcart, Titniss Park, Sunninghill, Berks. GODDARD, Mr. William, as gardener to R. Ketchell, Esq., Newton Park, Burton-on-Trent. HUTCHINSON, Mr. A., as gardener to Mrs. Russel, of Plassy House, Limerick, Ireland. KNIGHT, Mr. Henry, as superintendent of the parks and gardens of his Majesty the King of the Belgians, at Laeken, near Brussels. MASSON, Mr. W., as gardener to Miss Goolders, The Grove, Cookham, Berks. MILNE, Mr. Charles, as gardener to the Earl of Rosslyn, at Dysart House, Fife.

"This is an Art
Which does mend Nature: change it rather
THE ART ITSELF IS NATURE."—*Shakespeare.*

EARLY SUMMER ON THE HUDSON.

ASIDE from the many historic memories which seem for ever winding in and out of every bend and sweep of this graceful river, there is untold beauty in the charming valley through which it flows; and just now in June these banks and margins of this broad and ample waterway are clothed in a shower of glory such as no one can understand or imagine who has never looked upon it at this season. Those who have been fortunate enough to sail up or down the Hudson on one of its elegant steamers by a June daylight will remember the picture through life. Beginning with the high vertical wall of rock on the left as you leave New York Bay, with its narrow strip of green foliage at the base and border of the same at the top, where it touches the sky, and the velvety lawns of the pretty villas which adorn the river margin of the upper portion of Manhattan Island on the right, you glide rapidly on, as if sailing upon a ribbon of burnished silver, fringed on either side by most exquisite leafage. As the picture lies unmoved in the still water ever and anon at the vessel's side you gaze upon its lovely details enraptured. The scene is ever changing as you proceed, and there is no thought of monotony as so frequently suggests itself in river landscapes. Here, for over a hundred miles, Nature spreads on either hand a panorama of varied character and continuous beauty. Now, you gaze upon towering mountains, whose bases lie far down beneath the steamer's keel perchance, and whose rugged sides are a wild tangle of rocky grandeur, charming shrubbery and forest; now, you have a table-land gently sloping to the water, with green meadows dotted here and there with suburban mansions, pretty villages and hamlets, with church spires gleaming through the foliage and glistening in the summer sunshine, and, anon, you see rolling hillsides that make the slopes, the nooks, and the rich valleys where the farmer has planted his gardens and his orchards, which of late have made the entire locality a vast flower garden, fragrant with blossoms and bountiful with promise. After a few hours of this and more which I cannot even outline, a range of beautiful mountains looms up on the distant left. At first, far away, resting beneath the blue haze of the intervening atmosphere; but, soon after, you glide nearer and are enabled to study the numerous peaks more in detail. They are

THE CATSKILLS, now arrayed in fresh summer garments, throwing open their doors to tired humanity and tourists of every land. They rise abruptly in the air, some to a height of 4000 feet and more. A few of the peaks facing the river are dotted with huge white hotels plainly visible from the vessel's deck. Now you see village church spires in the foreground outlining themselves against the precipitous sides of the distant mountain, and then green and beautifully wooded foothills appear in the front, and thus continues the charming scene which greets one's eyes as we sail up the Hudson in June. Every flashing bubble of the silvery stream reflects the beauties of its leafy margins, and the music of each tiny wavelet adds harmony to the picturesque symphony of natural grandeur. If asked to particularise, I would not stop at the stiff architectural conceptions and productions of art. There are plenty of these all along the river. Money has been expended lavishly, and landscape engineers have wrought out their geometrical ideas with abundant effect. But in all this there is no beauty for me; the grouping of unassisted Nature is far more graceful and pleasing. She presents no cold fixed lines upon which the eye must rest with discomfort, no hard angles that jar upon the senses. I would point to the

graceful grouping of forest, hill, and vale, the clumps of shrubbery and foliage, and the gradations of colour, the fresh and tender green of the new growth on the Hemlock, the darker shades of the new leaves on the Oak and other deciduous trees, the luxuriant wreaths of Clematis, Ivy, wild Grape, and the numerous wild climbers that twine so beautifully among the branches that grow upon these river banks; and

THE ORCHARDS AND SMALL FRUIT GARDENS, where are they more beautiful, more vigorous, or more fruitful than in this fertile valley? The growers are proud of them; the very soil in which they stand seems honoured in their production. All are now laden with young fruit, and there is promise of an abundant yield. A portion of the western shore is extensively devoted to Peaches, for which the locality seems peculiarly adapted. These trees are now heavily fruited. Strawberries are already ripening, and the crop will be immense. This vicinity is also the home of the Raspberry; large fortunes have been made in years past by the growth of this fruit here, and nowhere else perhaps is the Raspberry grown so largely and successfully. Grapes are also grown here to an enormous extent, and one sees vineyard after vineyard on the banks stretching away as far as the vision extends at times. Currants and the whole class of open-air fruits are also largely cultivated, and this river valley is in truth one of the most fertile and productive fruit gardens in America. The growers make money and live in neat, well-kept houses which are often large and attractive. Enterprise and thrift greet the eye everywhere along the river. Among the residents are many names of eminence and renown; famous artists, inventors, scientists, journalists, philanthropists, pomologists, railway magnates, millionaires, preachers, and some of the most distinguished men of the country in every calling have erected elegant dwellings along the Hudson, where they reside most part of the year; and who will say they have not located wisely?

Kingston, N.Y.

H. HENDRICKS.

PICKING PEAS.

MUCH injury is often done to the Pea crop by careless gathering, especially in the case of late Peas, which are expected to continue in bearing longer than the early white round varieties. If the haul is carelessly handled or bruised, that successional character which many of the Marrow Peas possess is injured, or perhaps destroyed. If every Pea pod was gathered just at the time when it became fit for use, and if the plants were as vigorous as they ought to be when well grown, successional crops equal to, if not superior to, the first would be produced. Peas, like all other seed-bearing plants, will, so long as life remains, strive to perpetuate themselves, and it is interesting to watch the struggles which a plant will make pushing forth crop after crop of blossoms in order to fulfil its destiny; hence the importance of gathering the pods early before they get too old for use. The same principle should be acted on in the case of all kinds of legumes.

E. HOBDAV.

HARDY FERNS FOR SHADED GARDENS.

ONE frequently hears the remark made that plants do not succeed in certain gardens, but on inquiry it generally turns out that the plants selected have not been suited to the positions they occupy. Although some plants delight in abundant sunlight, others are equally at home in deep shade, and it is only by observation as to what conditions are most favourable for certain plants, and selecting them accordingly, that success can be achieved. In this locality, wherever the situation is open to sunshine, bright-flowering plants are the favourites, and thus many of our villa gardens are kept gay nearly the whole year round, the latest Chrysanthemums not being long removed before early flowering bulbs and many other plants are in blossom. But all gardens cannot have full south aspects, and it is refreshing on bright summer days to find instead of summer bedding plants

gardens in shady places filled with the verdant foliage of hardy Ferns and of other plants that dislike sunshine. When well established it is surprising how effective even the commonest of our native Ferns are planted in shade, and how beautiful they make many an otherwise uninteresting corner look; even little borders by hard paved yards or ground beneath large trees where nothing else will grow may be made cheerful by means of Ferns. Get together a few of the largest and roughest stones that can be obtained, and a load or two of good soil; make irregular mounds here and there, and on these plant the Ferns. Intermix with them a few dwarf trailing plants, keep them well watered, and they will soon produce a striking effect.

J. GROOM.

ROSE GARDEN.

THE ROSE HARVEST.

"DELTA" in writing on this subject seems in a most hopeful mood, and, judging by his reference to Mr. Fish's statements about injury done to the wood, appears to think that the latter has been too desponding; this may seem so to "Delta." The losses, however, which we had here in March and the injury done to those left have not, in my opinion, been at all exaggerated by Mr. Fish. No wood on the "cut-backs" was left sound, and, indeed, what little we thought healthy succumbed during the hot, sunny days in May and early June. Such terrible slaughter we never saw before so late. I quite agree with Mr. Fish that the blooming season with good Roses will be late. Looking to a brighter side, perhaps, Roses never recovered themselves so quickly, that is those left alive. Of dormant eyes, we lost many, both dwarfs and standards. I, however, agree with "Delta" that Roses never were so free from fly or grub as this season, but to say that they were not injured and killed in March, and have died since, is, so far as my experience goes, wrong. As to A. K. Williams, we have it in the form of standards, half standards, on the Manetti and seedling Briers, and among all our Roses it is the worst we have on the standard and half standards, more than 75 per cent. succumbing to the March winds. On the Manetti and seedling Brier we find it, too, equally tender, and not nearly so hardy as many of the stronger Teas.—W. H. FRETTINGHAM, *Beeston, Notts.*

—A distance of nearly 200 miles must intervene between the gardens that Mr. Fish and I manage. His is in East Anglia; that from which I write is in West Somerset, a county reputedly notable for mild winters and favourable summers, which may, I grant, be true in part, but I must say I have not, after sixteen years' residence in it, found it much more favourable than most of the home and eastern counties. In respect to Roses, the neighbourhood of Taunton seems to be no more favourable than that of Bury St. Edmunds, for the condition of our Roses is anything but satisfactory. It is true I have hardly any deaths to record through the severity of the weather in March last, but I have abundant evidence in the shape of dead and dying branches and plants nearly killed to show that it has left its mark behind it; and if the Roses about which Mr. Fish has written have suffered to the same extent, he has not in any way exaggerated the amount of mischief done. "Delta" does not appear to have much sympathy with growers less fortunate than himself. But if he has any doubt about the injury that the frost has inflicted on Roses, I think dead branches and a score or two of nearly dead plants that I could send him would convince him of the truth of the matter. Once satisfied as to the losses sustained, he may then be able to discover how it is that Roses have suffered more in one garden than in another, and in places at wide distances apart. It is pleasant to turn from the afflicted Roses to those in fairly good health, for we have some such, and they are own-root plants put out in beds with their branches pegged down. These, although somewhat weaker than usual, are flowering well, and not a branch was injured by

the spring frosts, a convincing proof that in gardens where Roses are liable to injury from inclement weather they should be pegged down. In this way they will pass through a trying time much better than standards or what is known as dwarfs. —J. C. C.

—“Delta” might, I think, have expressed more sympathy than he has done with a brother rosarian with whom March has dealt harshly enough. Living, however, in the garden of England (Kent, possibly), and travelling southwards, his experience would naturally be different from that of one living in the east, and oftener than not wandering northwards. He seems, indeed, to be one of those fortunate mortals whose Roses have all been left in the most robust health and highest promise of first prize blooms. Last March, one of the most disastrous seasons to rosarians ever experienced, has been just to his mind, and woe be to the scribe or prophet who writes otherwise. It gratifies me to find that “Delta’s” experience and correspondence differ so widely from mine. It is sweeter far to me to agree with “Delta” than to lecture him for differing from me. And so I go on to note the wonderfully good effects of recent rains on the Roses. Time will soon reveal the true character of our local Rose blooms. To-day Diss is holding its show; on Thursday, the Bury Society has its meeting; on the 5th, Norwich and Woodbridge will show Queen Rosa together; on the 12th, Ipswich will do her best to eclipse all previous doings of her neighbours. These are but samples of the numerous little goes in the provinces that do so much to foster the culture and strengthen the love of the Rose among all classes of the population. —D. T. FISH.

—My experience is in direct contradiction to that of “Delta” as regards his *rosy* statements, and I must endorse Mr. Fish’s view of this, up to the present time, most disappointing season. Here, some ten miles north of London, we have gone through an unusually mild winter, and everything went well until the 7th of March, when severe frost set in, accompanied by strong winds from the north and east, which continued with little intermission through the month. Apricots, Plums, and early Pears were cut off, and we are only now realising the results of the cruel spring weather upon our Rose trees. As your readers are probably painfully aware, the east wind blows no good with it, and as it has persistently prevailed for the last three months, we have been favoured, or I should rather say scourged, with nearly every description of insect pest. I well remember the plague of leather-jackets or bots, the larve of the crane fly or daddy-longlegs (*Tipula oleracea*) in the north of England in the year 1880, and the amount of mischief caused by it, but we have never before been afflicted with this troublesome pest until the recent spring, when we have literally destroyed thousands of it, but unluckily not before they had killed our *Echeverias* and other plants by wholesale, and made ugly bare patches all over the lawn. The hedge-rows in fields and the herbaceous borders in gardens simply swarm with cuckoo spit. Our variegated *Ivies* have been to a great extent covered with black fly; and had it not been for the indefatigable perseverance and job-like patience of my floricultural chief, we should have had almost everything eaten up by the green aphid, the prevalence of which has exceeded anything within my recollection. —WINCHMORE.

Rosa Harrisoni.—Mr. Fish alludes (p. 537) to the free flowering habit of the almost unpruned branches of this Rose. Has he ever grown it as a dwarf plant without being pruned? If he has not, I can promise him he would be still more delighted with it in that form. We have two such plants that were planted nearly eight years ago. They have never been pruned, but have been allowed to grow as they pleased, and one especially has grown in a much more satisfactory way than ever I have seen this Rose do. As a standard it generally grows weakly, but as a dwarf on the Manetti stock it makes one of the most charming bushes imagin-

able if the pruning knife is kept from it. Grown as we have it here, its graceful arching branches render it a very conspicuous object, and the freedom with which it flowers in an unpruned state is something wonderful. The length of time during which it continues to flower is not the least of its merits; with us it flowers more or less for at least two months, and it is as early in coming into flower as any Rose we have; moreover, it is the only Rose except *Gloire de Dijon* that was not more or less injured by the cold weather which we experienced last March. —J. C. C.

FRUIT GARDEN.

ROOT-PRUNING.

In countries where the climate is favourable to the production of fruit—that is to say, where the heat and light and moisture are properly adjusted—root-pruning is not needed, as these agencies all work smoothly together to the same end. Root-pruning is a necessity incurred through an unsuitable climate and other causes, under which trees grow over-luxuriantly at the expense of fertility. For example, the Peach tree under glass in this country requires less root-pruning than it does out of doors, because in the former case, however rich the soil may be in which the roots are placed, the branches enjoy a higher and more suitable temperature, and are consequently better ripened every year; and ripe and fruitful wood is the main object of root-pruning. Outdoors, in this country, all tender fruit trees, including the finer varieties of the Apple and Pear, penetrate deeply into the soil, if they have the chance; and as deep soils are longer in being warmed in spring than shallow soils, and longer in cooling in the autumn, the consequence is that trees are late in starting into growth, and grow late into the autumn, so that they cannot ripen their growth properly, and hence do not bear fruit as they should do. Root-pruning—which does not so much mean pruning the roots as lifting them and bringing them nearer the surface within the influence of the sun’s heat and the air—is designed to prevent this state of things. Trees growing in deep or heavy and rich soils make many and strong roots, which produce corresponding strong and unfruitful branches. When such roots are lifted and shortened and laid in nearer the surface, the growth of the tree is earlier, better ripened, and more fruitful. There are often, however, cases in which failure to bear fruit is not due to over-luxuriance, and cultivators should be careful not to make any mistake on this head, as many, it is to be feared, do. Trees usually fail in fertility through over-luxuriance, high living, or poverty; but it is easy to tell which of these is the cause. Root-pruning is, as a rule, practised only on over-luxuriant subjects, which clearly enough indicate the need of it in their growth. The shoots are rank, strong, and barren, rarely producing fruit buds except at their extremities. Such trees are suffering from plethora, and the way to make them fruitful is to starve them in some degree. Poverty, which is often a cause of barrenness also, has to be dealt with in the opposite way. The trees must be fed, but of these we shall speak further on.

THE SEASON TO ROOT-PRUNE.—Root-pruning may be practised at almost any season of the year on Apples, Pears, Plums, Peaches, Cherries, &c.; but the proper season is when the leaves are on the tree, any time after June, when the current season’s growth has grown a bit hard—at least when severe pruning has to be practised. Many root-prune after the leaves have fallen, which is a safe practice; but it means the loss of a year, as the effects of the pruning are not felt until the second year following. Late root-pruning checks the growth the next season, but it usually also destroys the chance of a crop at the same time. On the other hand, by pruning early the growth of the current season is checked, resulting in the production of fruit-buds in the autumn and fruit the next. The check administered simply converts leaf-buds into fruit-buds, and; the root-pruning

being done when growth is only in progress, the buds are capable of being modified either way. Trees which need operating upon should now be examined. It is advisable to prune before the trees get too luxuriant and barren, as they are then more easily managed and kept in bearing. When a tree has been bearing well, and then begins to grow more strongly, and at the same time is less productive, it is time to root-prune, and little pruning will then suffice—a mere cutting round the outside roots almost—as the gross roots will not then have travelled far out of reach. Unless it is suspected that tap roots have gone down under the bole of the tree, the most that will be required will be the digging of a trench round the extremities of the roots a good way from the trunk, and lifting the roots up and cutting their points. This will give a sensible check to the tree without injuring the crop of fruit, if any. But if tap roots exist, such a pruning will do very little good. Tap roots are only likely to be found near the trunk, and they will be thick, strong, and carrot-looking, diving deep into the subsoil. They must be sought for carefully, by removing as much of the earth from the roots as can safely be done, till the block of soil near the trunk is reached, when it will be found practicable to excavate under it, and cut any roots off that may be found. In the case of established trees pruned when in leaf, it is not safe or wise to uncover the whole of the roots; a good ball of soil should, however, always be left untouched, according to the age and size of the tree. It may be scooped out underneath all round, to make sure no roots are going down, but not meddled with further, otherwise the check to the tree while in leaf may do it serious permanent injury—kill it, in fact. Summer root-pruning requires to be carefully performed. After the leaves have fallen it is different, as then any tree, no matter how old it is, may be lifted clean out of the ground and set down again, so long as plenty of roots are saved. For these reasons it is better to put off root-pruning of very strong-growing old trees that have not been disturbed for a long period till November, and do the work thoroughly then. The pruning of the roots really consists principally in cleaning their points with a knife. The most careful workman will fail to save all the roots. Many will be lost, and the first point with such as are got up safely is to lay them down again safely, about 9 inches or 1 foot from the surface. Young bush or pyramid trees are much more easily managed than old trees. As a rule they make a mass of roots, and if root-pruned every two or three years in a regular way, they experience but little check from it, no matter at what season it is performed.

PRUNING THE BRANCHES OF ROOT-PRUNED TREES.—Mistakes are often made in this direction. It is a frequent custom to prune the top of a tree at the same time that it is root-pruned, whereas it would be better to extend it if possible. The root-pruning is designed to reduce the supplies; but when we prune the branches back at the same time, we also reduce the demand, and the tree is just in the same state as before, or nearly. Vigorous-growing trees may be thinned out in the branches as far as necessary to let the air and light in amongst those which are left, but no further pruning is needed. Shoots 4 feet or 5 feet long, one season’s growth, we have seen left after root-pruning, and at the end of the next summer they were clothed with fruit buds from end to end, while making scarcely any terminal growth. This is as it should be. The temporary cessation of terminal growth, or of the production of young shoots is the first noticeable effect of root-pruning. When, however, the tree is cut back in its branches as well, it will push vigorous shoots that will not be fertile. Wall trees should be spread out, and any shoot laid in that room can be found for, and they will all produce fruit the year following, or next again, just according to the season at which the roots were overhauled.

ROOT-PRUNING FEEBLE TREES.—These have to be managed in quite another way from strong-growing subjects. The feeble old Apple, Pear, or

Cherry tree is a common spectacle in old orchards. It has just strength to put forth leaves every year, and probably quantities of blossom, but it extends its branches very little, and bears nothing like the crop it gives promise of, and the fruit is always inferior. Not much can be done with very old trees of this description, and they are, as a rule, better replaced by young ones; but quite often, also, this feeble state occurs in comparatively young trees, and results from the roots being placed in a bad or poor soil, or perhaps by their getting down into a bad subsoil. There is always good hope of restoring a feeble tree to comparative health and vigour while it is observed to make fair foliage to the extremities of its branches; but when the points of the shoots look sickly while in growth, or when they keep dying back, it is a bad sign, and, in the case of all such, restorative measures at the root must be accompanied by free cutting back of the shoots so affected to the sounder wood. The root-lifting in any case must be carefully performed, for few really strong roots will be found. If it is suspected that the roots have gone down into a poor or bad subsoil, they will have to be searched for and brought up, or cut away; but every root should be saved if possible, and all brought up within 18 inches or a foot of the surface. Those roots already near the surface should be uncovered, but not lifted, and the whole should be top-dressed with good, wholesome, fresh soil and manure, keeping the latter, if it is fresh, from actual contact with the roots. It will be a year or two before any good effects are noticeable; they will be seen in the broader and better foliage produced and greater growth.—*Field.*

MARKET FRUITS AND THEIR PRICES.

It is certainly not the fault of fruit growers that the public are unable to obtain first-class fruit at moderate prices. I notice in *THE GARDEN* (p. 551) that you say Tomatoes are making from 2s. 6d. to 4s. per pound, and in the same paper, under Covent Garden Market wholesale price list, Tomatoes are quoted from 9d. to 1s. per pound. Middle men, I know, make large profits, but if they buy at from 9d. to 1s. and sell at from 2s. 6d. to 4s., it not only discourages the grower, but prevents the public being such large fruit consumers as they would otherwise be if they could obtain fruit at moderate prices. It seems they now have to pay three or four times as much as the grower obtains. Until the middle man is content to take less profit, or the grower can supply the consumer direct, fruit will be unattainable at moderate prices. Neither can I agree with Mr. Gilbert in his remarks (p. 530), under market fruits, that "we only want size, colour, and croppers." My experience is that flavour and colour are the chief considerations in fruit growing, and that a medium-sized fruit, well ripened and coloured and fine in flavour (particularly in Tomatoes), finds a readier sale than monstrous, flavourless varieties. Very large, dull red Tomatoes, are inferior to fruit grown from well-selected seed of Hathaway or Old Red, which both bear large crops of well-shaped, highly-coloured, and finely-flavoured fruit. J. W.

Ridgeway Vineeries, Malvern.

5002.—**Mulching Strawberries.**—Hay is objectionable on account of the quantity of seeds that it brings into the garden, as well as the rapidity with which it decays, especially in such seasons as the past two have been in many parts. Short Grass or the mowings of the lawn are preferable, but better than all is short stable litter. Tan answers very well where it can be had for the carting.—W. P. R.

— "J. H." says (p. 530) that small wood charcoal is the best thing to spread over Strawberry beds, but how are we to get it? Not nine gardeners out of ten would be allowed to purchase it. It is far too expensive to use in any quantity. Long stable litter, as "A. D." rightly remarks, becomes quite sweet if laid down soon enough, but those who object to this will find clean, fresh straw a cheap and excellent substitute.—DONALD.

5002.—**Litter for Strawberries.**—No; bad hay will not do as well as straw as a litter for Strawberries, for, in the first place, the ground would soon be green from the seeds, and next, both seeds and the harder particles of hay would adhere to the ripe fruit. The best of all mulching for the purpose is long stable litter, with the droppings shaken out of it, only it should be applied early that it may get washed by rain before the fruit is ripe. We always put it on at the time when the beds are given their winter dressing, which dressing is as follows: The beds are freed of runners and decayed foliage, then the surface soil is lightly pointed over and a coating of rotten manure (cow manure is best) spread over, and on this the long litter, this completing the whole of the culture required except keeping the beds free from weeds by hand-weeding.—W. W. H.

Fruit preserving.—As difficulty is often experienced and expense incurred in collecting fruit baskets from the country, is it not strange that factories for preserving fruit on the spot where grown are not more numerous? I would suggest that this district, in and around which so much fruit is grown and sent away, would be a good centre for an enterprising firm in the trade to erect a factory for preserving and packing fruits and vegetables on the spot, thus saving the cost and carriage of baskets to and from London, with the advantage of being able to treat the fruit in the best stages of ripeness, without the deterioration consequent on delay in transit.—CHARLES GANE, *Wishcach.*

Peach culture.—In the gardens of the Earl of Wharcliffe, Wortley Hall, there has been and is being gathered at the present time from one comparatively young Victoria Nectarine tree about forty dozen fine fruit; they were mostly counted on the tree and might be a few more or a few less. From one Royal George Peach of the same age, in the same house, there was gathered between the middle of May and middle of June a nearly equal number of such fruit as would have fetched the highest price in the London market. In 1882 the same Nectarine bore twenty-nine dozen odd; in 1881 over twenty-two dozen, and the Peach a proportionate quantity, not to mention previous years. These trees have latterly been rapidly extended on Mr. Simpson's extension system. We have tested the flavour of the fruit thus grown and find it almost different in kind from the very best fruit sold in Covent Garden and much superior. The flavour of market Peaches is a puzzle to us. To give from £1 to 30s. a dozen or more for lumps of flavourless matter is a way of spending money that even millionaires might tire of.

The Gooseberry crop.—In many places Gooseberries are thin this year, owing to the length and coldness of the spring, which caused many of the blossoms to fall off, and the crop was still further thinned after the fruits were set by the cold weather. Last year it was an easy matter to gather a bushel of berries from a single bush, but this year pecks will be nearer the average than bushels. Still, there are gardens in which the bush fruits are plentiful, although their number is limited. In a garden with which I am acquainted in the Fens not far from where I am writing, some three or four acres in extent, bush fruits are planted as a bottom crop, and are heavily laden with fruit; perhaps the shelter afforded by the top crop—Apples and Pears—may have helped the Gooseberries to weather the storm. Anyone planting a fruit garden where the site is warm and sheltered might, by having Gooseberries for bottom growth and Lord Suffield and Red Quarrenden Apples as a top crop, make it pay well. The Gooseberries might be gathered green, and so give the bushes a long rest, whilst the Apples, which are sure bearers, at least as sure as any Apples can be, would be gathered and turned into money before winter, and the anxiety and bother of storing thus avoided.—E. HOBDAV.

Early Saumur Frontignan.—My attention has been called to a paragraph in *THE GARDEN* of June 2 respecting this Grape, which was shown by me at the late Manchester show—

not "Early Smyrna Frontignan," as stated. In answer to "J. S. W.'s" request for me to furnish the history of this Grape, I cannot, perhaps, do better than quote the description given of it in the fourth edition of "The Fruit Manual": "Early Saumur Frontignan (Muscat de Saumur, Muscat Hâtif de Saumur, Madeleine Musqué de Courtiller, Précoce Musqué).—Bunches, small, shouldered, and very compact; berries, medium-sized, round, frequently very much fattened; skin, thin, beautifully transparent, white, assuming an amber tinge towards maturity, and marked with tracing of Russet-like Royal Muscadine; flesh, firm, rich, sugary, and juicy, with distinct Muscat aroma. A first-rate and very early Grape, ripening with the Black July, from seed of which it was raised. The Vine is an abundant bearer, and may be grown either in a cool vinery or against a wall in the open air, and it is valuable for pot culture. It was raised in 1842 by M. Courtiller, of Saumur, from seed of Ischia." I do not understand how "J. S. W." and others came to the conclusion that Early Saumur Frontignan is synonymous with Royal Muscadine or White Frontignan. As a matter of fact the three sorts have little or no resemblance to each other.—J. M'INDOE, *Hutton Hall, Guisborough.*

Air roots on Vines.—I think "W. W. H." (p. 564) will find that the cause of air roots on Vines is too damp and stagnant an atmosphere, and not, as he thinks, the inequality of temperature between root and branch. They will make their appearance on Vines planted in inside borders just as freely as on those planted outside if the house is kept too close and damp; and their presence on early forced Vines more commonly than on later forced ones arises, in my opinion, from the scarcity of fresh air and the excess of moisture necessarily maintained to counteract the effects of so much fire heat required at that cold and early season. Air roots, in my opinion, are a sure indication that a more buoyant atmosphere is required for the health of the Vine, as the leaves assume a healthier look and thicker texture very soon after more air is given, and the progress of these roots is then arrested.—DONALD.

NOTES.

ROBBER PLANTS.—Complaints against certain plants of an aggressive character—plants of robust habit, ever longing for more elbow room—are loud and frequent, especially so from amateur gardeners. We all know how the dainty Androsace, the blue Gentians, the dwarf turquoise-tinted Eritrichium, or the choicest Primulas succumb to the insidious advances of white Arabis, of mossy Saxifrages, or of purple Aubrietias whenever these last are once allowed to obtain a footing near them. In the herbaceous borders it is the same. Asters, Caucasian Comfrey, Golden Rods, Polygonums of the P. Sieboldi type, and such climbing plants as Calystegia dahurica or C. sylvatica soon make short work with more delicate neighbours—they are the Thugs of civilised plant life, the pariahs of the garden, and the gardener's exception to Darwin's rule as to the "survival of the fittest." For is it not true that, from the gardener's point of view, those plants which survive after any too close competition are not the fittest, but rather the most unfit? Hence in all good gardens the gardener watcheth well for these wolves among the lambs of his flock, and slayeth them

*

PLANTS RAMPANT.—Some of these robber chiefs are, however, so noble in form, so commanding in stature, or so graceful withal that they may be tolerated in odd corners, in half wild places, or on the turf which is mown regularly round them, so that no extra trouble has to be undertaken in the restriction of their tastes for travelling about. There are few more graceful plants for isolating on the turf in this way than are the Polygonums, especially P. sachalinense and P. Sieboldi; so also Calystegia dahurica or the Hungarian C. sylvatica cease to be troublesome weeds, or Thug-like stragglers, when planted on the turf in sunny corners, or allowed to disport themselves on a

dead bush or on a rude trellis of Larch branches in positions where they can do no harm. A good bold mass of *Lathyrus grandiflorus*, or of *L. latifolius albus* planted out in deep rich earth on the grass, only requires a few Fir branches to clamber over, and will then become quite a charming feature, as indeed they will without the branches, wreathing themselves about in the most graceful way on the shaven turf, but of all foliage plants for growing on grassy lawns, commend me to Iris germanica and Plantain Lilies (*Funkias*) of all, but especially of the best kinds.

*

MISTLETOE BERRIES are now and then procurable even in June, and this is the best time to rub them on to the smooth bark of the Apple or of Lime trees in order to propagate the plant. I know berries are obtainable at so late a date, because I gathered some to-day in an old garden, where, although birds of all kinds are plentiful, they had not stolen the viscid pearl-like fruits. There is no difficulty in getting the seeds to vegetate at this season; indeed, a close examination now shows the little green sprouts pushing out at two of the three angles of the sticky or slimy coated seeds. Many people try planting the berries at Christmas time, but they are unripe at that season, and failure is the natural result. The bark of the foster parent or tree, whether of Lime or of Apple, should not be cut, slit, or punctured in any way. If this is done, the sides of the slit or cut begin to decay and dry up, leaving the seed in contact with dry dead tissue on all sides, and again failure comes as the only reward. The right way is to place the whole berry between the first two fingers and to rub it up and down the smooth bark of branch or bole until it naturally adheres, which it will do firmly by its own viscosity.

*

THE GREAT YELLOW GENTIAN.—Gentians are so often dwarf and blue-flowered that one almost forgets that the medicinal species—the giant of its race—is a really good, large-leaved, robust-growing plant, well worth a place among ordinary hardy herbaceous plants, and not at all difficult to raise from seeds if sown as soon as they are ripe in autumn. It is now flowering here quite freely, bearing whorls of yellow flowers on stout stems 3 feet to 5 feet in height. These stems rise from a tuft of leaves, which are themselves bold and ornamental, being indeed not unlike those of *Veratrum nigrum* in form and venation. Speaking of *Gentiana lutea* reminds me of a native bog or aquatic plant of the order not often seen in gardens, although it well deserves to be naturalised beside pond banks or near ornamental water. This plant is *Menyanthes trifoliata*, the Buck Bean or Bog Bean of popular nomenclature, and one of the prettiest of all our native wild flowers. In some districts an infusion of its leaves and stems is used as a tonic, just as natives of Southern Europe use an infusion of Gentian. Both are as useful for their beauty as valuable for their medicinal usage.

*

THE COLUMBINES.—Both species and varieties are now most lovely, and well high as fashionable as the Daffodil of springtide. We get a supply of seed from Mr. Thompson, of Ipswich, every year, and it is rarely that an expenditure of a few pence yields such good interest. In habit and floriferous growth *Aquilegia chrysantha* is by far our best, although in our soil *A. californica* and hybrids between that species and *A. chrysantha* run it very closely. A very good kind also came to us from the Pyrenees in the shape of seed three years ago. It is robust and floriferous, of branching habit, a yard or so in height, having short-spurred dark blue flowers. I am not sure whether *A. cerulea* var. *pyrenaica* is the correct name, but as such we received it and were thankful. *A. glandulosa* is as beautiful as capricious here with us; its flowers are large and lovely, but, alas! why so "few and far between?" Our soil is light and sandy, so that the plants must needs root deeply for support; perhaps this accounts for the plants being short-lived with us, and this may also be the reason that they bear removal or transplanting

badly with us. No doubt as a class they grow best in good strong loamy soil containing plenty of fibre. Where may the finest seeds be obtained?—that is the question.

*

BULBOUS IRISES.—The Niphion section of the genus Iris is now yielding a glorious harvest, of colour and of graceful form. They do not succeed permanently on cold, wet soils, but then imported bulbs are so cheap that everyone may grow them. A thousand or two bought every year and dibbled into beds or borders with a handful of sand to each bulb would ensure plenty of flowers for cutting during June and July. They take up little room and may be planted near the most delicate of plants without injuring or overshadowing them, and no other flowers of this season surpass them in effect. The Clouded or Thunderbolt Iris is now especially beautiful, as are also some pale blue and yellow varieties of the Spanish race. Here and there the great blotched petals of the English Iris are opening to the sun like great blue butterflies, but these will not be at their best for a fortnight or more. Cut in the bud stage and brought indoors, few flowers are more beautiful; indeed they quite rival the choicest of Orchids alike in grace of form and in purity of colour. Tulips, Iris, Gladioli, Poppies, and Daffodils in the open air and sunshine are none the less beautiful than Orchids in a glass-roofed shed.

*

NON-BLOOMING BULBS.—I do not know how it may be in other gardens, but here, where many bulbs grow and bloom exceptionally well, there are some few which fail to do so. *Iris tuberosa* (Snake's-head Iris,) grows like a weed and increases rapidly, all the while refusing to bloom. So also has it hitherto been with *Sternbergia lutea*, *Iris Susiana*, and *Belladonna Lilies* (*Amaryllis Belladonna* and *A. blanda*). This year we shall now take up these, and, indeed, all other of our non-flowering bulbs, and shall then replant them at the proper season in the hope of inducing them to flower. It is very interesting to hear that in the Dutch bulb farms every bulb is taken out of the ground every other year at the farthest, more generally, however, every year, the "sale bulbs" being stored in the drying sheds, and the "stock bulbs" replanted in newly-trenched beds. Even in our own gardens we find that bulbs increase much faster when transplanted every year, although as a rule *Narcissi*, *Scillas*, *Snowdrops*, &c., do not bloom so well the first year after removal as they do the second. Perhaps in ordinary gardens a rotary system of replanting would be the best plan to follow.

*

ASPARAGUS FOR ORNAMENT.—Amongst the plants grown for use in our gardens as vegetables, there are some—as the Globe Artichoke, Asparagus, and some sorts of Beet—which might well be employed for ornament also. Of all useful plants, however, none lend their leafy growth with better effect when planted with Irises, Lilies, Foxgloves, Poppies, and other showy and bright coloured flowers than does the common Asparagus. Its light and feathery sprays are in reality more fresh and graceful than are those of any of the Bamboos, and some of our visitors are quite delighted with it as seen in the flower borders here and there. We use it also in a cut state along with Ferns and other greenery for relieving the bright colouring of cut blossoms of all kinds, and where flowers are cut largely for decorative purposes it will be found most useful. It is not easy to say why there should be a prejudice against the ornamental employment of useful plants, but that such does exist "goes without saying." As a friend said to me the other day, "If the Apple tree did not bear Apples, we should then grow it largely as an ornamental shrub or tree."

*

BELLFLOWERS.—Campanulas of all kinds are now coming into bloom, *C. pulla* and the forms of *C. turbinata* and *C. rotundifolia* being especially pretty as their first buds expand. *C. nobilis* var. *alba* also hangs its long white bells amongst its dark

green leaves. We raise a great many plants of *Campanula pyramidalis* from seeds, because they grow and bloom so well on our deep, rich borders, and because they do well under partial tree shade. Now and then we obtain some curious varieties. One last year assumed a dense, rounded, bush-like form only 18 inches to 2 feet in height, and was completely studded with lilac flowers, much more saucer-shaped than those of the type. Another bore white flowers, the tips of the corolla segments being united, as in *Phyteuma*. This year there promises to be more variety than ever, judging by the habits and leafage of the plants. One plant is beautifully clouded with gold—a really good, hardy foliage plant it would make if we can perpetuate it from root cuttings or seeds. Another is splashed with silvery variegation, and others have long, narrow, serrated leaves, quite distinct from those usually produced by this species, which are heart-shaped. Although we did not ourselves hybridise, it seems quite probable that our friends the bees have helped us in this matter.

*

BIG LEAVES.—Now that there is a growing taste for variety and handsome foliage in most good gardens, it surprises us to note how very rarely the Dutchman's Pipe (*Aristolochia Sipho*) is planted. As a trellis plant or for covering a fence or dead shrub with handsome heart-shaped foliage nothing could be finer than this plant, which is perfectly hardy, and succeeds well in nearly all soils and aspects. Once well planted it may be left pretty much alone, and will well repay its introduction to any garden wherein hardy foliage plants are admired. Another species, *A. tomentosa*, has smaller leaves of a paler green tint, but is equally desirable.

*

THE JAPANESE, OR RAMANAS ROSE.—Of all single Roses in flower, this is just now the best and the sweetest. It is distinct and beautiful alike in leafage and in blossom. Planted in good deep rich soil, it spreads rapidly, throwing up strong sucker shoots from its underground stems, and these flower freely all the summer months, and the flowers are succeeded by large oblate fruits or hips, quite an inch in diameter, and of a bright glossy lacquer-like red colour when ripe. Its deep green leaves, netted like those of *Salix reticulata*, are much used by our lady friends to wear with the half-opened buds of China, Banksian, Tea, and other Roses, or with the rich deep rosy buds of this Japan Rose itself. Cut in the bud state, its flowers open out fresh and fair in water, and possess a singularly rich and piquant attar-like perfume. The snow-white variety is not quite so common, but is, if possible, even more beautiful. I am sorry to hear that when the white variety is obtained, it reverts to the red type sometimes ere it blooms.

*

DAY LILIES.—If someone could raise a real yellow-flowered *Amaryllis*, what a furore there would be, and yet *Hemerocallis flava* is practically a golden *Amaryllis*, and one of the most lovely in form and colour of all hardy flowers. It grows and increases rapidly in all good soils, forming a tuft of broad grassy leaves, from which spring the elegantly curving spikes 2 feet or so in height, and these produce golden green buds and pure yellow Lily-like flowers in succession for some time. Here they grow rampant, and flower freely in full sunshine as well as beneath tree shade, where they show to the best advantage grouped along with *Ferulas*, *Oreocoma flicina*, Plantain Lilies, *Thalictrums*, *Cimicifugas*, *Pæonies*, and other foliage and flowering plants of similar habit. The flowers of all the Day Lilies are useful for cutting, but none are so fine as this *H. flava*, which bears comparison with any bothouse productions whatever. What pure and noble colour lies stored within those sombre growths we call bulbs. Seeing the glow of colour produced by broad masses—whole fields indeed—of *Hyacinthus*, *Narcissi*, *Irises*, *Tulips*, *Anemones*, and other flowers, need we wonder at the marvellous colour-beauty of the painters of the Dutch school? Holland is flat, but

not a dull land; some of her colour-effects are the purest and most vivid in the world.

VERONICA.

ORCHIDS.

Dendrobium cucumerinum is a curious little plant with leaves like tiny Gherkins and rather dense racemes of white and brown flowers. The curious character of the leaves alone is sufficient to recommend this small Australian to curiosity-mongers, and the not unhandsome flowers should tell equally in the same quarters. There is a good specimen of this *Dendrobium* now nicely in flower in the cool Orchid house at Kew.—B.

Odontoglossum vexillarium Cobbiana.—A flower of this lovely variety has been sent to us by Mr. Law Schofield, New Hall Hey, Rawtenshall, near Manchester. The flower is remarkable for the soft whiteness of the sepals and petals and the distinct pencillings of violet-purple which radiate from the centre. The column, also, is a violet-purple, a beautiful contrast to the golden crest. Mr. Schofield says he believes that there is only Mr. Cobb's plant of this and his known.

Epidendrum falcatum.—In the Orchid house at Kew there is an unusually fine variety of this well-known plant bearing several blooms. In the type the flowers are greenish yellow, with the exception of the labellum, which is cream-coloured or sometimes almost pure white. In the variety at Kew, however, the sepals and petals are white with a tint of rose, almost twice as wide as in the old form, and much more regular than in any flowers we have hitherto seen; the lip, too, is much finer than it is in typical *falcatum*. In most places so distinct a form would no doubt be thought worthy of a specific name, and indeed it has a much greater claim to such distinction than many of the Orchids one hears of as new species now-a-days. At Kew, however, the mania for new species is evidently looked on with disfavour, and it is to be hoped that before long someone there or elsewhere will take in hand the Orchid family and reduce the myriads of names attached to it to something like proper order.

Broughtonia sanguinea.—The cultivation of this plant, to a fine specimen of which in the Kew collection attention was called in THE GARDEN (p. 574), is not of any particular kind, so far at least as the method pursued in regard to the management of this handsome Orchid at Kew is concerned. As is the case with many of the smaller epiphytal Orchids from the West Indies, the *Broughtonia* thrives best when imported attached to a portion of the wood on which it is found growing, so that on its arrival here all that is required is to hang it up near the glass in a warm house and see that it is dipped frequently during its growing period. On the completion of growth a drier atmosphere is necessary for the proper ripening of the bulbs, without which no flowers need be expected. So far as my experience goes, this Orchid, along with such as *Ionopsis*, *Burlingtonia*, &c., is very impatient of any attempt at cultivation in peat or Sphagnum; indeed they often dwindle away even when attached to prepared blocks of wood. Such plants are best left alone if one gets them attached to anything on which they grew before being collected.—W.

SHORT NOTES.—ORCHIDS.

Serapias neglecta.—This is a rarely seen terrestrial Orchid. It is something like the better-known *S. lingua*, but the lip is longer and tongue-like, and of a deep elaret colour. We cannot say if it is hardy. Flowers of it have been sent to us by the New Plant and Bulb Company, Colchester.

Cologyne flavida, a pretty little botanical curiosity, is now in flower at Kew. It has dense spikes of small flowers of a soft yellow colour. The smallness of the flowers of this species serves to show the great variation in size that exists between it and the larger species, such as the common *C. cristata*.

Cattleya Sanderiana.—Of this Orchid, two very fine flowers have reached us from Dr. Paterson, Fernfield, Bridge of Allan, who says, "The blooms were cut from plants imported by Mr. Sander last year; the one a good variety, the other the finest *Cattleya* flower I ever saw." The good variety alluded to is indeed a fine one; the flowers measure just 9 inches across, by $3\frac{1}{2}$ inches in width; the labellum is 3 inches broad, and of a charming deep amethyst, with a golden yellow throat, the frilling being pink. The sepals and petals are pale lilac. This is indeed a magnificent Orchid.

Stanhopea gibbosa.—This remarkable Orchid, one of the largest flowered in cultivation, has been in flower during the past week in Mr. Peacock's collection, Sudbury House, Hammer-smith. The flowers measured 7 inches by 5 inches, the sepals being more than 2 inches in width. The colour is a creamy white, the sepals heavily blotched with purple-brown, and the petals marked with a deeper shade of brown. The conformation of the other parts of the flower is very singular, reminding one of the head of some animal. Mr. Peacock possesses an uncommonly rich collection of *Stanhopeas*, grown chiefly in suspended baskets, in order to allow the flowers to escape through their sides and bottom.

A new *Masdevallia*, recently named by Professor Reichenbach M. Carderi, is now in flower in Messrs. Shuttleworth and Carder's nursery, Park Road, Clapham, to which it has been introduced from South America. In habit and growth it resembles *M. Chimara*, but the flowers more resemble those of *M. Houtteana*. As in this species, they are triangular-shaped, and the sepals are prolonged into attenuated tails, which are yellow, minutely spotted with purple. The other parts of the sepals are ivory-white, and also, speckled and blotched. It is a singular and interesting species, and remarkably floriferous. It is named in compliment to Mr. Carder, who recently discovered it.

Odontoglossum vexillarium roseum.—I have two plants of this lovely Orchid in flower one with seven spikes and fifty-eight blooms, measuring $4\frac{1}{2}$ inches deep, one spike carrying ten blooms, the other with eight spikes and fifty-four blooms. The plants are grown in 7-inch pots, potted in peat, Sphagnum, and charcoal, with plenty of drainage and well elevated above the rim of the pots. After flowering they are turned out of the pots, washed, and repotted, and grown in an intermediate Orchid house until growth is completed, when they are placed in a lower temperature. I find that *Odontoglossum Roezli* and *O. album* succeed well under the same treatment. What has become of all the fine specimens of *O. vexillarium* which were exhibited a few years ago?—A. EVANS, *Lythe Hill, Haslemere*.

* With this note came a flower of a very fine variety of *O. vexillarium* of a beautiful deep rose tint.—[ED.]

The Marsh Orchis.—I send a few plants of the true Marsh Orchis (*O. latifolia*) and of *O. maculata* so often mixed up and confounded by botanists. Why they should be so is a puzzle to me, as no two British Orchises are more dissimilar either in foliage or flower. The leaves of the Marsh Orchis are, when spotted, like those of *O. maculata*, but of a bright and pleasant green, always erect and clasping the stem. The plant rarely exceeds 12 inches in height, and has a dense cylindrical flower of a flesh or port wine colour. It is usually found in wet, marshy ground, growing amongst Rushes and other semi-aquatic herbage, and occurs plentifully in this country, so that we have had ample opportunity for studying it under different circumstances as regards soil and situation. Miss Hope's plant (*O. maculata superba*) I have frequently found in company with the Marsh Orchis, never otherwise, and growing under similar conditions. It is evidently a hybrid or sport between *O. maculata* and *O. latifolia*, partaking of the latter's strong, sturdy habit as well as stiff, erect leaves and deep colour of flower. The thickly spotted leaves and more robust habit resemble *O. maculata*. We have several plants, found

in this district, growing alongside the true Miss Hope's Orchid sent to us by the Rev. H. Harpur Crewe, and have long since pronounced the two to be identical.—A. D. WEBSTER, *Llandegui, Bangor*.

PLANTS IN FLOWER.

VIOLA COUNTESS OF KINTORE.—This is a novel and truly charming kind, and was finely shown the other day by Mr. Cannell. The flowers are large, white in ground with a big irregular blue blotch in the middle. It is robust, dwarf, and free, and should, when abundant and better known, become an universal favourite.—A. D.

DRACÆNA AUSTRALIS.—A fine flower-spike of this plant has been sent to us by Messrs. Smith & Sons, Guernsey. It is, Messrs. Smith state, one of fourteen produced on one plant about $6\frac{1}{2}$ feet in height and fully 8 feet through. The flower-stem is twiggy, and bears myriads of small white blossoms. Such a well-flowered plant must present a handsome appearance.

DASYLIRION GLAUCUM.—This Mexican plant, though common enough in gardens, is seldom met with in bloom; therefore a fine specimen of it in the Cactus house at Kew, which has developed a monster flower-spike, possesses some interest. The spike in question is so tall that panes of glass had to be taken out of the roof to allow it to extend itself. It is not yet fully developed, and will continue to be a source of attraction throughout the summer.

HELIOTROPE ROI DES NOIRS is, we think, the deepest coloured variety we have yet seen. Its dense heads of bloom are of an intensely deep purple, and their perfume also seems to be intensified compared with that of paler kinds. It is a most desirable plant to have in the conservatory at this season if only for its perfume. It is now in great beauty in the Royal Exotic Nursery, Chelsea, where we saw it a few days since.

ROMULEA ROSEA.—This pretty little Cape plant sometimes known as *Trichonema*, is quite a gem for the cool house or frame, its bright rosy purple flowers being borne very freely if the plant be grown in a cool, sunny position. At Kew in the Cape house, where one often sees these rarer Cape bulbous plants, there is a little potful of its grassy foliage and bright coloured flowers. Close by it we noticed a plant of *Zephyranthes Treatiae* in bloom.—B.

CALOCHORTUS VENUSTUS.—A charming variety of this, the Butterfly Tulip of California, comes to us from the New Plant and Bulb Company, Colchester. Its flowers are remarkable for their unusual deep purplish tinge and the conspicuous dark blotches at the bases of each bloom. The white *C. albus* or *Cyclobothra alba* has also been sent to us, and, like the preceding, is well grown, indicating that the culture of these difficultly managed plants is well understood at Colchester.

LÆLIA PURPURATA.—Of this magnificent Orchid the Hon. and Rev. J. T. Boscawen, of Lamorran, brings us a remarkably fine spike, bearing four handsome blossoms, and he tells us that he has had as many as seven on a spike—a rather uncommon occurrence. The sepals and petals are suffused with a delicate tint of rosy lilac, while the broad, beautifully formed lip is of the deepest and richest crimson—altogether a very fine variety different in many respects from the usual type.

SAXIFRAGA COTYLEDON PYRAMIDALIS.—This elegant hardy plant, commonly known as *S. nepalensis*, is finding favour everywhere seemingly for conservatory decoration; and certainly there are few prettier plants when in flower and grown as they are in nurseries and gardens about London. A well developed plant should have a spreading rosette of leaves 9 inches or more across, and from this should rise a cone-shaped spire of flowers 18 inches high. Such examples under good cultivation are not uncommon. There is no more important point in connection with its treatment than pinching out the suckers or offshoots as soon as they appear between the axils of the parent

rosette; if allowed to grow they very soon weaken the plant as well as the incipient flower-stem. In short, a rich loamy soil and careful attention to ridding the plant of its suckers are essential to the successful development of fine specimens of this Saxifrage. If required for conservatory decoration it is best to grow it in a cold frame. Nowhere about London is it better managed than in the Royal Horticultural Gardens at Chiswick, and some equally fine examples of it now adorn the show house in Messrs. Veitch's nursery at Chelsea.

BRODLEA COCCINEA, or **Crimson Satin Flower**, as this pretty Californian bulbous plant is called, is now in full flower, and we are reminded of its beauty by some fine specimens of it which have been sent to us by the New Plant and Bulb Company, Colchester. On the top of tall, wiry stalks it bears a drooping cluster of tubular blossoms an inch or so in length, and of a deep rich crimson tipped with green. It is an easy plant to grow and flower well under frame culture. The pretty *Bravoa geminiflora* has also been sent to us from Colchester.

BIGNONIA SPECIOSA is a pretty summer flowering greenhouse climber. Its blossoms, which are as usual trumpet-shaped, are of good size and of a delicate mauve, prettily pencilled with veins of a deeper hue. A large plant of it is now in bloom on the roof of the conservatory (No. 4) at Kew. It is planted out in free soil and requires no attention from one year's end to the other, except annual pruning and tying and occasional waterings. It is, moreover, little liable to be infested with insect pests—a great consideration.

CIENKOWSKIA KIRKI.—This beautiful African Gingerwort has again commenced its long flowering season in the stoves at Kew. It will be remembered we gave a coloured illustration of it last year in *THE GARDEN*, and recommended it as a first-rate stove plant. It has handsome broad leaves plentifully associated with the flowers, which are produced on stout erect stems in crowded spikes. They are very showy, being some 2 inches across, and of a delicate soft pink colour, with just a dash of golden yellow in the centre by way of contrast. We have already given the cultural treatment which this plant requires, and therefore need only reiterate that it would be an ornament to any hothouse at this season. It is to be regretted that one cannot supplant its cumbersome botanical name by one more euphonious.

PENTSTEMONS.—Two very fine *Pentstemons* now in flower in my garden are *P. ovatus* and *P. secundiflorus*. The former, from Oregon, has very handsome, broad, and glossy leaves and numerous tall spikes of rather small purple-blue flowers; the latter, a native of the Colorado Mountains, at from 8000 feet to 9000 feet altitude, has narrow foliage, but much larger flowers of a brilliant blue with a violet tinge in the throat. A plant which I raised from seed last year has seventeen flower-spikes, each thickly clothed on one side only with its beautiful flowers, which are often $1\frac{1}{2}$ inches long by three-quarters of an inch wide. The flowers are quite as richly coloured as those of the fine dwarf *P. glaber*. These three species can all be recommended as charming ornaments of the herbaceous order. Both the above were raised from seed obtained from Mr. Thompson, of Ipswich.—**ALFRED R. WALLACE**, *Godalming*.

THE ZANZIBAR WATER LILY (*Nymphaea stellata zanzibarensis*) is by far the finest of all the tropical Water Lilies, of a purple or blue colour, in flower at Kew. It is a recently introduced variety, and we believe this is the first season in which it has flowered at Kew. The flowers are much larger than those of our native Water Lily (*N. alba*) and have broader petals. The colour is a splendid purple. There are several other kinds of Water Lilies in flower at Kew, chiefly varieties of *N. stellata* and *Lotus*, the varieties *devoniensis* and *rubra* being particularly beautiful, the flowers being large and the colour a rich ruby-red. In the tropical house may also be seen in flower the North American *N. odorata*, the rare rose-coloured variety of it (*rosea*), the flowers of which exhibit

the most delicate touch of colour that we have seen in any flower. Both the rose variety and the type seem to flourish admirably in company with the tropical kinds.

IRIS JUNCEA.—There is no *Iris*, except perhaps the common *Pseudacorus*, that has such rich yellow flowers as this rare species, blossoms of which have been sent to us by Mr. Edward Wallace, from the New Plant and Bulb Company's Nursery, at Colchester. The flowers are about the same size as those of the common *Flag*, but different in form. It grows about the usual height of the Spanish *Iris*, and the leaves, as the specific name implies, are Rush-like. When sent the flower-spikes bore one expanded flower; after this faded another appeared from the spathe valves, and has lasted three days in good condition in a cool room. There are but few flowers in cultivation which possess such a clear rich yellow as that of this *Iris*.

LITTONIA KEITI.—At the last evening meeting of the Royal Horticultural Society, held at Burlington House, there were amongst the plants and flowers shown from Kew some good blooms of the pretty *L. modesta*. In the Cape house at Kew this plant has been well grown, and flowered for several years now, and in the same house this year we notice, along with the last-mentioned, a second plant named *L. Keiti*, which appears to be a very fine variety of *L. modesta*. The flowers in this newer one are quite half as large again as in *L. modesta*, and the whole plant seems stronger and freer than the older one. The tuber resembles that of *Gloriosa* or *Methonica*, and is slightly different in shape from *L. modesta*. The handsome orange-yellow, bell-shaped flowers hanging gracefully from the axils of the lance-shaped, tendril-pointed leaves, have a very pretty effect, and are specially adapted for training along a rafter or up a pillar in a cool conservatory or greenhouse.—**B.**

CAMPANULA PULLA.—We have seldom seen this charming alpine so beautifully flowered as it is now in the rock garden at Kew, where there is nearly a square yard of it, and the whole a mass of nodding purple bells. It is a veritable gem among alpine plants, and everyone who does not possess it should make its acquaintance; it is not at all fastidious under culture. It likes an open exposed place, and we are inclined to think that it has a partiality for a peaty soil, for it never flourished at Kew until it was placed in peaty soil, and, moreover, we saw in Miss Jekyll's garden at Munstead a mass of several yards square growing in an exposed part of the rock garden in sandy heath soil. When we saw this mass a few weeks ago it was developing a perfect thicket of flower buds, and by this time must be beautiful. Where it has found a congenial place this *Campanula* rapidly increases by its underground stems, which, like Couch Grass, crop up at some distance from the parent plants, but one can scarcely have too much of so beautiful a Bellflower.

ENGLISH IRISES.—Those favoured with a sight of the grand collection of cut hardy flowers staged at South Kensington on Tuesday last by Messrs. Barr & Son could not be but struck with the fact that of the many forms of English *Iris* represented, whilst there were some that deterred, by reason of their lack of beauty in colouration, others were singularly attractive, and notably as exceedingly beautiful were three kinds that won abundant admiration. The most striking of these was *La Vierge*, a grand dark blue, truly superb kind, and one of which a note should be made by all hardy plantmen. Mr. Barr mentioned that several named forms of this *Iris* were sent out by the Dutch growers, but that *La Vierge* was the best selection of the whole, although it was difficult to find that any of the rest differed from it. Still those who order should ask for it under the name given. Another beauty was *La Charmante*, and, as its name implies, it was truly a charming kind; it formed a light lavender-blue companion to the previous named kind, and a delightful contrast in colour. Of course these flowers are not blue, as the falls and other parts of the blooms have

white grounds here and there, but the shades of blue very far dominate other colours. Finally, a very beautiful and pleasing kind was seen in *Diana*, ground white, heavily flecked with purplish maroon, a very striking form dexterously dropped in between the two blues to give the benefit of contrast. There were many other varieties shown, not the least amongst them being the yellowish white *ochroleuca gigantea*, a capital kind for forcing, and shown by Mr. Ware also in his wonderful group of hardy cut flowers. Indeed, no two finer or more interesting collections of hardy flowers has perchance ever been seen at a London show than were the splendid lots shown by these two famous growers on Tuesday last.—**A. D.**

RECENT PLANT PORTRAITS.

THE June number of *Revue de l'Horticulture Belge* figures the pretty double white-flowered *Bramble* (*Rubus rosæfolius coronarius*), well adapted for pot culture in the greenhouse, but not sufficiently hardy for outdoor culture.

The May number of *Villustration Horticole* figures *CATTLEYA NOBILIOR* (double plate, No. 485), an exceedingly handsome Brazilian species, with large rosy purple flowers and a clear golden blotch on lip.

CHAMÆROPS HYSTRIX (plate 486), the Hedgehog Palm.—An ornamental, rather low-growing species from the plains of Georgia and Florida, of very slow growth, with a bristling, hairy stem. Though usually grown in the greenhouse, it will probably prove hardy wherever the *Chamærops humilis* proves to be so.

The May number of Dr. Regel's *Gartenflora* figures *SILENE VIRGINICA*, a variety with rather thin medium-sized orange-scarlet flowers, resembling those of a *Lychnis*.

LINARIA APARINOIDES var. **AUREO-PURPUREA**.—A pretty little Toadflax with a golden centre and deep orange back petals, which should be a pretty border plant.

SUSARIUM SEGETHI.—A pretty little grassy-leaved plant with creeping rhizomes and large, rather thin pale blue flowers, resembling those of a *Sisyrinchium*.

UMBILICUS LIEVENI.—A slender-leaved and apparently free-flowering variety, bearing bunches of pale pink flowers. **W. E. G.**

Sagittaria montevidensis.—This most beautiful and free-blooming stove aquatic has been for some time in flower in the old Victoria Regia house at Kew, and, being quite unknown to me, I was much struck by its beauty when there on Wednesday last. It bears spikes of large creamy white cupped flowers, with a deep maroon blotch at base of each petal. A distinct and beautiful plant.—**W. E. G.**

The National Rose Society will hold its exhibition in the Royal Horticultural Gardens, South Kensington, on Tuesday next, in the large tent. Boxes should be brought to the goods' entrance in Queen's Gate. No boxes will be admitted after half-past ten, at which hour the gates will be locked. In addition to entries in the extra and open classes, exhibitors are requested to enter only for the classes in the one division in which they intend exhibiting. No two of the *Roses* bracketed together as synonymous in the schedules may be exhibited this year on the same stand. In the case of two stands being judged to be equally deserving of the first prize, the amount of money offered for the first and second prizes will be put together and equally divided, and the winners will be considered to have taken the first and second prizes, while the next best stand will take the third prize. The same rule will hold good with equal second, third, and fourth prizes. Printed Rose labels selected by a committee of the Society, and recommended for the use of exhibitors in the place of written labels, may be obtained of Messrs. Blake & Mackenzie, School Lane, Liverpool.

THE FIRS, LEE.

In these days, when the outspreading growth of London is fast sweeping away suburban residences which for generations past have beautified the outskirts of our great metropolis, it is a pleasure to find here and there a few beautiful gardens that have escaped the hands of the relentless builder. Such spots, hemmed in as they usually are on every side by houses, are like oases in a desert, though their number is lamentably small compared with what existed in times gone by. So near London as Lee is, and in a neighbourhood fast becoming densely populated, one would hardly expect to find such a charming garden as that of Mr. Larking in the Old Road just off one of the main arteries of traffic and within six miles or so of the heart of the city. In this garden one might almost fancy oneself far away in the country, for there is nought to remind

charming variety of plants which yield flowers from early in spring till late in autumn. The material employed for these beds and all the rockeries here is the coarse kind of rock known as Kentish Rag, obtained from quarries in the neighbourhood of Maidstone. Being in irregular masses, some nature-like effects can be obtained by a skilful disposal of them. Mr. Larking seems to have the happy knack of arranging them so as to resemble what one sees in rocky districts where the rock crops out of the ground in irregular masses. In this garden these rocky beds are not placed in set ovals or circles, but in every case are made subservient to the requirements of the plants to be grown in them. They do not obtrude baldly, as in so-called rock gardens of the ordinary stamp. A large boulder is half sunk in the soil and around it are placed a

justly proud of these grand trees, as they contribute so largely to the interest and beauty of his garden. Among other large specimens of trees on the lawn is an uncommonly fine one of the June Berry (*Amelanchier Botryagium*), having a symmetrical rounded head, which in early summer is a mass of white blossom. The other tree growth consists for the most part of deciduous trees, such as Copper Beeches, Locust trees, and a very fine *Acer dasycarpum* between 60 feet and 70 feet high. There are some moderate-sized specimens of the Cedar of Lebanon, but their growth has been arrested, in common with most all other Conifers, on account of the impure atmosphere to which they are subjected consequent on their proximity to London. It is lamentable to see how these and others, once thrifty young trees,

Lawn view at The Firs, Lee, near London

one of the proximity of the great city save the din of the passing vehicles. It is in truth a lovely garden—one that might well serve as a model of what a suburban garden should be, for every part of it has been fashioned with an artistic hand. It is, moreover, thoroughly unconventional both in design and as regards its contents, quite unlike the majority of gardens about London, which as a rule suggest the idea that all of them had been turned out of one mould.

The principal charm of this garden is its simplicity. No intricate pattern of flower beds blemishes the quiet lawn, which stretches from the front of the house to the very outskirts, and there is a conspicuous absence of any attempt at petty ornamentation, such as fountains, and basins, and statuary, which so often mar otherwise pretty gardens. The lawn, though without any garish parterre, is not, however, a monotonous green flat; on the contrary, here and there

PICTURESQUE ROCKY BEDS crop up from its surface—some isolated, others collected in irregularly disposed clusters, and all planted with consummate taste with a variety of hardy and tender plants. These rocky beds yield sufficient colour to make the outlook from the house a cheerful one, and, examined closely, they reveal a

few suitable plants, which in course of time hug its sides as if they liked its companionship. The rocky banks and beds are planted with a variety of subjects, some true mountain and rock plants, others of taller growth, and in summer these are interspersed with little colonies of brightly flowered tender plants such as *Pelargoniums*, so as to brighten up, as it were, their more sombre associates. Another great charm of this garden is its

NOBLE TREES, the growth of many generations; without them it would be shorn of one of its chief elements of beauty, and the good effects resulting from its skilful design would in a great measure be lost. The largest trees are the English Elms, whose huge spreading heads tower above everything else, save a pair of prodigious Black Walnuts (*Juglans nigra*), without question among the finest specimens in this country. This Walnut forms a magnificent tree of towering height, and the boles of this pair cannot be far short of 11 ft. in girth and nearly 70 ft. high. The massive branches spring from the trunk at a sharp angle, and the smaller branches are gracefully pendulous, and carrying as they do such dense masses of long pinnate foliage, they have as light and elegant an appearance as an English Ash. Mr. Larking is

have had their luxuriance checked and now dying a slow, but certain death. There seems to be but very few Conifers that will thrive in these days near smoky towns. *Cupressus Lawsoniana* does better than most others, and there are some creditable specimens of it in this garden in the best of health. There is now, happily, such a wealth of trees and shrubs with which to embellish town gardens, that we can well dispense with Conifers, or, indeed, with any class that will only flourish thoroughly under the conditions of an unpolluted atmosphere.

THE HOUSE, a fine old building of red brick with stone facings, and with its walls draped with Magnolias and Ivy, has a pretty effect embowered midst such fine trees as those to which allusion has just been made, and from its windows may be seen one of the sweetest garden landscapes which one could desire. The whole place contains but a few acres, but it appears much larger than it really is. The lawn is not abruptly margined, but seems to melt away into interminable recesses that run into the outskirts of the place. All the surroundings which would in any way tend to mar the effect of such quietude are shut out chiefly by the large trees, but, lacking these, high banks have been thrown up, and these have been planted with trees

and shrubs, and studded picturesquely with rocks and colonies of hardy Ferns. The end of the lawn is very skilfully treated in this way, and is one of the prettiest spots in the garden. Little shady nooks and recesses have been made for the Ferns, and in these they luxuriate uncommonly well and form a charming picture. Groups of such flowers as Foxgloves give a cheerful appearance to the place, and the sunny banks are enlivened by masses of such beautiful things as Gentsians and *Campanula turbinata*, the latter being at present a sheet of purple-blue cup-like flowers. A rosery, too, in this part is a delightful feature. The bushes are not placed in beds of a set pattern, but in irregular groups so as to harmonise with the surroundings, which partake more of a choice bit of country wood scenery than a polished suburban garden.

HARDY PLANTS, alpine as well as perennials of larger growth, are appreciated and put to good use by Mr. Larking, but he has not the conventional long mixed border. He seeks rather to produce fine effects by having bold groups of the most attractive plants in some prominent position, such as the margins of shrubberies, which in some cases project boldly on to the lawn. These bends are embellished with choice shrubs and showy hardy flowers, Lilies, Larkspurs, Lupines, and such like plants, which in good sized tufts are sufficiently showy as to be seen well from the windows of the house. The mountain plants of course find a congenial home in the rocky beds, and succeed far better than when planted on such dry stony banks which too often pass under the name of rockwork. Here the plants are placed where they are expected to thrive best, the sun lovers have full exposure, and those that delight in shade have also their wants attended to. In most cases the plants form little colonies, so to speak, and they seem to thrive all the better for being in close company with their associates. In a garden like this one may find a suitable place for nearly every hardy plant, which is impossible where the design is geometrical and without retiring nooks and sheltered, shady recesses. In one of these little bays, sheltered on all sides except the south, is a thrifty group of Tiger Lilies and others, which when in flower with the green of the shrubs for a background must have a pretty effect. In another part one comes across a little gathering of choice bulbous plants, such as the newer kinds of dwarf Fritillaries, Tulips, Crocuses, in a position where they would show best in early spring. There is a little bedding out, but this is not of the usual style. In beds of simple pattern, such as ovals and circles, one may see masses of one plant. One bed is wholly filled with dwarf *Tagetes* (French Marigold), another with China Asters, another with dwarf *Ageratums*, and so on. These beds are placed so that one comes upon them unawares; hence the effect of their brightness is intensified. A commendable feature, too, is isolated specimens of some of the finer types of hardy fine foliaged plants that have been planted, such as here and there the Turkey Rhubarb (*Rheum officinale*), Giant Fennel (*Ferula gigantea*), of which there are some admirable and extremely ornamental examples, rising from the greensward.

THE WINTER GARDEN and fernery, both arranged without stages and with the plants without pots, are noteworthy features. The houses lead one from the other, and are not, as usual, contiguous to the dwelling house, but are placed at the farther end of the lawn. The fernery is particularly well arranged. The interior consists of huge masses of Kentish rag stone cunningly placed in projecting points and retiring crannies, and by a few rugged steps one may climb to the higher portions and overlook the whole. The face of these rocks gives a foothold to colonies of sporting Ferns, and seedling Begonias, and the like, while from the crevices rise the Ferns and other plants of taller growth, the whole producing an exceedingly picturesque effect. A sturdy plant of the perforated leaved *Monstera deliciosa* is doing its best to cover the whole surface of the back wall, and here and there a few noble Tree Ferns rear their stately heads of fronds above all the rest,

while such beautiful climbers as *Lasiandra macrantha* adorn the supports and cross-beams. Among the Tree Ferns are fine plants of the beautiful *Cibotium Schiedei*, *Dicksonia antarctica*, and *Cyathea medullaris*, the latter being so high as to necessitate the heightening of the roof to admit of its wide-spreading fronds to fully extend themselves. This house is kept at an average temperature of from 55° to 65°, and is an enjoyable one at all seasons. The adjoining winter garden, like the fernery, is a spacious structure, and every plant in it is either planted out or its pot is plunged in the beds, which are raised in irregular mounds and studded with masses of rock. The seasons at which this house is seen at its best is in winter and spring, when it is gay with forced shrubs, bulbous and other plants, all of which are either interspersed amongst the permanent growth of Ferns and other greenery, or form isolated masses. The roof is hung with twiners and climbers, like the fernery, and has a very pleasing appearance. The numerous other plant houses are filled with plants of either a showy or interesting character, and among them are some choice Orchids, a well grown and flowered *Vanda suavis* being just now particularly attractive, while among the choicer fine foliaged plants are the new *Dracæna Lindenii*, a plant of elegant growth with golden banded leaves, and the new *Licuala grandis*, respecting which so much has been written of late.

THE FRUIT HOUSES are of the ordinary stamp, with the exception of the Peach house, in which espalier-trained trees are placed across it. This house, which is span-roofed, faces the west, and is some 32 feet in length. In this space there are eight well developed trees, all in excellent health and carrying fair crops of fruit, both Peaches and Nectarines. This system of planting trees crosswise in a house is objected to by some, but it answers well here, and the fruits in it are even better coloured than those produced in the ordinary way. The economy as to space, too, is a great consideration, especially in a small garden, and on this account alone the plan is well worth adopting. A noticeable feature in

THE FRUIT AND KITCHEN GARDEN is a fruit enclosure, proof against the inroads of birds and children. It consists of a rectangular structure about 50 feet long by 20 feet in width and 8 feet in height, formed of strong hexagon wire netting mounted on a stout framework, fitted at one end with a door, the keys of which are kept by the proprietor and gardener. In this enclosure are Cherries, Plums, Pears, and Apples—small pyramid trees, and beneath these are choice Gooseberries, Currants, Raspberries, and the whole has a carpet of Strawberries. Of course there are not many of each in such a small area, and due regard is paid to the importance of light in not overcrowding the plants. This somewhat novel plan is well worth carrying out where birds are plentiful and where choice fruit is required. The original outlay is a considerable item, but there is not much subsequent attention required. The kitchen garden consists of various plots in different places; thereby a variety of aspects is secured, and advantage is taken of warm, sunny slopes for obtaining early vegetables and Strawberries.

W. GOLDRING.

Ornamental Ivies.—I agree with all that is said (p. 545) as to the value of Ivies for ornamental purposes, and particularly for covering north walls that it is desired to make as ornamental as possible. First, then, I must make confession of my ignorance, which is, that till a week or two ago I had no idea that there were such a number of varieties of Ivy, or that they were so diverse both as to colour, habit, and form of foliage; and, moreover, my perception of the beautiful was so dull (at all events in respect of Ivies), that I required to see a sample piece of planting before I was able to fully comprehend their value and beauty. This I have been permitted to see at the seat of Mr. Hargreaves, Maiden Erleigh, Reading. Mr. Turton, the gardener there, has used them to cover the north wall of a flower garden, and though climbers of greater use might have been used, none of greater interest or of a more novel character

could have been employed. There is but one defect, and that is, that the stronger growing kinds are intermixed with the weaker; consequently the covering is not so regular as would have been the case had the habits of the various kinds been taken into account when they were planted; but this defect apart, the wall is quite a study, and its inspection a necessity to any who, like myself, have hitherto been "Ivy ignorant," but who now wish to do penance by using Ivies for ornamental purposes.—W. W. H.

TREES AND SHRUBS.

NOTES ON RHODODENDRONS.

The display made by Rhododendrons this season has been less brilliant with me than that of last year, but fine displays biennially are quite in accordance with my experience. A very little observation will show that the shoots which are to furnish flowers for the next year begin to grow simultaneously with the expanding of the flowers, or rather before that time. Therefore it is evident that if a plant has flower-spikes on nearly every branch it will be very thinly flowered the next season, because the growth made after the flowering season is over does not as a rule get sufficiently matured to flower. In the case of small plants this is very noticeable, though less apparent in that of large plants. Amongst some of the newer sorts the individual flowers have been very large. In this respect The Queen has been very fine. In this variety the truss is very compact and prominent. Countess Cadogan, in colour a clear transparent rose, has also been good, as has also been the well-known *Everestianum*. Joseph Whitworth, a kind with dark purple flowers in large heads, is invaluable in even a very small collection, being not only distinct in colour, but in habit, and the foliage is excellent. There are a good many varieties that produce

CRIMSON FLOWERS and various shades of red, but none more conspicuous than Mrs. John Waterer, a vigorous grower and flowerer. There are varieties of better habit for single specimens, but I know of none that has a more telling effect. Brayanum is an old variety, but very showy in a mixed bed, its colour being a vivid crimson. Amongst rose-coloured flowers Lady Eleanor Cathcart and Concessum roseum are still surpassed by recent introductions; they have both the merit of being good growers and free bloomers. Although I have already mentioned The Queen as an excellent sort, other white varieties must not be overlooked. We find Minnie particularly valuable sort; in our strong loamy soil it produces a fine display of flowers every year. *Verschaffeltii* is nearly white, but so spotted that it is always distinguishable from all others; it is also a vigorous grower. There is yet another class of flowers that are desirable in all large collections. I allude to those that have the edges of the petals barred and flamed with another colour distinct from that of the body of the petals. Of these the most notable is Princess Mary of Cambridge, a white kind edged with rosy purple and very attractive; *Bylsianum*, also white, tipped with bright crimson, a very striking flower; and Duchess of Sutherland, with a margin of lilac. These margined flowers are very attractive, but perhaps less striking than those that are nearly self-coloured. Nevertheless, they are useful in the way of affording variety.

OF DOUBLE RHODODENDRONS, I know of none perfect. In our collection we have only one, and that is semi-double. We had it under the name of *fastuosum* fl.-pl. Its colour is bright lilac, and we like it for the sake of the variety which it makes; but its greatest merit is that it is a hardy, vigorous grower. It is a fine-weather flower, a little rain spoiling its beauty and causing the flowers to drop quickly. In the matter of

CULTIVATION we have this season seen the full benefits of a system of planting which I have for some years advocated. In making fresh beds of Rhododendrons I could never see the necessity of filling them entirely in the first place with expen-

s've kinds so thickly as to make the beds presentable directly after planting. I do not say that I like to see large open spaces between the plants. What I want to say is that it is not necessary to fill up the spaces at once with the best sorts. I therefore selected a sufficient number of plants of the best varieties, and planted them 6 feet apart every way, and the spaces between them I filled up with the common ponticum variety. As the permanent plants required space, the common sorts were removed; and, although this particular plantation was only made six years ago last autumn, the plants intended to remain there have quite filled up the space allotted to them. By adopting this plan, when a fresh plantation is made it gives no further trouble beyond taking away the nursing plants. There is no need to rearrange those intended for a permanency—a great gain, for a re-arrangement means at least the loss of one season's flowers upon all plants removed. In the management of established plants there is not much to be said. In the majority of cases they are well able to take care of themselves. In our strong loam we have no need to water. In very dry summers we have had occasionally to mulch a few single plants that occupy a rather dry position; but where the beds are on level ground they succeed without any attention in that way; but not so in all cases, because I have known instances where losses through drought in the early autumn months have been serious in the case of large plants; this, however, generally occurs in shallow soils. There are some which in their natural state have 10 inches or 12 inches favourable to the growth of the Rhododendrons, but which below that are unsuitable; consequently the roots only penetrate as far as the good soil goes, and suffer from want of moisture in dry seasons. According to my experience, Rhododendrons are safe until the month of August; then, if the weather should be dry, a good soaking of water twice a week and a mulch of half rotten manure 3 inches or 4 inches in thickness are necessary in order to maintain the plants in health. J. C. C.

STANDARD RHODODENDRONS.

MANY plants are grown as standards which, from their stiff, upright habit, are totally unsuited for the purpose; but this objection cannot be urged against Rhododendrons if a selection of sorts of suitable habit be made. They are among the choicest of garden shrubs, and, when once obtained, their training and culture should be carefully attended to. When received from the nursery they always have a good ball of peat around their roots; but in many places they have to put up with a less suitable root medium. That Rhododendrons will thrive in some loams is well known, but, in cases where this has not been proved, it is not wise to risk them in anything but peat. Where the soil is of a retentive character, holes should be dug out at least 3 feet deep, and proportionate in width, according to the size of the plant and ball intended to occupy them. A foot depth of drainage should be placed in the bottom of the hole; this should be covered with the rougher parts of the peat, and over this should be placed another layer, ramming the whole down firmly before putting the plant in position. If the plants are intended to stand isolated, or in groups on the turf, they will look the better for being slightly raised above the ordinary level, leaving a small space round the stems of the plants to act as a receptacle for water. In planting, the peat should be rammed firmly about the roots; at whatever season of the year the planting may be done, they should be thoroughly soaked at the roots; and if they are to flourish unchecked afterwards, they should not be allowed to feel the effects of drought, more especially during their flowering and growing season. When once established, a little attention to training will in time make them very handsome plants. The object of training is to get rid of, or rather to hide the stem. To this end the outer branches should be very slightly depressed during the first season, bringing them down a little lower each succeeding season,

till the tips of the outer branches nearly touch the ground.

Should any strong branches take the lead in the top parts of the specimen these must be checked early. When the plants attain a large size it is advisable to run some stout tar cord through the main branches to prevent the wind from splitting them. A few strands of this cord, looped so that one branch supports another, will keep them safe from high winds. We have several dozens of these plants scattered through the grounds, some of them in very unsuitable positions, or at least where they give considerable trouble to keep them in perfect health. The greatest difficulty is where they are planted near large Elms and other free-rooting forest trees. In these cases we make a practice of trenching round them every other season, and watering copiously during the summer. As a rule, these plants are easily renovated when they show signs of exhaustion. In cases of this sort we open out a trench about 2 feet wide and 2 feet from the stem of the plant, when the ball of peat is carefully shaved all round with a sharp spade or old scythe blade. At the same time the ball is freely pierced with a sharp-pointed iron prong. After this a foot wide of fresh peat is added to each specimen operated on, and the result is always renewed health and vigour. Sometimes these plants get one-sided, and the best part of the plant faces a point where it is least seen. When this occurs they should be turned, as it is always safe to move them at almost any season of the year, provided they are well watered at the root.

The following are kinds that make good standards, being of pendulous habit: Blyssanum, Barclayanum, geranioides, Elfrida, Mrs. John Waterer, The Gem, Lady Eleanor Cathcart, Leopardi, John Waterer, Everestianum, gloriosum, Blandyanum, concessum, Cunninghami, atrosanguineum, multi-maculatum. The last-named is a small-flowered kind, and one likely to go out of cultivation before long, but it is one of the best in habit for forming standards. It is small and dense in growth and very free, and some standards of it here are the handsomest plants we have. Some of the erect-growing kinds are very useful when worked on tall stems for forming the background to large clumps of these plants. J. R. G.

NOTES ON SHRUBS.

AZALEA GLAUCA.—This is especially valuable, owing to the late season at which it flowers; its blooms, indeed, do not expand till after the beauty of Azalea pontica and its varieties is over. A. glauca is compact in habit, has glaucous foliage, and bears clusters of pure white flowers in great profusion.

ZENOBIA SPECIOSA and its mealy-leaved variety are both in bloom at the present time, and its large nodding bells are also readily produced in heat in spring, when they form pretty objects in the conservatory. When grown under glass the foliage of *pulverulenta* is even more hoary than in the open air, and its flowers larger.

PERNETTYA MUCRONATA is now a mass of tiny white flowers, which contrast admirably with its neat deep green foliage. Although the fruit is generally regarded as the most ornamental part of this plant, when in blossom it is also very handsome.

CRATEGUS PARVIFOLIA.—The flowering season of the Thorns is extended to quite the middle of June by the Tansy-leaved kind (*Crategus tanacetifolia*), Cockspur Thorn (*C. Crus-galli*), and the subject of this note (*C. parvifolia*). This latter forms a bush about a yard high; it has ovate leaves and large solitary flowers, with which it is thickly studded. In some specimens of it the flowers are nearly an inch in diameter; their large size and the dwarf habit of the plant render this *Crategus* distinct from all the others; indeed, it more resembles a dwarf form of *Mespilus grandiflora* than a Hawthorn. It has long been known in England, but is seldom seen in gardens.

COTONEASTERS, such as *buxifolia* and *rotundifolia*, have quite an interesting appearance just

now, owing to the myriads of little white flowers with which they are furnished. The berries that succeed them are also very pretty, but these plants are worth a place in the garden for their foliage alone. On rockwork or sloping banks these *Cotoneasters* are very valuable.

DIERVILLA TRIFIDA.—Weigelas, to which this shrub is nearly allied, seem to have almost driven it from our gardens, as except in botanical collections it is seldom or never met with, although both interesting and pretty—interesting from being the American representative of the Weigela, and pretty from the numbers of small yellow flowers which it bears.

RUBUS SPECTABILIS.—Among the different Brambles are many forms, some rambling in habit, but this is an erect sparsely branched shrub, generally very dense, owing to the profuse way in which it produces suckers. Its foliage somewhat resembles that of the common Bramble, but is nearly always composed of three leaflets, while the flowers are somewhat drooping, rather contracted, and of a pleasing purplish colour. It is a very handsome flowering shrub, as is also *R. nutkanus*, both of which are much later than the handsome *R. deliciosus*, whose large white flowers have been this season so attractive in many places. *R. nutkanus* has large Currant-like five-lobed leaves and pure white flowers about 2 inches in diameter. With me it flowers freely when not more than 3 feet high, but in good soils it grows larger.

CHIONANTHUS VIRGINICA (the Fringe Tree of the United States).—So called from the narrow strap-shaped petals giving to a raceme of its flowers the appearance of a bunch of white fringe. It is so different when in blossom from all other shrubs, and withal so pretty, that one wonders it is so rarely seen. In general aspect it may be likened to a Lilac. It is said to grow naturally in boggy places; in England, however, it does well in ordinary soil, but not where very hot and dry.

THE CAROLINA ALLSPICE (*Calycanthus floridus*) would be by many considered dull and uninteresting were it not for the delicious fragrance of its purplish blossoms, which, though not very attractive to the eye unless closely looked into, are not only quaint, but pretty. In a moderately moist spot and where slightly shaded from the full rays of the sun this Allspice will flower for nearly three months in summer.

OLEARIA OR EURYBIA HAASTII.—With this antipodean shrubby composite we are already familiar, but *Ozothamnus rosmarinifolius* presents to us yet another and a very desirable plant. It is a dense-growing, much branched shrub, with small Rosemary-like leaves, and bears tiny white flowers in such numbers as to almost hide the foliage. This *Ozothamnus* appears to be about as hardy as *Olearia Haasti*, and, like it, is very serviceable where small-growing, free-flowering shrubs are required.

SPIREAS.—Some of the Spiraeas are very useful shrubs where the situation is not too hot and dry; when that is so, they get stunted in growth and flower but sparingly. The following would be a good representative half dozen, viz.: *S. Douglasi*, an erect-growing species, reaching a height of about 6 feet, and bearing dense terminal spikes of pretty pink flowers. This *Spiraea* throws up suckers freely, and in a suitable spot soon forms a large mass. *S. arifolia* is a large shrub 8 feet or 10 feet high, and bears light plumelike panicles of white flowers, which are freely produced in summer. A large plant of this kind when in flower forms a striking object. Of *S. hypericifolia* there are great numbers of varieties, some much inferior to others; but if one of the best is obtained it forms, when in blossom, a grand bush. It is a slender-growing kind, and throws out long arching shoots, which are studded throughout the greater part of their length with flowers. They are arranged in clusters on small lateral shoots, and are pure white in colour. *S. callosa* forms a large clump some 6 feet high, and bears deep rose-coloured flowers in large open corymbs. The bright red hue of the young leaves also adds to the beauty of this *Spiraea*. *S. nutans*

or cuneata, though an erect shrub in the main, has drooping branchlets, and bears clusters of white or pinkish blossoms; it is a free-growing kind, and has a very graceful outline. *S. Lindleyana* has pinnate leaves, and is very distinct from all the others just mentioned; its season of flowering, too, is much later than that of any of them. In good soil this *Spiraea* reaches a height of 7 feet or 8 feet, and soon forms a large mass. The flowers are white, and borne in large terminal panicles towards the end of the summer. Even when not in bloom this *Spiraea* is very handsome.

ETONYMUSES in sheltered places are very ornamental and well worthy of cultivation. Of japonicus there are two distinct golden forms, one being rounder in the leaf and more yellow than the other; then, with the broad white variegated kind (*latifolius albus*) and one with yellowish green variegation a good variety is obtained. The Box-like *E. microphyllus* is about as hardy as the others. One that seems proof against ordinary frost is *E. radicans* and its variegated variety, neither of which have been injured in that way as far as I am aware, and both of them are, from their spreading habit, well adapted for rockwork, on raised banks, or similar positions. Besides this, they may be employed to cover walls, which they will do thoroughly, and, except a little support at first, will scarcely require any attention, as aerial roots are produced, just as in the case of Ivy, which take a firm hold of the bricks and support the plant. When in this condition, after a height of 6 feet or 8 feet has been obtained, shoots are often produced from the upper portion, partaking less of the rambling character and with much larger leaves—indeed, quite different in appearance from the foliage below.

HOLLIES afford plenty of variety, there being green-leaved, white, and yellow variegated, and one (Moonlight) in which the surface of the leaf is suffused with gold. Some, again, are densely spiny, some without spines, and others with broad, massive foliage. The Hedgehog Holly, so called from its contracted leaf, the whole of the upper surface of which is studded with spines, is very curious, and it is also represented among the variegated leaved kinds. *Ilex cornuta* has very distinct foliage, and is of dense, compact growth. A miniature shrub is *Ilex crenata*, the leaves of which are lanceolate, about 1 inch in length, and terminated by a sharp point. Its growth is dwarf, and when about a foot high it forms a pretty, neat-looking shrub. There is a variety in which the leaves are marbled with yellow, a variegation which in the sunshine is very bright and effective.

ALPHA.

5022.—**Dying Cedar tree.**—As the Cedar in question stands on a mound 4 feet high and 40 feet in circumference, and the roots are forcing their way above ground, which was cut away thirty years ago in the course of levelling the lawn, thus leaving the Cedar in an elevated position, I am strongly of opinion that it is suffering from want of proper nourishment. The roots that are forcing their way to the surface should be covered over with a thick coat of rich earth or road scrapings; of these ten or twelve cart-loads would not be too much for a tree of the size named. From its position on a mound on chalk I take it for granted that the drainage is perfect.—J. B. WEBSTER.

—No doubt the Cedar above alluded to is sending its roots upwards for nourishment which it cannot get out of the chalk. It is said to stand close to a road. Am I to understand that there is constant road traffic over a certain portion of its roots, or do they not extend beyond the side of the road where there is no traffic? If the former, you cannot deal with that side of the roots at all; but if the latter, you must hack the surface without injuring the roots, then put on about 12 inches in depth of rotten manure about 8 feet from the bole of the tree all round, and on the top of that put about 2 feet of good soil, taking care that neither the manure nor the soil touches the bark; you should then water well with the rose on the

watering-pot and gently, so that the water sinks into the disturbed surface below the manure. Give a dozen pots at least, and repeat this constantly during the summer. When the soil is placed on the manure (or before if you choose, as it is immaterial) send a man up the tree with a sharp pruning knife and cut off every dead branch and every branch in a state of decadence. I may here remark, too, that evergreens of the Pine tribe ought always to have dead wood cut out each year, and deciduous trees as well, and in the case of the latter the limbs should be pruned about 12 inches within vitality, not where it begins. As to the Cedar, place single bricks on their sides round the bole to prevent the manure and soil touching the bark. I ought to add that if the surface, when hacked over, will admit of being dug to 6 inches or more in depth without injuring the roots this should be done; the soil should be removed and the manure introduced, and on the top of that the soil must be replaced, and more soil to the depth of 2 feet, as just stated. Where this is done the mound can be sodded, and well watered continually from this time to the end of October.—J. SAUREZ COOKSON, *Neasham Hall, Darlington.*

Trees and shrubs are making a wonderful growth this season. I do not think I ever saw woods, coppices, and hedges so laden with healthy foliage—such a contrast to last year at this time, when the Oaks were almost denuded of leaves by caterpillars. I think the wet seasons in autumn and winter must have drowned or destroyed the bulk of insects and their larvæ, for there are hardly any on the forest trees this year. Gooseberry caterpillars are also scarce. Potatoes are looking uncommonly well, especially Scotch Champions. We are using old tubers of these now, and they are as white as flour and of good flavour. It was the best cropper last year, and bids fair to be the same this. It is now the best cottager's Potato.—G. B.

NOTES AND READINGS.

THE SCOTTISH HORTICULTURAL ASSOCIATION'S annual report for 1882-83, just issued, contains some interesting papers, amongst which perhaps the most valuable as well as the most practical is that by Mr. Macadam, on the analysis of soils from vineries where the Vines are known to be a failure, and from others where they have done well, the results of the analyses going to show that the failure resulted from a deficiency of potassic and calcic oxides and phosphoric anhydride, these elements being present in fractional quantities compared with the quantities in soils in which good crops are grown, thus revealing what Grape growers have all along guessed at in a rough way and acted on in practice by adding lime and potash to their Vine borders. There are soils that are deficient in both, and to these they must be given; but in many soils lime is not needed, hence the general formula of so much lime scraps to so many loads of loam from the pasture may often be disregarded. There are, however, greater mysteries in soils in their relation to plant growth than the chemist reveals to us, otherwise fruit growers would not fail to grow crops in composts made up from the recipe of the chemist, who have for years succeeded with soils selected almost at random. Nothing is more remarkable in garden practice than the different results the same men obtain in different situations. One exemplary fact connected with the Scottish Association is that it manages to live (and do a good deal of work) within its income.

MORE CARNIVOROUS PLANTS.—I notice the list of these is being extended. At the last scientific meeting another subject was introduced that ensnared the helpless insects by violating a great principle and leading them into temptation by means of honey glands. Clearly the idea of catching ants and other vermin by smearing treacle in their haunts has been borrowed from the *Cyclobothra*, which is not by any means the only

carnivorous plant of its kind. Many of our fine tricolor Heaths, for example, must be voracious midge eaters; their waxy tubes may often be seen covered all over with these insects, and no possible excuse can be assigned for the sticky matter on the flowers, except it be the latter's craving for a flesh diet. We have all but come to the conclusion, also, that the Alnwick Seedling Grape shows an inclination in the same direction—that inexplicable glutinous knob on the stigma of its flowers, showing a decidedly omnivorous tendency towards attracting stray objects, including insects, and keeping them or "absorbing" them. We opine that many of these examples of carnivorous absorption have about as much significance as a drowned rat in a water tank.

MARKET FRUITS.—Just so, Mr. Gilbert! Any rubbish will do for market purposes if it looks well and keeps well. Hard, poisonous Peaches, that can neither be eaten nor bruised, the worst kinds of Grapes badly ripened, and big Strawberries if they are just red and look well in the basket—these are the kinds of fruits that adorn the dessert tables of those who rely on the market for their supply, but they are not the kind of samples that find their way to the dinner tables of West-end mansions, where good fruit is both known and appreciated. The quality of market fruits will always afford a good reason for people growing their own fruits of certain kinds, for they cannot get them so good as at home. As for the ordinary public who buy their fruit, few of them are judges of quality. Quite the cheapest and best, as well as the most wholesome, fruit in the market up till now has been the Orange, which as it is going out of season becomes delicious; in May and June it ranks next to the Peach.

PINKS AND SPIRÆAS.—It is useful and interesting to note the prettiest of hardy plants in their season. The showiest subjects now are undoubtedly the common Rock Pinks, of which the prevailing colours are white and pink. Their profusion of flower is something wonderful, and what masses the plants make in a short time! For display they completely eclipse the other members of the family, and they last long in flower too, and have the true Pink or Clove fragrance. The curious spiral manner which the flowers have of unfolding their petals, leaving a whorl in the centre, is pretty and interesting, and has all but become lost in the demoralised Pink of the florist through long hereditary acquaintance with the tweezers. They have also the unpardonable fault of splitting their calyx, which no well-bred florist Pink does when it is bandaged in time. These Pinks lend a very gay aspect to borders at this season if used plentifully. Indeed, all the intermediate colours do. Strong and decided colours and contrasts are striking, but intermediates are most pleasing; hence the pinks and the mauves, and light blues, like the Forget-me-not, the *Viola cornuta*, and the Wood Hyacinth, are all pronounced lovely, and are permissible in large breadths where a lightsome effect is an object, a fact which should not be lost sight of in flower garden arrangements. At this season, too, the fair rosy-tinted *Spiraea palmata* is about at its best and has a pleasing effect. What a robust grower it is in cool soils in the north.

LESSONS FROM NATURE.—Those fruit-growers who believe in what they call "practical lessons" may study the habits of their Apple and Pear trees at this season with advantage. The more they do this the more they will wonder what kind of interpreter of Nature's purposes invented a pinched and pruned pyramid which no man has ever yet been able to make out a case for that you could not upset by one logical remark. By universal consent a formally clipped or pruned tree is the reverse of ornamental, while it hinders instead of promotes fertility in standard trees or bushes; therefore such abortions are useless. Trees on the Quince stock show at any time exactly what is wanted in a stock or root treatment that will keep down over-luxuriance and promote balance. To do this the knife or thumb is not

needed in any degree. Some trees, notably the *Beurré Clairgeau*, after it has been grafted a few years on the Quince, ceases to make wood shoots entirely, and produces clusters of flower-buds in excess, many of which are consequently abortive—the tree being often smothered by flowers and few of them setting. This shows too much restriction at the root, but the same thing is exhibited in all degrees in different trees, and where the stock is not restrictive enough, root-pruning or confinement at the root accomplishes the same end ten times more effectually and more easily than it can be done by restrictive top-pruning, which is a pure physiological blunder, involving a wasting of the supplies, while root restriction and unlimited top growth conserves them for use. Every leaf or branch cut away is a waste of material and force, only excusable under exceptional conditions.

STOCKS AND THEIR VALUE.—These do not differ so much as many gardeners imagine. The Quince and Paradise stocks have no special virtue in them which the natural stocks do not possess, only the former cannot pump supplies as fast as strong growing scions would appropriate them, whereas the natural stocks pump these up in excess; this is all the difference, and when the natural stock is so placed that it cannot find the supplies to pump up it is just as good as the other. This is, we believe, the philosophy of the matter. Mostly all stocks require root pruning because their feeding ground is too rich or too extensive, and the point in culture should be to curtail it by means of shallower and poorer borders, or by boxing trees in to a given space, a plan which never fails to promote fertility.

A GLUT OF ODONTOGLOSSUMS.—This is an unexpected circumstance. There have been enormous importations of *O. Alexandræ* lately, and the dealers say they are now selling cheaper than many hardy plants—as low in some cases as 7s. 6d. per dozen, which will not adequately remunerate importers; hence, as we are told, there are likely to be fewer shipments. When a plant becomes common it becomes neglected, but that is not likely to happen in the case of this popular *Odontoglossum*, the most beautiful natural wreath that can be imagined. Now that the trade has become overstocked, growers will probably begin to select, and there is need for it; for, although mostly all the true *Alexandræ*s are pretty, they vary greatly both in form and colour, some being greatly superior to others—at least growers seem to think so when nearly twenty guineas are yet asked and given for one small plant of a good variety such as we saw the other day; in fact, selection will become imperative with all species of rare Orchids that become plentiful.

PEOPLE WHO DO NOT SIGN THEIR NAMES.—I do not complain in the least of Mr. Brockbank declining to answer the questions which I put to him affecting his consistency as a florist, but his plea for not entering into controversy "with people who do not sign their names" is one which, in the interests of gardening correspondence, should not be allowed to pass. I believe I am within the mark in saying that probably the most valuable portion of the matter in gardening papers is written by those whom Mr. Brockbank declines to hold parley with, and I think I could lay my hands on proof showing that Mr. Brockbank is not above voluntarily invoking their aid occasionally when he finds it advantageous to do so. His remarks force one to say this, for they show that he is not more consistent in this matter than he is about florists' flowers. My name no more affects the question than does that of the man in the moon. To be consistent, Mr. Brockbank and others like him should not only not enter into controversy with people who do not sign their names, but they should not read their communications, a habit which, if strictly observed, would leave them in ignorance of the works of some of the most brilliant and successful writers that ever graced the pages of English literature, and whose names are unknown to this day. I may

just add that in no instance have I ever known Mr. Brockbank's ungenerous plea put forward except when the author of it had about reached the end of his tether in a controversy. Mr. Brockbank shifts his ground now when he implies that the plants at Manchester were unsuitable for the season, consisting, as he says, of *Pentstemons*, *Pæonies*, &c., which I do not recollect seeing, but I saw in the hardy collections *Tulips* which were also in bloom in the beds outdoors, *Scillas*, *Violas*, *Iberis*, *Auriculas*, *Lilies of the Valley*, *Delityras*, *Anemones*, and other spring and early summer flowering subjects, those Mr. Brockbank mentions being the exception and not the rule, while at York on the 14th of June the exhibits consisted mainly of *Pyrethrums*, *Spiræas*, *Aquilegias*, *Saxifrages*, *Pinks*, *Geraniums*, and other subjects appropriate to the season. Where, then, is the ground of your correspondent's complaint?

PEREGRINE.

INDOOR GARDEN.

SARRACENIAS AND DROSERAS.*

SARRACENIAS and *Droseras* have so much in common, from a cultivator's as well as from a scientific point of view, that I venture to link them together, as many of the remarks which apply to the one tribe also apply to the other. Beginning with *Sarracénias*, they, along with *Darlingtonia* and *Heliophora*, constitute a very distinct, though small, Order named *Sarraceniaceæ*, which comprises six species of *Sarracénia*, nearly all of which have several varieties, besides one species of *Darlingtonia*, viz., *californica*, and one species of *Heliophora*, viz., *nutans*. With the exception of the last named, these are all at present in cultivation, are similar in habit, and are natives of North America, where they are found growing mostly in bogs, and even in places covered with shallow water. Their leaves, which give them a character entirely their own, are radical, pitcher-shaped, and collected into tufts. At the flowering season they send up numerous stems, bearing each a solitary flower, the structure of which is quite as remarkable as that of the leaf. The singular aspect of the flower is due in a great measure to the umbrella-like expansion in which the style terminates. This is five-lobed, the stigmatic surface being situated at the deflexed point of each lobe. The shape of the style, or perhaps the appearance of the whole flower, caused the first English settlers in its native place to give to *Sarracénia* the name of *Side-saddle Flower*. Both in flower and leaf it is totally distinct from every other vegetable form. *S. purpurea* has been known in this country for nearly three centuries, for in Gerard's "*Herbal*" a characteristic figure is given, where it is called "*the Hollow-leaved Sea Lavender*," and is said to be copied from *Clusius*. Since Gerard's time up till 1829 all the known species have been introduced; but it is a remarkable fact that within the last ten years the number of forms has been more than doubled, and not as Gerard has written by those who "travel into foreign parts," but by those who, for the most part, stay at home, namely, the hybridists. These hybrids are so distinct, that, had their origin not been known, they would very likely have passed as species. It may be said therefore that more of these wonderful plants have been created in this country alone during the last ten years than were known to exist throughout the world. Some of them are also decided improvements on the original species as decorative plants. It is gratifying to find that their cultivation is very much on the increase, and that the beauty, singularity, and above all the wonderful adaptation in form manifest in these plants is becoming more appreciated.

SARRACENIAS MAY BE DIVIDED into two sections, viz., those having the mouths of their pitcher-shaped leaves open in consequence of the lids standing erect, thus allowing rain to enter freely, as in *S. Drummondii*, *S. flava*, *S. rubra*, and *S. pur-*

purea; and those having the lids projecting over the mouths of the pitchers, entirely preventing rain from falling into them, as in *S. variolaris* and *S. psittacina*. Their cultivation is by no means difficult. The soil should consist of fibrous peat, with the earthy matter shaken out. To this should be added from a third to a half of chopped *Sphagnum*, and a sprinkling of potsherds, charcoal, and silver sand thoroughly well mixed. This should form a free, open compost. They should be repotted annually, renewing nearly the whole of the soil. The best time for this operation is about the end of February, just before root action takes place to any extent, except in the case of *S. Drummondii*, which has the bad habit of forming abortive leaves, to prevent which repotting this species in August is recommended. They should be firmly potted, slightly raised in the centre, and the surface covered with live *Sphagnum*. They require abundance of water; to insure this place them on *Sphagnum*, which retains the moisture. This is better than putting them in flats filled with water, as the soil becomes soured and causes decay at the roots. They should be quite close to the glass, to within 2 inches from which they will be safe, and a moderate supply of air admitted. None of the species require much heat. This is an error into which many have fallen, treatment like other greenhouse plants as to temperature being sufficient. The same treatment applies to

DARLINGTONIA CALIFORNICA, a remarkable plant, found at an elevation of 5000 feet on the Sierra Nevada of California. Like *Sarracénia*, this plant has hollow inflated petioles or pitchers, but these differ in being twisted, and in widening as they reach the apex, which forms a hood. This appendage appears as if perforated at the upper part, and terminates in two fish-tail like, crimson-coloured prolongations, which give it a most curious appearance. *Sarracénia purpurea* and *Darlingtonia californica* have been grown out-of-doors in various parts of the country with more or less success. My own experience is not favourable to this method, as they make slow progress compared with those grown under glass. This may be attributed to our colder summers, which prevent the formation of well-ripened leaves, rather than to their inability to withstand our comparatively milder winters. Almost every plant has its own peculiar insect enemies, and *Sarracénias*, with all their so-called dangerous enticements to insects generally, are no exception to the rule. Green fly attack the young leaves, causing them to become deformed; and when the leaves are full grown, thrips and scale do great damage if allowed to get a hold. These must be kept in check by the usual means employed for destroying such pests. All the species are propagated by careful division, or by seed, which is occasionally obtained from strong-flowering plants by cross-fertilisation. The seeds should be sown on the surface of finely prepared soil, where they germinate readily, but are somewhat difficult to manage, being very liable to damp off, especially during the first year. In 1874, the late Dr. Moore, of Glasnevin, exhibited at the Botanical Congress at Florence the

FIRST HYBRID *SARRACÉNIA*, for which he justly received the gold medal of honour. The plant, which was in flower, is almost intermediate between its parents, *S. flava* and *S. Drummondii*, and is now known as *Sarracénia Moorei*. Soon after appeared *Sarracénia Stevni*, a cross between *S. flava* and *S. purpurea*, raised by Mr. Stevens, of Trentham. Messrs. Veitch shortly followed with their handsome *S. Chelsoni*, said to be a cross between *S. rubra* and *S. purpurea*; and last year the same enterprising firm produced the highly interesting *S. formosa*, a cross between *S. variolaris* and *S. psittacina*, and also *S. Courti*, a cross between *S. purpurea* and *S. psittacina*. Mr. Williams, of Holloway, has also a hybrid named *S. Williamsi*, the parentage of which is unknown. Last, but not least, that indefatigable horticulturist, Dr. Paterson, Bridge of Allan, has succeeded in raising a magnificent hybrid, the result of a cross between *S. purpurea* and *S. Drummondii*, and I doubt not we shall have many others ere long.

* A paper read before the Scottish Horticultural Association by Mr. Robert Lindsay, Curator Royal Botanic Garden, Edinburgh.

It seems strange that no one has yet effected a cross between *Sarracenia* and its ally *Darlingtonia*. This, which would be the most interesting of all these hybrids, has hitherto baffled all attempts. The only remaining member of the family is *Heliamphora nutans*, a native of Venezuela, which differs from the others principally in having several flowers on a scape, which are destitute of corolla; but as this plant is not in cultivation, we can only express a hope, as old Gerard did with regard to *Sarracenia purpurea*, "that those who travel into foreign parts may bring it home with them, that so we may come to a perfect knowledge thereof."

THE DROSERACEÆ OR SUNDEW FAMILY is a large one, consisting of over a hundred species of *Drosera*, three or four of *Byblis*, two of *Roridula*, and one each of *Drosophyllum*, *Dionæa*, and *Aldrovanda*. Their general cultivation is the same in nearly every respect as that recommended for *Sarracenia*, the only exception being that the soil used may be made a little less rough, with which difference they may very well be grown together. Many of them are exceedingly handsome, and all are extremely interesting. They are easily raised in quantity from seed, and also, in the case of strong-rooting kinds, such as *Drosera dichotoma* or *D. binata*, by root cuttings. If the roots are cut up into the smallest pieces and strewn over the surface of a seed-pan, covered lightly, and introduced into heat in February, keeping them close for a few weeks, almost any quantity of this elegant species can be had in a single season. As a table plant, *Drosera dichotoma*, when well grown, is very effective. The leaves, being always covered with their peculiar dewy secretion, appear, especially in gaslight, as if studded with innumerable diamonds. Other species well worth growing are *D. spatulata*, *D. capensis*, *D. lunata*, *D. filiformis*, and the three British species, *D. anglica*, *D. intermedia*, and *D. rotundifolia*. It is somewhat surprising that, out of over one hundred known species of this wonderful genus, many of which are highly ornamental, little more than a dozen are yet in cultivation. Some of the noblest forms are said to be found at the Cape, but have never been introduced. Among these are *D. cistiflora* and *D. paniculata*, having petals sometimes an inch long, with a dark spot at the base. In the same place are found two species of *Roridula*, which are shrubs—one of which, *R. dentata*, is used by the Boers in their rooms as a fly-catcher. Judging from dried specimens, these plants would well repay almost any trouble in procuring them. *Drosophyllum lusitanicum*, the Portuguese Sundew, is a very fine species, having large yellow flowers and long slender leaves, studded with innumerable secretory glands. It is easily raised from seed, which is freely produced. But perhaps the most wonderful plant of this family is

DIONÆA MUSCIPULA, or Venus's Fly-trap, a native of Carolina, and known in this country since 1765, for in that year Ellis, a well-known English naturalist, sent a drawing of it to Linneus, who gave it the poetical name of *Dionæa*. The account which Ellis gave of it moved the great Swedish botanist to declare that, though he had seen and examined no small number of plants, he had never met with so wonderful a phenomenon. Ellis having a year or two afterwards obtained living plants from America, grew and flowered it in his own rooms; and from him we learn that the insectivorous predilections of *Dionæa* have been suspected for more than a century. *Aldrovanda vesiculosa* may be called a miniature aquatic *Dionæa*. It also has bilobed sensitive leaves arranged in whorls on the stem, which capture minute aquatic insects. It is found in ponds in Italy and some parts of Germany. Unfortunately, it will always be a difficult plant to cultivate, as it is entirely destitute of roots.

5017.—*Stephanotis* not flowering.—It is difficult to say why the *Stephanotis*, in this case, refuses to flower, but probably it is either a shy blooming variety, or having plenty of root-room, is growing too freely to be floriferous. It is a well

known fact that some varieties are much more floriferous than others; indeed I have found it necessary to remove large plants in consequence of their being shy bloomers after means had been tried in vain to induce them to flower. That known as the *Elvaston* variety, for which there is now a greater demand than for the common kind, is a very free flowerer. This kind should therefore always be secured if possible. Before, however, discarding the plant in question, I should try the effect of curtailing its root-run.—H. P.

Fungi in propagating pits.—Like "W. J. T." (p. 575), I have been several times troubled with a bright yellow fungus in the propagating pits, the mycelium of which spreads with great rapidity in the Cocoa-nut refuse employed therein. In my case the yellow powder was freely distributed over all surrounding objects when the fungus reached maturity, and in most cases it led to the decay of the cuttings on which it fell, especially if of a somewhat succulent character, such as those of *Begonias* and *Fuchsias*. There are great differences in Cocoa-nut refuse as to the rate at which fungi will spread in it, but when they once take possession there is but one remedy, and that is to remove all the old refuse, and after a thorough cleansing replace it with new. The way in which I always succeed in getting rid of fungi is, after clearing out the Cocoa-nut refuse, to white-wash the walls with hot lime, and indeed every part touched by these pests. This destroys any atoms of spawn that may be left, and at the same time tends, in common with the new fibre, to purify the atmosphere of the pit or frame, so that afterwards cuttings difficult to strike are less liable to decay than before such cleaning took place. For the lime washing do not use the rather costly hair-brushes employed by plasterers, but a cheaper kind made of vegetable fibre, as the latter is not injured by the action of the lime, whereas the dearer ones will be spoilt by it.—T.

5015.—**Billbergias.**—The whole of the *Bromeliads*, without a single exception so far as I know, are sun-loving plants, many of them being epiphytal on the tops of trees and bushes, where they enjoy the intense brightness and warmth of a tropical sun for the whole day. The conditions under which these plants are found growing in the greatest abundance are chiefly in open, sunny places on the edges of forests, where heavy rains are frequent and a heavy dew is deposited nightly. I have been told by a plant collector that in the early morning the urn-like growths of *Billbergias* and other *Bromeliads* are filled with water, which by evening has evaporated, leaving the plants quite parched. To attempt to imitate Nature in every respect is not always wise, but in the case of *Bromeliads* one may do so pretty closely and be fairly successful. We grow our *Billbergias* along with a large collection of *Bromeliaceæ* in a hot, moist stove on a side stage on which the sun is permitted to shine all day. The plants are syringed heavily in the morning, and in many cases a quantity of water is always found in the growths. During summer plenty of water is supplied to the roots. The growths after flowering do not die, but they will not flower again, though they produce one or more suckers at the base, which, in the stronger kinds, are removed when large enough and grown on singly, a good plan if large growths and flowers are wanted. The yellowness of the leaves may be owing to sourness of the soil in which the plant is growing—certainly not the result of too much light. The mixture we use is one of lumpy peat and loam with a little charcoal. Manure water is given now and again during the summer months. In the case of *Billbergias* one would not go far wrong by following the instructions given for the cultivation of *Pines*.—B.

Shakespeare as an angler.—Canon Ellacombe, who contributed so many interesting articles to THE GARDEN on the plant lore and garden craft of Shakespeare (afterwards published by him in a work-bearing that name), has been following up his Shakespearian studies, and has lately issued a book on "Shakespeare as an Angler." It is published by Mr. Elliot Stock.

GARDEN FLORA.

PLATE CCCXCIV.

SISYRINCHIUM GRANDIFLORUM.*

Who would imagine that this lovely plant was as hardy as a high alpine flower and strong enough to withstand the cold rains of February or the winds of March. The plant is altogether more slender and graceful than any other open-air plant with which we are acquainted. Its Rush-like foliage, growing erect and tufty, has doubtless suggested its popular name of Rush Lily, a name which to some is easier remembered and more euphonious than that given it by botanists. When well and fully grown it is from 12 inches to 15 inches high. The flower-stems are intermingled with the foliage and are about the same height. The blossoms are usually borne in pairs produced on slender stalks drooping out of the membranous sheath called a spathe. One flower usually expands a day or so before the other, and if the stem is cut just as the first flower begins to open the second one will succeed it as if it were still on the plant. Interesting as the plant is in the open border, it seems almost a pity to leave such delicate beauty to the mercy of the weather; and as the flowers last long in perfection when cut it is best to have a few in a vase indoors where their beauty can be thoroughly enjoyed. We have said it is a hardy plant, but the term hardy is subject to conditions, for in some localities, particularly if the soil is surcharged with water in winter, it will succumb to hard frosts. In light soils it is perfectly hardy, but even under such circumstances the plant seems always grateful for a little protective mulching during winter, such as short litter or Bracken. Its normal flowering time is in April and May, but it blooms in some gardens in warm localities as early as the middle of March if the weather is sufficiently mild. The early bloom is accelerated by a good mulching of litter put round the plants in autumn, which, moreover, prevents them suffering from violent changes in the way of weather. This early bloom, however, is never so beautiful as that produced in the latter end of April and May, when the days are longer and warmer.

There are two forms of this plant, the one supposed to be the typical, distinguished by its very fine vinous-purple blossoms, the other called the album or white variety, having flowers of spotless white, save the gold-tipped tufts of stamens. It is a hard matter to say which is the more beautiful. Both are charming kinds and worthy of the attention of every flower lover. In both the petals exhibit a transparency seen in few other flowers, and certainly in no other hardy plant. The form and colour of the flowers are shown in the accompanying plate. This is not a new plant, having been introduced so far back as 1826. It is a native of that tract of country in the vicinity of the Columbia River which was explored by the botanical collector, Douglas, and it was by him it was first sent home. It was named *S. Douglasii* by Dietrich in compliment to its discoverer, but the name which Douglas gave the plant is retained on account of priority of date.

The culture of this plant is simple. It likes a good friable soil, such as may be found in most kitchen gardens. Some say it likes a shady place, but we have always seen it do best in the open in full exposure, but it is best to shelter it from

* Drawn from plants in the Hale Farm Nursery, Tottenham, in May last.

11

SISYRINCHIUM GRANDIFLORUM (L.) R. & S.

strong winds in some way, as they tear and knock the plants about so badly. To propagate it the plants should be lifted in autumn, and the tufts pulled carefully into as many pieces as are required, always leaving a sufficiency of roots on each piece to start it into growth. The pieces should be planted immediately in light soil, placing a little sand around the roots in order to induce the formation of new rootlets. Fibrous rooted plants such as this require careful handling when propagated, for the roots soon suffer. Some grow this plant well in pots for greenhouse decoration in spring, and a very pretty plant it is for the purpose. There are about ten other hardy species of *Sisyrinchium* in gardens, but singularly enough this is the only one really worth growing, though *S. anceps*, *striatum*, and *convolutum* might perhaps be tolerated in a full collection.

SEASONABLE WORK.

FLOWER GARDEN.

TOBACCO PLANTS.—Of all annuals suitable for flower borders, and for grouping in masses in the sub-tropical garden, the Tobaccos or *Nicotianas* are probably the most rapid growers and the most easily raised. They have also the additional merit of being comparatively hardy, and can be planted out earlier than any of the other kinds of plants usually classed as sub-tropical. Seeds sown on a slight hotbed in March, and the young plants potted off singly as soon as they can be handled, and given ordinary frame culture, will be large to plant out in May. The best varieties are *Tabacum* and its variegated variety and *wigandoides*. In good soil all three kinds attain a height of 8 feet, and have broad massive foliage and long spikes of pink blossoms. They flower so freely, that to prevent premature exhaustion it is necessary to reduce the flower-spikes to about a couple on each plant, as well as to prevent them from seeding, by frequently picking off the bad flowers. Under this simple culture they will retain their effectiveness till very late in autumn. If planted in groups, each plant should not be allowed a less space than 3 feet.

BEDDING PLANTS.—The change to colder weather which we have just had has made the tender section of bedding plants look wretched; so much so, that one almost regrets that there are such plants as *Coleus* and *Alternanthera*; but having used them, and that with grand effect, when the seasons were warmer, it is difficult now to make up one's mind to exclude them, but sooner or later it must come to that; meanwhile we must be on the outlook for hardy substitutes; at present the only available hardy kinds are the bronze *Ajuga* and *Oxalis corniculata rubra*, both a long distance in the rear as regards brightness of colour, but moderately effective when planted in dense masses. Though it is yet early to form an opinion as to whether or not such tender plants as the *Coleus* and *Alternanthera* will fill out their allotted space, the moment there is a doubt in the matter will be the time to set to work to cover the ground; dwarf *Sedums*, dibbled in amongst them, quickly do this, the mixture so formed being infinitely preferable to bare plots of earth. In the case of succulent arrangements keep the flowers picked off *Echeverias* and other ground-work plants associated with them, such as *Sedums* and *Saxifragas*, but the small flowers of *Mesembryanthemum cordifolium* variegatum harmonise so well with succulents, that they should be left. It will, however, be necessary to occasionally pick off the seed-pods in order to keep the plants in free growth. The most pleasing bed we have at the present time is an arrangement of large succulents, consisting of *Yuccas*, *Agaves*, and large-growing *Echeverias* and *Sempervivums*, the whole being in a setting of the large, mauve-flowered *Mesembryanthemum conspicuum*, and the only attention it has ever had or needed since planting

has been the keeping of the *Mesembryanthemum* pegged under the taller plants. In rain or sunshine, in fact in all weathers, these succulent arrangements are equally pleasing, and worthy of adoption on that ground alone, not to mention their desirability on the score of variety. Keep the under growths of sub-tropical plants neatly pegged down, and in cases in which such undergrowths have been deemed unnecessary the beds should be kept mulched with Cocoa fibre or leaf-soil. For the present the flowers should be kept picked off *Cannas*, *Castor-oils*, and the like, and all that need tying and staking should receive that attention before any injury accrues from its neglect.

GENERAL WORK.—During showery weather the weeding and rolling of walks will well repay all the labour that can be afforded in that direction. Shrubberies and mixed flower borders will also require more than ordinary attention as to the destruction of weeds, and the mowing necessary to ensure a close, velvety turf is just now incessant. Roses need washing for the destruction of blight; bad flowers should be picked off once a week, and the growths of any that have done flowering should be shortened. Daisies, Pansies, Primroses, Polyanthuses, Violas, Pinks, and other spring flowers may now be propagated by division, cuttings, or seeds; they all do best in partial shade; a border having a north or east aspect is in every way suitable. Any strong plants there may be to spare will do good autumn service in the mixed borders amongst Roses.

INDOOR PLANTS.

DOUBLE PRIMULAS.—The advantages which these possess over the single kinds where flowers for bouquets are much in demand are their greater duration when so used and their continuous habit of blooming, especially the white and distinct pink kinds, such as Gilbert's seedlings, that deserve to be grown extensively; not only are their flowers individually much larger than those of the old sorts, but the habit of the plant is more vigorous. Every attention should now be given them in the way of pot room and plenty of light, with no more shade than is required to break the sun's rays and prevent the foliage from assuming a sickly hue. If seeds of the single varieties were sown at intervals of about two months, there will be a good prospect of a continuous succession from autumn up to spring, and to have the stock in such order as will enable it to produce a full crop of flowers there must be no want of attention, especially in giving more root room as required. Plants of the last sowing should be encouraged to make growth, so as to admit of their being got into their blooming pots before the season is too far advanced to allow them to attain size enough to flower well. On no account allow the stock of either double or single kinds to stand too close together from the first, for where this occurs the leaf-stalks get drawn out weakly, a defect that cannot afterwards be remedied. The best place for Primulas in summer is in ordinary frames facing northwards at the north side of a low north wall with their heads close up to the glass. Thus situated they will get plenty of light, but not under the full force of the sun. The lights should be well tilted up back and front in the daytime, and a piece of garden netting should be put on the glass in the middle of the day when the weather is bright.

HELIOTROPES.—These must be kept close to the glass when subjected to the warmth requisite to bring them into flower during autumn and winter; consequently, where they will have to be brought on in low pits, small plants such as can be grown up from spring-struck cuttings occupying 6-inch or 8-inch pots should at once be placed in such, regularly pinching off the flowers as they appear. This is necessary in order to direct all their strength to the formation of growth. Large old *Heliotropes* are most useful where there are means of giving them the requisite room, as where these exist, if encouraged with a little warmth after the weather gets cold, they will go on blooming for

months. With large examples of this description it is not so necessary to keep all the flowers nipped off now as in the case of small ones, but means must be taken to keep them growing freely by the aid of sufficient pot room and frequent applications of manure water.

PERPETUAL FLOWERING CARNATIONS.—The later flowering stock of these will now be in fine bloom, and should be assisted with manure water once a week, which will induce them to push up strong shoots from the bottom that will flower later on. Plants that have been forced early should have their old flowering shoots well shortened back, so as to encourage the young shoots, which in free-growing varieties are always making their appearance; they should then be turned out of the pots without disturbing the balls of roots more than what occurs in removing the drainage, and be planted out in prepared soil, not too light, but with sand enough in it to admit of their being taken up and potted in the autumn without much breakage of their roots; they must have an open situation fully exposed to the sun, and not be allowed to suffer through want of water. If well managed they will produce many more flowers than younger plants, and will not be so leggy or unsightly as where the old stems are allowed to grow up without cutting back. Young plants struck from cuttings in the winter or spring must have all the attention which they require, or it is useless to expect more than a meagre production of flowers. Move them as soon as necessary out of the small pots they occupy to others a couple of sizes larger, using good strong new loam, to which has been added a little leaf-mould with some sand, but not so much as is required by most soft-wooded plants, as if the soil is too light they will not be unlikely to refuse to move altogether.

FRUIT.

PEACHES.—When all the fruit has been taken from the early house, go over the trees and remove the shoots which have performed their office and can now be spared with advantage to the young growths intended for next year's fruiting. Tie in and regulate the latter, allowing plenty of room for free development of foliage and the free admission of light and air. Syringe regularly with pure water where the foliage is clean, and add soft soap or Gishurst compound on dull evenings to keep it clear of spider. Keep the inside borders regularly supplied with water, and renovate the mulching where the trees show signs of weakness or exhaustion from heavy cropping, but carefully guard against forcing them into a vigorous growth when they should be going to rest. The ventilators may now be left open by night and day, and when the buds are well made up, the roof lights, if possible, may be taken off, painted, and stored away ready for use early in the autumn.

SUCCESSION HOUSES.—If time is an object the trees in succession houses may now be subjected to a higher temperature than would have been safe before the fruit commenced its last swelling, but it must be borne in mind that nothing in the way of quality is gained by it, increased size, colour, and flavour being the true tests of merit. We prefer a temperature ranging from 60° at night to 75° by day, with plenty of air and full exposure by drawing the lights off when the weather is very fine after the end of June. Where good soft water can be obtained the trees may be syringed every morning until the fruit has attained its full size and shows signs of changing for ripening, but on no account should the afternoon syringing be performed when there is danger of the foliage remaining wet after nightfall. If the roots are confined to internal borders, and the latter are well drained, liberal supplies of water at the mean temperature of the house will be needful in this and later houses; but where they run outside, the heavy rains we have lately had, combined with good mulching, will keep them in a satisfactory state until the earth becomes much warmer than it is at the present time.

LATE HOUSES.—See that the wood is thinly and evenly laid in in late houses and wall-cases, par-

ticularly where no heating apparatus has been provided for ripening it up in the autumn; pinch the points out of gross shoots where they are likely to rob the fruit or weaker parts of the trees, and elevate all that can be raised to the influence of sun and light as the work proceeds. Syringe well twice a day, leave the ventilators constantly open, and mulch the roots with some non-conducting material to counteract the drying influence of constant currents of air; but guard against the use of over-rich manure, which will force the trees into vigorous growth late in the season.

FIGS UNDER GLASS.—Our early forced trees are now swelling up the second crop of fruit, and a few of the most forward Figs are beginning to ripen. The fruit has been well thinned to insure good size, and the roots have been liberally supplied with warm liquid to keep the trees in growth. From the first week in June stopping is discontinued, as it is from the young growths now being made that next year's first crop will be obtained. When all the best fruit has been gathered the lights will be taken off the roof, the shoots will be well cleansed if insects are present, and the trees will be allowed to go gradually to rest. In our best house a large tree of Brown Turkey is ripening hundreds of fine Figs. This tree is planted out against a rough stone wall forming the north side of a span-roofed pit. The shoots are trained upwards to the ridge, thence downwards to the south front. The winter pruning consists in cutting away barren shoots which have reached the extremity of the trellis to make room for summer growths, and as these are never stopped, a successional growth of wood and fruit is secured until the time arrives for withholding stimulants. The shade produced by the foliage having caused the stems of eighteen years' growth to throw a complete network of roots over the surface of the old limestone wall, we keep them packed Orchard fashion in the pieces of turf, from the floor line 4 feet upwards, and feed copiously with warm liquid, which is poured on at the top every other morning, or as often as the turf roots and projecting stones show signs of becoming dry. We ought to say the wood never becomes so gross, neither does the fruit drop at the usual critical period of its growth, two striking proofs that this heat and moisture-loving tree is most decidedly at home when planted where rich, stimulating food can pass quickly away and the air is not excluded from the roots.

STRAWBERRIES IN POTS.—Young plants intended for early forcing should be placed in their fruiting pots by the end of this month or early in July. Small pots, 5 inches to 6 inches in diameter, are quite large enough for the first batch, but for the general stock a larger size may be used with advantage, if only to economise time in watering. See that the fruiting pots are clean, dry, and well crocked, for, much as the Strawberry enjoys a strong, rich soil with plenty of moisture, it soon becomes unhealthy in a pot from which water cannot pass away freely. Pot the plants singly, with the crowns well up above the soil when all is finished, and place them on a hard surface in a light, airy situation convenient to water, and, if possible, free from worms. Avoid crowding the plants together or setting them near trees, as it is important that the leaf-stalks be kept short and stout, and that good single crowns in preference to double ones be thoroughly ripened before the autumn. Water well with water which has been exposed to the atmosphere, and keep the beds of concrete or ashes on which they are placed well moistened, but avoid wetting the tender foliage in bright weather or at any time with water that is colder than the mean temperature of the air. Remove all weeds and runners. Apply lime water if worms gain a lodgment, and rearrange occasionally, as they require more room, and to prevent the plants from rooting into the ground. With many growers it is the practice to avoid the use of small pots altogether by filling the fruiting pots up to within three-quarters of an inch of the rim, and then pegging the runners tightly down on the surface. The drawback to this plan is the establishment of a colony of worms during the time

the pots are standing on the quarters, and the time occupied in watering in dry weather. The plants, however, make excellent heart buds, which ripen well, and the check which follows shifting from 3-inch pots to fruiting pots is overcome.

ORCHIDS.

EAST INDIA HOUSE.—We find *Odontoglossum Roezli* to succeed best in this house, but in the coolest end, there being a difference of at least 5° between the two ends; our plants of it are placed very near the glass, and when making growth are as freely supplied with water as the cool house species. They have just passed through the flowering period, and are again starting to grow. Some of them were repotted about mid-winter, and have done well; these will not be disturbed now, but all that were repotted at this time last year will be potted again; the roots should not be disturbed more than what may happen in removing the decayed and sour compost. For these we fill the pots with drainage up to within 3 inches of the rim. They should be cleared from thrips before repotting. Some of the *Cattleyas* grown in this house will now be pushing up their flowers from the recently formed pseudo-bulbs; amongst these we place *C. gigas*, which flowers best when placed very near the glass in the coolest end of this house. *Cattleya Dowiana* requires very similar treatment. It does well with the pots placed inside a basket. *C. superba* is grown in quite the warmest end, but this should be on a block, or, what is better, fastened to a bit of the stem of a Tree Fern. We find *Cattleya Warneri* to succeed better in this house than in a cooler temperature. Our best plant of it has been grown here for many years and always flowers well. Any *Dendrobiums* starting into growth, as many of them do at this time, should be repotted as they require it; give them plenty of heat and moisture, and occasionally syringe them overhead. The smaller-growing species should be placed near the glass; those that are taller will do in the centre or on the side stages. *Saccolabiums* are now beginning to make fresh roots; if any of them require robust setting or repotting it ought to be done at once. These Orchids dislike being disturbed, and if the potting material has become decayed, it may be best to carefully pick it out from amongst the roots and substitute fresh material. They do not require any peat amongst the Sphagnum, but crocks and charcoal are necessary to keep it open. We find it answers well to have dried Sphagnum that has been well washed previous to drying to work in amongst the roots, finishing off with live material chopped fine and that has been mixed with a little pounded charcoal as well as the lumpy portions of it. We always wash the leaves with soapy water before potting.

CATTELEYA HOUSE.—If any *Cattleyas* really require repotting, it should be done now, but we are of opinion that January is the best time for performing the operation. Most of ours are being left until that time. Recently imported plants are dealt with differently. Some pot the plants at once in the usual compost, and as a rule roots are very soon emitted from the base of the last formed pseudo-bulbs. The best way, perhaps, of treating all such plants, including *Laelias*, is to pot them in clean crocks, and as soon as the roots have begun to push, remove some of the crocks and replace them with the usual compost; the roots run into it at once, and before it becomes tainted by repeated waterings. Many new and notable additions are constantly being made to *Cattleyas*, and as there is always much pleasure in watching the development of new forms, it ought not to be forgotten that as a rule flowering sheaths are most likely to be formed when the plants are placed near the glass. We had six plants of *C. gigas* in one house placed on the stage; they were not more than 3 feet from the glass, but not a flowering growth was formed upon one of them until they were all suspended from the roof close to the glass; now they are all forming flowering sheaths. *Odontoglossum hastilabium*, an inmate of this

house, is usually much punished by the long time during which its flowers remain on it. We have have had single spikes last for three months and longer; one even lasted six months. Carefully attend to the plants in the way of giving water at the roots, and maintain a moist growing atmosphere. They are now making new growths and pushing out young roots.

COOL HOUSE.—The instructions recently given as to the general treatment of this house will do for the next two months. We have not had very hot weather, consequently no extra precautions have been necessary; indeed, the rather cool, moist atmosphere has suited the occupants of this house well. We would rather not repot many of the *Masdevallias* and *Odontoglossums* at this season, but it may be necessary to do so; in that case we are careful to disturb the roots as little as possible, and are also very careful not to let them suffer from want of water afterwards. Cool house Orchids are rapidly increasing in numbers and interest, and the house need not be altogether filled with *Odontoglossums* and *Masdevallias*; a few of the finest *Dendrobiums* may find a home there. *D. Jamesianum* and the nearly allied *D. infundibulum* make the best growths in the warmest end of the cool house; in potting and watering deal with them much the same as is done with *Odontoglossums*; they like to be near the glass. Besides *Oncidium macranthum* alluded to in last calendar, another really pretty species does best in this house, at least during the summer months, viz., *C. cheiroporum*; it is best grown in pots, but the pots may be placed in baskets and suspended from the roof. Amongst *Cattleyas* the lovely *C. citrina* succeeds well on blocks or in shallow pans. In either case it is best suspended from the roof. *Laelia majalis* and *L. autumnalis* are good subjects for this house. They will do very well if they can be placed in a corner where they can get a few hours' sun each day, as they will not form flowering growths if they are too closely shaded. Cultivators know that certain plants must be placed in the lightest part, others near the ventilators, and others again at a distance from both. To grow Orchids well in any department it is necessary that their habits and the conditions under which they are found in their native habitat should be known and, if possible, adhered to when under cultivation.

KITCHEN GARDEN.

KEEP the hoe constantly going among growing crops, and prick out Broccoli, Savoy, and winter greens. If ground for them is not likely to be early at liberty we always sow as late as possible, so that the plants do not get drawn while they stand in the seed beds. Early Potatoes now occupy the ground where we intend to plant our spring Broccoli; therefore with us pricking out the plants will be a necessity, otherwise we prefer planting from the seed bed. Keep Tomatoes well nailed to the walls. Encourage them to become strong healthy plants, so that their fruit may be a sure and profitable crop. On Globe Artichokes recent winters have left their mark, but last two winters being mild ones have helped them wonderfully. We are well watering our stock of these, and will not forget to duly protect them next winter. All Celery for late spring use should now be pricked out. Keep early Celery in the trenches growing by giving it daily a slight damping. It should be kept constantly growing.

Lathyrus Sibthorpei.—This is one of the most showy of perennial Peas, and generally blooms much earlier than June. I have grown it over fifty years, having first got it from the late Mr. Baxter, of the Oxford Physic Garden, as it was originally called. It was introduced there by the late Dr. Sibthorpe, professor of botany at Oxford. He travelled in Greece to collect rare plants, and this was one of them. It seeds freely with me, and I will be pleased to send some seeds when ripe to any who will send me a stamped envelope for the purpose.—H. T. ELLACOMBE, *Clyst St. George, Tapsams*.

STERILITY IN PLANTS.

THE following extract from a lecture by Dr. Matthew Duncan, published in *The Lancet* the other day, may not be without interest:—

Viewing this subject generally, we may anticipate a great result by pointing out the paramount prevalence and potency of constitutional conditions as causes of sterility. Such are cold and heat, overfeeding and underfeeding, youth and old age, degradation of general health, confinement, and inter-breeding. Local conditions occur in plants that are quite sufficient to account for or cause sterility. Such are contabescence of anthers, monstrous flowers, double flowers, seedless fruit. These local conditions are the result of the general or constitutional conditions of the individuals in which they occur; and they have their place rather in the results of sterility, or of the conditions producing sterility, than in the causes of sterility. In the vegetable kingdom everyone has observed that source of sterility which may be, no doubt nearly truly, designated a degradation of general health. A plant covered with flowers is brought from a house where its fertility has been stimulated to the highest degree, and placed as an ornament in a sitting-room, where it remains till its charms are lost, and the result is such an injury to its constitutional vigour that it is sterile, or nearly sterile, for one or for several subsequent seasons. Its fertility may never be restored, or only after several years of the medical care of a skilful gardener. The scarlet Geraniums which are brought from their healthy homes in full bloom to adorn the houses of inhabitants of densely populated cities soon show the injurious influence of their new surroundings, however well they may be cared for; their flowers become less numerous, or are altogether wanting; then their leafage diminishes greatly in quantity, and their existence becomes a mere lingering. A Rose garden, lately in a suburban position near London, gets surrounded by the growing city, and gradually as the buildings increase the fertility of the Roses diminishes; the garden becomes useless. Some of our finest forest trees, and among them some plants, grow beautifully in our squares, producing wood in even exaggerated quantity, and a clothing of leaves sufficient for ornament; but there is no wealth of leaves, and there is no seed. In some cases an exception makes the rule more striking, as when a Cherry tree in the heart of the City of London lately produced flowers and matured its fruit, so far as maturity is indicated by beauty, size, and taste. Practical gardeners attribute sexual injury to over-stimulation by manure, or what they call

OVER-FEEDING. This ordinarily produces great growth of the tissues; and when this is restrained by judicious pruning, it forces out a large or excessive crop of flowers and subsequent fruit. In the language of Spencer, there is produced by over-feeding an excess of individuation, the restraint of which results in excess of genesis. The natural tendency of the overfeeding of plants is to produce a degree of relative sterility; and this may show itself in paucity of flowers, or it may show itself in the production of those double, or monstrous, or abortive flowers which are so much admired. The opposite result is produced by moderate or full feeding. Then, in mature plants there is not great growth of tissues, but rather a production of fruit. Sometimes the plant, without assignable cause, but especially if underfed, has an exaggerated production, and is said to run to seed; and, from whatever it may arise, it in a reflex manner injures the plant, which consequently becomes blighted and often dies. Excessive production here seems to take the place of sterility. The following is an interesting illustration of the effect of over-feeding and of moderately feeding or under-feeding a Vine, and it is important because it specifies a particular local condition or disease which is apparently the cause of the infecundity of the over-fed plants, and so indicates a line of investigation which may with advantage be pursued in other examples of sterility. In a recent letter from Mr. Thomson, the well-known Vine cultivator, he writes: "A

circumstance has arisen in my own experience that I have never seen noticed in print. A Vine called the Alnwick Seedling, if grown vigorously in rich soil, fails to set its fruit even when aided. This failure is caused by the exudation from the female organ of a dewdrop of sap, which moistens the pollen, and it does not descend through the pistil and impregnate the ova. When the Vine is grown in poor soil the dewdrop does not appear, and impregnation takes place; seeds are formed in perfection, but the pulp for which the Grape is grown is almost absent. I know" (he adds) "no other Grape affected in the same way or subject to the same influences." I know no good account of the

STERILITY OF PLANTS AS REGULATED BY AGE, but the influence of age is well recognised. A young fruit tree bears no fruit, or very little, and that little imperfect, and the careful gardener does not permit it to bear much or even a little, believing that fruit bearing injures growth and diminishes future fertility. The influence of old age in fruit trees is also well known: the fruit is ill developed, and there is little of it. "All know," says Spencer, "that a Pear tree increases in size for years before it begins to bear, and that, producing but few Pears at first, it is long before it fruits abundantly. A young Mulberry, branching out luxuriantly season after season, but covered with nothing but leaves, at length blossoms sparingly, and sets some small and imperfect berries, which it drops while they are green; and it makes these futile attempts time after time before it succeeds in ripening any seeds. But these multiaxial plants, or aggregates of individuals, some of which continue to grow, while others become arrested and transformed into seed-bearers, show us the relation less definitely than certain plants that are substantially, if not literally, uniaxial. Of these the Cocoa-nut may be instanced. For some years it goes on shooting up without making any sign of becoming fertile. About the sixth year it flowers, but the flowers wither without result. In the seventh year it flowers and produces a few nuts, but these prove abortive, and drop. In the eighth year it ripens a moderate number of nuts, and afterwards increases the number, until, in the tenth year, it comes into full bearing. Meanwhile, from the time of its first flowering, its growth begins to diminish, and goes on diminishing till the tenth year, when it ceases." The evil influences of

INTERBREEDING is a subject too extensive to enter upon at any length. In plants it is corroborated by the well-known advantage of crossing of varieties. But it needs no confirmation, for there are self-impotent plants, plants more thoroughly fertilised by a nearly allied species than by pollen of their own species, and there are the wonders of dimorphism with sterility arising from union of individuals not only of the same species, but of the same form. In the works of horticulturists is to be found ample evidence that interbreeding of plants tends to weakness, malformation, and sterility. The influence of heat and of cold is, in plants, well illustrated by the failure of most alpine species to produce flowers and fruit in lowland gardens, and the same failure of lowland plants as they ascend the sides of mountains. A walk in the highlands will show the Pines thriving on the hillsides and well covered with cones, but as greater altitudes are reached the trees are observed to become stunted and the fruit entirely to fail. The abortion-like sterility of plants is illustrated by the bearing of

DOUBLE FLOWERS, of flowers whose seeds do not ripen, or whose seeds, though apparently perfect, are incapable of germination and growth. In some of the cases of seedless fruit and of fruit with few seeds or with one seed, or with imperfect seed, we have also abortion and at the same time a fine illustration of the working, locally, of the opposition between individuation and genesis. The whole plant, as the Vine or Pear tree, may have the appearance of health, and its fruit alone is unnatural. The tissues of the fruit-capsule are enormously developed, while the seeds have disappeared or are reduced to one or a small number. The luscious

Pear or the juicy Grape are masses of hypertrophy or myxomatous-like degeneration while the seeds are the subject of extreme hypoplasia. Gardeners generally ascribe these results to overfeeding and overstimulation by manures and heat, but Darwin is more cautious, and in most cases does not analyse the causes further than is implied in "unnatural conditions of life." No one, according to Lindley and Darwin, has produced double flowers by promoting the perfect health of the plant. Before leaving vegetable physiology I would point out the frequent occurrence in plants of seeds which, though apparently perfect, will not germinate; they cannot be distinguished from their neighbours otherwise than by their incapacity for growing. The same failure to grow is often observed under closely similar circumstances in eggs; they cannot be hatched, although no imperfection is discoverable in them.

NOTES FROM TIMOR.

THE island of Timor differs considerably from Java, Borneo, and islands to the west; the seasons are much more decided, and the dry period of greater duration. At this season the shade temperature during the day ranges from 85° to 90°, and at night falls to about 75°, thus placing it, as a residence, at an advantage when compared with the above-named places, where I have sometimes found a difference of but from 5° to 8° in twenty-four hours. Added to this, Timor, or at any rate Koepang and the surrounding country, is almost free from that curse of warm, moist countries—mosquitoes. The vegetation resembles that of Australia in having numerous Eucalypti (called by the natives "Kayu Putie"), scrubby Acacias, and similar plants scattered over an undulating country, where run half wild the numerous ponies for which the island is somewhat celebrated. The families of Aroidæ and Zingiberacæ, so exceedingly common in the islands westward, are here represented by comparatively few species. Orchids are also much rarer than in the more humid islands; they probably do not exceed a dozen species. Of these three at least are horticulturally interesting, one of them being the true *Vanda insignis*, which until recently was almost unknown in collections. This is found growing on low trees in exposed situations in the warmest parts of the island. Malvaceæ is strongly represented; at least half-a-dozen species of *Hibiscus* might be collected close to Koepang, and several species of *Sida*.

A great proportion of plants in this island are furnished with spines, so that in riding across the country for a few days one's clothes suffer considerably. Very little of anything is cultivated, though parts are said to be specially adapted for Coffee and Cocoa. At the present time there is no security for capital, as Dutch rule is only nominal in the mountain districts. The principal exports are sandal wood and bees-wax, neither of which require any attention, and are consequently exactly suited to the Timorese. The natives live in houses almost exactly resembling an old-fashioned straw bee-hive; a small hole on one side, about 3 feet in height, serves the double purpose of door and chimney. The fire is in the centre, and the only way to escape semi-suffocation is to lie down as near it as possible. Their principal food is Maize and dried buffalo flesh, and their drink laroo, a preparation from the juice of *Borassus flabelliformis*. This is not used in the sweet state as obtained from the tree, when it is by no means disagreeable, but boiled and mixed with various bitter roots. As a drink it is worse than the sourest cider. There is another fan-leaved Palm common everywhere near the coast, from the leaves of which mats, ropes, and other materials are made, and its stem yields a coarse kind of sago. When fruiting it has a curious appearance; all the leaves drop off, and there remains only a straight stem terminating in an immense pyramid of small fruits. When required for sago it is cut as soon as it shows signs of flowering.

FRUITS are not numerous. Guavas and Custard Apples abound in a wild state near the

coast, and a native Grape with clusters of purplish berries is often met with. Mr. Wallace speaks of th's as having a luscious flavour, but I cannot endorse his opinion. Mangoes, Oranges, and a few other fruits are cultivated sparingly near the coast, but in the mountains nothing but the bare necessities of life. The island of Semaio, separated only by a narrow strait, produces an abundance of Water Melons, which are brought to Koepang. Generally, near the coast the soil is poor and stony; pointed limestone rocks crop out everywhere; often for a long distance there is not a particle of soil. Where there is a little, Maize is planted, and a rude fence is constructed round it by piling up the loose stones as a protection from buffaloes and other animals.

C. CURTIS.

KITCHEN GARDEN.

PEAS PODDING TO THE GROUND.

MR. MUIR's fault with the Ne Plus Ultra Pea was that it did not bear pods down to the ground, like varieties he said he could name that did. He was asked to name or produce these, but he has not done so, and I can only guess why. I will give him more rope, and ask him to name any Pea of the height and habit of the Ne Plus Ultra that bears pods any nearer the ground than it does under equal conditions. I should be willing to submit the Ne Plus Ultra in a cooked state to any set of judges, along with other sorts, at the right season, and risk their verdict, except, perhaps, with Veitch's Perfection, which is a sweeter Pea, but less prolific. Ne Plus Ultra is of the best flavour, grows well, and bears abundantly, and I would like to know what more anybody wants in Peas for eating. It does not produce long exhibition pods as a rule, hence is not a Pea for the show table, where in nine cases in ten the prize is given to the longest and fullest pods, but which, I have often noticed, no one would grow for cooking purposes. Is this not a farcical way of estimating the qualities of Peas? It is useless, however, trying to talk down a Pea that everybody likes and grows, and which seedsmen sell by the ton, as they do Ne Plus Ultra. I am not going to Wales to see Peas I can see nearer home, but I will endeavour to go and see the "Pea prodigies" of Mr. Muir that bear from the ground upwards when they are ready. He has distinctly stated that he can name such Peas, and no doubt grows them, and he ought either to name them or let them be seen.

J. S. W.

MUSHROOMS.

WILL you kindly inform me whether the enclosed is a good edible Mushroom, and of what variety? Its appearance struck me as peculiar, but all that are growing in the bed look just the same. How is an edible Mushroom to be distinguished from a poisonous variety?—W. F. V.

** The fungus sent is a good, edible Mushroom; the different varieties are often very diverse from each other in external appearance. The crucial points of distinction between true and false Mushrooms were given in the first volume of THE GARDEN (p. 16), and as the season for Mushroom gathering is at hand, perhaps their reproduction, as follows, may be of service. "First, and foremost, the true Mushroom (*Agaricus campestris*) is invariably found amongst Grass in rich open pastures, and never on or about stumps, or in woods. Many cases of poisoning have occurred owing to the supposed Mushrooms being gathered from stumps or in woods; it is true there is a certain variety found in woods and woody places (*A. silvicola*); but, as far as amateurs are concerned, it is best left alone. A second very good point is the peculiar, intense purple-brown colour of the spores (which are analogous to seeds); the ripe and fully-mature Mushroom derives the intense purple-brown colour (almost black) of its gills from the presence of these innumerable coloured spores. To see these spores, and so become acquainted with the peculiar

colour, remove the stem from a Mushroom, and lay the upper portion, with the gills lowermost, on a sheet of writing paper; in a few hours the spores will be deposited in a thick, dark, impalpable powder. Several dangerous species, at times mistaken for this Mushroom, have these spores umber-brown or pale umber-brown in colour, and belong to *Pholiota* or *Hebeloma*. In the accompanying figure is shown a vertical section of the true Mushroom, which differs (when the colour of the spores is taken into consideration) from

True Mushroom (*Agaricus campestris*).

almost all other *Agarics*, and certainly from all poisonous ones. One of the principal points to be observed is the distinct and perfect collar at C, quite encircling the stem, and the edge of cap at B, overlapping the gills; in some poisonous allies, as *A. ceruginosus* (generally found on and about stumps), this ring is reduced to a mere fringe, and the overlapping margin is absent, or reduced to a few mere white flecks or scales. Lastly, the gills never reach or touch the stem A, for, on inverting a Mushroom, a blank space will be seen all round the top of the stem where the gills are free from the stalk.

Section of true Mushroom.

There are innumerable varieties of the true Mushroom and of the horse Mushroom, but all are equally good for the table; sometimes the top is white and soft, like kid leather; at other times it is dark brown and scaly. Sometimes, on being cut or broken, the Mushroom changes colour to yellow, or even blood-red; at other times no change whatever takes place. But, observe, the Mushroom always grows in pastures; always has dark purple-brown spores; always has a perfect encircling clothy collar; and always gills which do

not touch the stem, and a top with an overlapping edge." W. G. S.

Globe Artichokes.—Plants having such large leaves as Globe Artichokes require a good deal of support in summer if the flower-heads are to be large and succulent. Rich mulchings and frequent supplies of liquid manure will be of great benefit now. To give a successional character to the crop the flower-stems should be removed now from a part of the plants. This will cause a new crop to spring up later on, when they will probably be more valuable than now.—E. HOBDAV.

Cutting Cabbages.—In garden culture Cabbage stems are commonly left for the sake of the successional crop produced by them later in the season. As in large establishments young, tender Cabbages are always in demand, and the second crop equal to a threefold one, often more, the leaves should be left on the stems for a week or ten days after the Cabbage has been cut, as in that time the young sprouts will be pushing out to supersede them. No plant, not even a Cabbage, should be denuded of all its leaves at one time if we wish to gather another crop from it.—E. HOBDAV.

Diseased Cucumbers.—I enclose two specimens of diseased Cucumbers. The plants which produced them were looking healthy and strong until quite lately, and now the whole crop is affected in the same way, so that all the plants will have to be destroyed. Can you give me an idea as to the cause of the disease, or tell me of a way of preventing it? The plants were grown in a well-constructed pit, and great care was taken in the watering. The outside linings, too, were removed when cold. I have never seen the disease so bad before, and never in this particular pit.—COBHAM.

* * * Your Cucumbers are suffering from an uncommonly virulent attack of gummy, immediately recognised by the excretions somewhat resembling gum-arabic. This disease is often accompanied by other ailments both of a fungoid and animal origin, and it may be so in your case. The disease and mode of treatment have often been described in back numbers of THE GARDEN, but when so bad as the specimens in question indicate, the best way would be to destroy the plants, and, after a thorough cleansing, begin afresh.—W. G. S.

Magnum Bonum Potato.—I have read with some surprise what "Grower and Exhibitor" has written (p. 571) respecting this Potato. He certainly has rushed to a conclusion on small premises, for seldom have I seen this Potato looking better than it does this year. It would not be difficult for me to see, in a few hours' walk, 100 or more acres of Magnum Bonum growing on many diverse places and soils, and yet all looking singularly well; indeed, the common observation here is not only how well Potatoes look generally, but how well the Magnums look. I have no doubt that for one acre of Champions four of Magnum Bonum are grown for the supply of the London market. "Grower and Exhibitor" must be singularly ill-favoured in the way of soil or seed stocks, but it is specially remarkable that whilst such kinds as Regents and Schoolmaster look so well with him, a kind which almost universally does better than either should be so indifferent. In Reading Hero, although it produces good and handsome tubers, the top growth is enormous, and, indeed, I have dug quite as good crops from round whites that have been content to produce one-half the haulm that the Hero does. Here, too, where Potatoes always are of capital table quality, the Hero does not excel Magnum Bonum when cooked. It is true that Potatoes this spring were generally late in starting into growth, but that probably kept the tops out of harm's way. The season so far, however, has been most favourable, and the growth has been all that could be desired. Beauty of Hebron and one or two others show some gaps, but all over the great mass of varieties nothing could be better than are present appearances.—A. D., *Bedfont*.

ASPARAGUS.

THE old errors about Asparagus and the old mis-statements were trotted out again last week in the *Chronicle* by a writer who does well not to sign his name. The paragraph is as full of mis-statements as it has lines, showing the complete innocence of the writer as to every condition of the question. That the Asparagus which was shown at Kensington, and received prizes there, was "tasteless and inedible" is untrue; it was pronounced by one of the best judges in Covent Garden to be among the best samples he had ever seen. We speak of Mr. Gulliford, who acted as judge, and who is not likely to give prizes for tasteless and inedible "rubbish." The whole assumption of the writer that the blanched part of the stem is rope, &c., is pure nonsense, because all intelligent cooks make it perfectly edible and good in flavour if the shoots be fresh.

The question of blanching it more or less is apart from the question of cultivation, and people may adopt the best system of culture without blanching, if such be their taste.

These prizes were not offered to cause Asparagus to be blanched, and the exhibitors are in no way bound to blanch. The conditions as to Asparagus and its blanching for market purposes have been settled for many years, and are not altered or disturbed by these prizes. That one or many should prefer in their private gardens this vegetable in a certain state of greenness is a common experience; but that is a different thing to condemning, as this writer does, the practices that growers have found essential for the marketing and profitable culture of Asparagus. That the writer knows little of the general question is proved by his assumption that the blanched stem is necessarily "hard, tasteless, and non-edible." Throughout a large area of Europe Asparagus is blanched completely, and always by choice of the eater. We are not now speaking of the partially blanched shoot of the London or Paris markets, but of heads *white* from point to base. The flavour of the last in a fresh state is not only good, but thought by some to be the most delicious of all!

We need not speak of the taste and modesty of terming the best produce of our good growers—Messrs. Harwood, Poupart, Allan, Speed, Cole—as "uneatable rubbish." A visit to these men in their gardens would soon convince the writer of the monstrous injustice of his remarks. If the writer professes to regard only the private garden aspects of the matter, and insists that Mr. Poupart, who, too, showed longest Grass the other day, showed "rubbish," we may refer him to Mr. W. Allan, of Gunton, and Mr. Speed, of Penrhyn, both good gardeners, whose crops, which we have seen, are excellent.

—Having read the remarks in the *Chronicle* upon the Asparagus exhibited at South Kensington, I am surprised the writer so strongly condemns blanching. He has made a molehill into a mountain. We do not earth up half as much as he imagines. The Asparagus exhibited is what is most appreciated in Covent Garden Market, and just such as realises the best price. If greener it would fetch less money, and I think I may safely place the opinion of a discerning public as regards such matters before that of an individual. I have cut my last lot to-day (25th inst.). The best of it was about 10 inches in length; 3 inches of it above ground was pale green, and 4 inches next to that was pinky white; the bottom 3 inches was white as ivory and brittle as a Cucumber, and, if cooked fresh, edible almost the whole length. The great thing with Asparagus is to cook it as fresh as possible—the fresher the better. The "absurd notion," as he calls it, of earthing still remains, and will remain as long as blanched produce fetches the most money. What the writer in question seems to want us to produce we call sprue—material hardly worth the trouble of cutting. He disagrees with the size of our Asparagus; but let me tell him we intend to grow it larger, if possible, the Argenteuil system having found favour with those who have tried it. In fact, some of the longest and largest heads shown at

South Kensington were grown on that plan. Let any grower of Asparagus draw a little loose earth round any large head he may see during warm weather, let it run 9 inches higher than usual, cut it and cook it the same day, and I feel sure he will find no rope-making material in it. If, however, it was kept a few days in hot, dry weather, it would doubtless become as tough as foreign Asparagus is.—A. J. HARWOOD, *Colchester*.

FLOWER GARDEN.

THE VERBENA AND ITS CULTURE.

FEW plants are more effective when well grown and flowered than the Verbena; but from some cause or other, although once extremely popular, Verbenas are now-a-days comparatively but little grown. It is said that the bedding kinds have degenerated to the extent of being no longer reliable, but my opinion is that over-propagation has had much to do with the failures so often experienced in the outdoor culture of this plant. Very often only a few potfuls are struck in autumn where thousands are wanted by bedding-out time; therefore, high pressure must of necessity be resorted to during the early spring months in order to secure the desired quantity. These spring-struck plants are, however, never equal to those propagated late in the summer, and which have never experienced undue excitement. Then, too, more pains should be taken to secure good cuttings. An experienced propagator once said to me, "It is all very well to say that Verbenas strike like weeds, but you must have the right kind of wood, and you cannot always get it." The first part of this sentence is, I know by experience, correct; the latter I do not endorse, as good cuttings can be had by taking proper measures. It is scarcely reasonable to expect that plants which have profusely bloomed under more or less trying circumstances should furnish good cuttings; and although in some seasons, marked perhaps by unusual geniality and under very excellent culture, the plants may continue to produce succulent wood, disappointment and failure are at times sure to result from relying on flowering plants for purposes of propagation. A safe and easy plan is to set out a few plants by themselves, which, being well attended to, and not being allowed to flower, will be in good condition when the time comes to take the cuttings. These need not be the best plants, but such as are left over at bedding-out time, as not flowering they will naturally grow rapidly.

PROPAGATION.—The last fortnight in August I consider to be the best time for propagating Verbenas, as there is then time to harden off the young plants by full exposure to sun and air before housing them. The points of the shoots naturally make the best cuttings, but any portion of the stem, if succulent, will do. As the Verbena roots all down the stem, it is not necessary to cut the cuttings to a joint. Some make a practice of filling the pots nearly to the rim with light, sandy soil, merely surfacing with sand, but I prefer to use enough pure sand to allow of the complete reception of the cuttings, for, although it is absolutely necessary that they never flag from the time they are put in until they make roots, it is just as indispensable that they are perfectly guaranteed against stagnant moisture. A surfacing of some 2 inches of silver sand will allow of the comparatively free use of the water; the sand will not, unless drainage be defective, become sour or waterlogged. A handlight or frame in a north aspect is the best place one can have, and I need scarcely say that the cuttings should be preserved against draughts or hot air during the day, keeping them in a general way quite close, but giving a little air on very damp days, and removing the covering for an hour or so in the morning, allowing it to remain off all night when the weather is very still and warm. Nothing invigorates them more than such a dewy bath as they then get, and if they are covered before the night's dew dries off, they will

be sure to remain fresh all through the day without watering, no matter how hot or dry the weather may be. When they have made roots, as will be shown by young shoots pushing from the eyes, remove the covering except in very wet weather, and eventually place them in a sunny place until housing time. This treatment will give strong, bushy, well hardened plants, very different indeed from those put in, as is often the case, so late that they are barely rooted by October. I should, however, mention that when the pots can be plunged in gentle bottom heat, the cuttings will root more surely and readily. Where large quantities of Verbenas are required it is often found necessary to resort to spring propagation, in which case there is even greater need to become a good and early strike the previous summer. With a good command of heat from February till May one may work up a stock of many thousands from a few potfuls of cuttings. By continually taking off the tops, which will under favourable conditions be young plants in less than a fortnight, it will soon give a crop, also increase will go on at a very rapid rate indeed. The stock plants should, however, be kept quite cool until the beginning of January, and 50° to 55° will do for the first month. If the most is to be made of the plants, do not pot off until the latter end of April, as the check occasioned by so doing will cause loss of time. What is sometimes called the sand and water method is a good one for Verbenas, saving trouble and giving good results quickly. Ordinary pots are filled nearly to the rim with sand, the cuttings are dibbled in and the pans kept filled with water. In this way they never flag, not even in the full sun, and the pans may even be stood on a warm pipe, roots being quickly made if the pans are kept full of water. This plan involves less labour than any other, and greatly facilitates potting off, as the cuttings may be simply drawn out of their semi-liquid rooting medium and potted without check. Now that it has been found possible to fix the various decided colours of Verbenas, the substitution of seedling plants for those obtained in the ordinary way will in all probability be extensively practised. Seedlings always possess greater vigour than cuttings, and this extra store of vitality and strength enables them better to resist the disease and partial paralysis which often seizes on the Verbena in the open. Seed sown in warmth early in February will, if the young plants are pushed along for a time, give nice little specimens for planting out the latter end of May.

OUTDOOR CULTURE.—It may appear superfluous to warn Verbena growers against anything approaching stimulative treatment in winter, but the necessity of keeping the plants cool and almost in complete rest from November until March is so great, and the neglect of it so fraught with danger, that I venture to call particular attention to this part of the subject. Not that I approve of the extreme cool treatment oftentimes practised, and which consists in simply keeping out frost. The very low temperature, accompanied by the great amount of humidity which so often prevails for some days together, is not good for Verbenas; they like a dry atmosphere, and consequently a little fire heat in periods of cold, damp weather. The foliage then remains green and healthy, and the roots continue in their normal state of activity. They are full of restrained vigour, and go ahead finely when set out in the open ground later on. Although the above remarks may not appear to harmonise with the accompanying heading, they do so really, as on the winter management depends to a great extent the progress in summer, and the difference between plants which have been wisely managed and those which have been allowed to struggle through as they may is really marvellous. A mistake often made is that of keeping the plants too long under glass. After the middle or indeed the beginning of March the proper place for Verbenas intended for bedding out is a cold frame, as whatever growth is made from that time onwards should be, as it were, hardened as it is made. The lights being pulled off on fine days and left off during the night in balmy weather,

both foliage and wood retain great substance, and the plants are in this manner better prepared for their permanent positions in the open than by any other means. One great advantage gained by this treatment is that of being able to plant out at a much earlier date, as the plants are thereby endowed with such a hardy constitution as to bear with much indifference the cold nights and bleak winds incidental to the earlier part of the month of May; whereas, when kept constantly under glass until the middle of May they can scarcely be set out before the last week of that month. The plan commonly followed of potting *Verbenas* off singly into small pots where they are eventually to be planted out is not a good one. The better way is to put two plants into the same pot, one on each side of it, as then the separation which takes place at planting time loosens the soil and the roots somewhat, and they always seem to thrive better in this way than when set out with balls entire. From May 20 to the first week in June is the time most often chosen for planting, but if you desire an early bloom and wish to see the *Verbena* at its best, do not be later than the end of April, but of course some little protection will be needed should hard frosts occur. Flower-pots will do very well, and when the days are very cold they may be left on all day, as sufficient light will enter by the drainage holes, especially if they are enlarged a little. I have seen fine beds of *Verbenas* grown in this way in light soils when by the ordinary method there would be but little chance of succeeding. Where the natural soil is very porous, some endeavour should be made to render it more firm and holding. A few barrow-loads of clay laid on in winter and worked in when it crumbles in spring will work wonders, but good sound loam is still better. *Verbenas* like good rich earth, but beware of raw manure, which will do more harm than good. Manure should be not less than twelve months old when used for them.

POT CULTURE.—The flower gardener may certainly pass his time less profitably than in growing a few specimen plants of *Verbenas*, and I think many more would do so did they but know how many fine varieties there are which in richness, brilliancy, delicacy of colouring, and general effectiveness are surpassed by scarcely any other summer blooming plant. The fact is a very large proportion of the numerous kinds of *Verbenas* which have been raised during the last few years are not quite happy in the open air, being probably too high-bred to resist the extremes of moisture and drought to which outdoor plants are often subjected, but under glass they bloom well, the trusses coming remarkably large, much larger than the best outdoor culture can effect. In order to succeed with the *Verbena* as a pot plant, all that one has to do is to select free autumn-struck plants, and grow them along briskly in a cool greenhouse or frame, pinching now and then during the early portion of the season, shifting before they get root-bound, and keeping them free from green fly. The last shift should be made in June into 8-inch pots, at the same time inserting four or five stakes round the edge of the pots to train the shoots to. Be sure not to coddle, but to give abundance of air, and if mildew appears dust at once with sulphur. Good fibrous loam, with some well decayed manure in it, is the best soil for them. J. C.

Byfleet.

Impatiens Sultani.—I find this pretty Balsam to grow freely from seeds, so that being easily increased both by means of seeds and cuttings, it will doubtless before long become as popular as it well deserves to be. I may mention that *Impatiens alba*, a plant rarely seen, forms a good companion to it, being in general character the same except in colour; indeed, it may be best defined as a white counterpart of the Zanzibar Balsam. When the seeds are ripening care must be taken that they are not lost, as the capsules expand with such force as to scatter them in all directions; therefore when the pods are approaching maturity they should be enveloped in a gauze bag, which will retain the seeds.—H. P.

BERNARD'S HYBRID NARCISSUS.

(*NARCISSUS BERNARDI*.)

A LADY who now and then enjoys a little tour on the Pyrenees, and is mindful to bring or send from thence choice floral treasures for her garden, found a bulb or two of this plant a year or two ago, and has now quite a strong clump of it in her rock garden. It is a little known plant in cultivation, but has long been known to botanists, being figured by M. Henon, and it is also described in Grenier and Godron's "*Flore de France*." It is generally thought to be a natural hybrid be-

these natural hybrids from the Alps, that did we know less of them we might be tempted to make a new variety (if not a species) of the one now figured; but species making is not the fashion now that it once was, and we are quite willing to call this *Narcissus* a form of *N. Bernardi*, although it differs in one or two points from M. Henon's figure. It is of tolerably robust habit, having stout glaucous leaves, and its flowers are of creamy whiteness, so far as the perianth divisions are concerned, the cup varying from yellow to deep orange-scarlet; and, as we have before indicated, the relative pro-

Narcissus Bernardi.

tween *N. Pseudo-narcissus* (var. *muticus* of Gay) and *N. poeticus*. It is quite distinct from *N. incomparabilis*, its perianth divisions having more substance and the leaves are broader—indeed there is a *N. Nelsoni* look about the plant which removes it quite out of the *N. incomparabilis* group, so far as my own opinion is concerned. And yet this *N. Bernardi* is a variable plant, even naturally, and culture increases its stature and the size of its flowers. Turning over my sketches of *Narcissus*, I came across a form of *N. Bernardi* sent to Mr. Barr from the Pyrenees two years ago, and its flowers are quite different from those now figured, inasmuch as the petals are smaller in proportion, and the cup or crown larger, and with a rich suffusion of orange-scarlet quite suggestive of a little known *Narcissus* already figured in *THE GARDEN*, yeleft *N. Nelsoni aurantius* (*vide THE GARDEN*, Vol. XVI., p. 174, fig. 7). So distinct are some of

portions of perianth divisions and cup are apt to vary pretty considerably. As a garden plant its late blooming habit is a great recommendation, as it naturally blooms along with *N. poeticus* fl.-pl. during the bridal time between May and June. Planted in sheltered situations in deep moist soil, it grows freely and increases rapidly, having indeed that robust constitution which is characteristic of so many hybrid plants. All visitors to the Pyrenees should look out for its bulbs and flowers wherever the yellow Daffodil and Poet's *Narcissus* are seen growing side by side, for it is at present far too rare to appear in trade lists, even if it has actually gained a place in that wonderful bulb garden at Tooting where nearly all known *Narcissi* are for the nonce at home to privileged visitors. I am proud to say that a bulb of *N. Bernardi* is just now very happy in a deep rich border in the College Gardens. F. W. B.

FLORISTS AND THEIR FOIBLES.

I HAVE no intention of joining "Peregrine" in what he calls "the Scotch game of answering one question by asking another;" neither do I mean to identify myself one way or the other with the person whose views he so strongly condemns (see p. 529). My controversy has been with "Peregrine" alone, and arose from his own remarks solely. My attention was first called to him by his attack on the National Auricula Society, which he was pleased to say "numbered nearly half a dozen members," and by his condemnation of florists in general on the ground of their not being like butterflies and bees. In his succeeding remarks he goes on accumulating charges of narrowness and obstruction against the florists, which charges culminate in the statement (p. 445) that "none of the races of popular hardy flowers made any great strides in improvement until they were taken out of the florists' hands." If he could prove such a charge as this there would be an end of controversy, and the florists should hide their heads with shame as the worst foes to floriculture. If he could not prove it, I prefer not to characterise his charge. Consequently, I demanded from "Peregrine" a detailed list of the flowers which had been in the florists' hands which had been taken out of their hands, and which had made great strides in improvement in consequence. He has not thought well even to attempt the justification of his charge, but instead invites me to the Scotch pastime just mentioned. I leave your readers to draw their own inference, and to estimate the value of his remarks on florists and their foibles. "Peregrine" says that I am wrong in stating that he knows nothing and cares nothing for florists' flowers. If he does know anything about them—their culture, their properties, and their varieties—I have certainly not perceived it in his writings; and if he does care for them, I can only say that he has admirably succeeded in dissembling his love. Thanking you for your courteous admission of my remarks, I now take leave of "Peregrine."

Cloghran, Co. Dublin. FREDERICK TYMONS.

BARE EARTH.

IF I had but the poetical nature of "Veronica," I could just enlarge a bit on this subject; but then, Mr. Editor, you only allow about two of your correspondents to exercise this valuable gift, and you would therefore be sure to "clip my wings" if I dared to take a flight into the regions of poetry, and I won't (as you know) be clipped. I will, therefore, confine myself simply to what I have done, and do, in this matter of bare earth, solely from an ornamental point of view. The idea was suggested to me, "as most happy thoughts are," by accident, some years ago now—the accident being that we had too few *Pelargoniums* of a given variety for filling out the space that had been allotted to them in the summer bedding arrangements, and, being quite of "Veronica's" opinion as to covering all the soil, I was perplexed beyond measure to solve the difficulty, but industry was presently rewarded and my brain set at rest by the happy thought of filling in cushion fashion, as the ladies do their fancy slippers, with a ground colour of some other plant. I am not quite certain as to what was the variety of *Pelargonium*, but, I think it was Mrs. Pollock, and the plant used for filling in was *Ajuga reptans purpurea*, the effect being charming. Such was the beginning, the dawning of the idea that, unfortunately for my physical powers, has developed, and is still developing, for now we not only do this filling-in work when short of certain varieties of plants, but from choice also. I give you an example or two of our doings at the present moment. *Alternantheras* planted thinly, and *Sedum glaucum* intermixed; *Fuchsias* the same, and green *Sedum Lydium*; *Pelargonium Sophia Dumaesque* and *Herniaria glabra*; *Coleus* and *Sedum acre elegans*; large tree succulents, and the flowering and variegated creeping kinds of *Mesembryanthemum*; whilst, with respect to hardy perennials, the notion has got possession of me that all tall growers that do not cover the earth naturally

should have an undergrowth of dwarfers, but allied kinds of plants, there being dwarf *Saxifrages*, *Sedums*, *Phloxes*, &c., innumerable that are in every way suitable for such undergrowths, and which I purpose to press into service as time and opportunity offers; then, as "Veronica" remarks, "weeds will have no chance." W. W. H.

ROCKETS.

FROM the notes of "Veronica" and others I gather that the old double white Rocket is getting scarce, which is a great pity, as it is the sweetest by far and the most charming of all the varieties of this lovely family. It is far more compact in the truss than the French variety, which one much more frequently sees now than it. I have five varieties—the old white; the French white; one that on first opening has the faintest tinge of lilac, but which becomes perfectly white; the pale lilac, which continues that colour always (this last has the grandest spike of any and the largest flowers); and fifthly and lastly, the purple—not, however, the old purple, a beautiful plant which made spikes in soil it liked nearly 2 feet long, and which was very delicate, but a hardier kind, which only attains to about 3 inches or 4 inches in its spike, but which still is a beautiful contrast with the white. If "Veronica" has not got the old white, and would send me his address, I would give him a plant later on. I wish very much that I could hear of anyone possessing the old purple, as it is a thousand pities that such a treasure should be lost. And I also wish that M. Max Leichtlin would tell me where the rose-coloured one he speaks of as blooming at Baden-Baden is to be procured, for if really rose-coloured it would be most valuable. I wonder very much at "Veronica" leaving the side shoots on his Rockets. They give the whole plant a weedy appearance, and rob it of the stately aspect it wears when rearing its grand spikes aloft. Lovers of Rockets should be sedulous to keep diligent search during the spring months for the odious Rocket grub, which, if not found and destroyed, will entirely ruin the bloom.

Virginia Rectory, Ireland.

DENIS KNOX.

BORDER V. BEDDING PLANTS.

I AM among the ever-increasing number of those who grow and admire hardy and half-hardy perennials, and who prefer a mixed border containing perhaps fifty distinct varieties or species of plants to one arranged in ribbon fashion with only five. These five may have been the same identical kinds that occupied the same border for the previous five years. THE GARDEN does well in assisting to put an end to bedding. There is no reason why mixed borders or beds should not be showy, and why, if need be, some regard should not be had to height, colour, and effect. This cannot be learned in a moment. A full and perfect acquaintance there must be with every plant used, with its habit of growth and time of flowering before that can be accomplished. It may then at once be conceded that the amateur or gardener who successfully grows flowers and uses with effect the aforesaid fifty varieties or different species of plants is much more skilful, and has acquired a more extensive knowledge of plants than the ribbon border or bedding-out man who has only to do with a fraction of that number. But while the former acquires a more extended acquaintance with the larger number dealt with, there is also an enlightened pleasure and satisfaction in watching their progress to maturity and expansion into bloom the whole year round, and that bewitching anxiety to see what one's seedlings may be like. This pleasure the mechanical bedder of *Pelargoniums*, *Lobelias*, *Calceolarias*, *Iresines*, &c., never knows. Why, it would be far more interesting to go in for one or more of the florist flowers, grow them from seed, improve them by hybridisation, and have a bed of each of the best, and watch the effect. This would be the remedy for those who complain that one requires to know too many and too much. Take Pansies—I cut sixty distinct varieties from sixty beds within the last few days—show, fancy, and self.

There are also the hardier *Auriculas*, *Polyanthuses*, *Primroses*, *Dahlias*, *Fuchsias*, *Carnations* and their allies, *Picotees* and *Pinks*, *Begonias*, *Antirrhinums*, *Pentstemons*, and other large species having varieties enough to stock a whole garden, such as the *Pæonies*, *Campanulas*, *Saxifrages*, *Phloxes*, *Anemones*, *Delphiniums*, *Gentians*, *Liliums*, various *Compositæ*, including such good things as *Doronicum*, *Harpallium*, and *Rudbeckia*, which I would bracket together, and so on. To succeed, however, propagation must go constantly on. W. J. M.

Clonmel.

5018.—**Water Lilies.**—"Welshman" may safely plant any *Nymphaeas* in ponds where the climate is "a Madeira one." The space he has (16 yards) will accommodate, say, eight plants. A good selection would be *N. stellata* or *scutifolia* (blue), *N. gigantea* (blue), *N. Lotus*, *N. odorata*, and *N. dentata* (white), *N. Devonensis* and *N. Lotus* var. *rubra* (red), *N. flava* (yellow), and *N. versicolor*, *N. odorata* var. *rubra*, and *N. alba* var. *rosea* (variously coloured). Other plants suited for the position described are *Limncharis Humboldtii*, *L. Plumieri*, *Eichornia azurea*, and *Pontederia crassipes*.—B.

The old double white Rocket.—I was in great joy at seeing a note under the above heading in THE GARDEN (p. 558); but when I came to read it my joy lessened, as I fear it is very far indeed from certain that the plant referred to as growing at Eglinton Castle is the genuine old double white Rocket, or, as it used to be called, the Paper-white Rocket. I have known the plant from the time I could know anything, and it was the only double white grown in this garden, where it was in profusion until about twelve or thirteen years ago, when it suddenly and completely died out here and in the gardens of relatives and friends in various parts of Ireland. I should rejoice, for old acquaintance sake, to think that it still survived at Eglinton, but one or two words in your description of that variety make me doubt that it is the old Paper-white. In the first place, the old kind would be far more appropriately described as neat than as massive, an epithet which exactly fits a well-grown spike of the kind now commonly grown and known as the French White. In the next place, the old kind was never "widely branched at the base." It was smaller in all its parts, foliage, stem, and flower as well as spike, than the existing kind. It gave but few and insignificant branches from the main stems. In these respects the Eglinton plant does not agree with the old kind. Not having seen the flower which you describe, I cannot tell whether it possesses the peculiar characteristic of the old sort, namely, absolute purity of colour, not a trace of pink or lilac even in the centre of the flower. Although I should be glad to get back my old friend, still the kind which I have is superior as a decorative hardy plant, with fine constitution, which the other had not.—FREDERICK TYMONS *Cloghran, Co. Dublin.*

* * The Eglinton Castle Rocket is said to be the true old Scotch kind. One border planted with it is 283 feet long and 6 feet wide. It contains over 1200 plants, all now in bloom, and many carrying 8 spikes—a grand display.—ED.

SHORT NOTES.—FLOWER.

Calla æthiopica is hardy here. Three years ago I planted some in an old bee-hive, and plunged them, hive and all, in a pond in my garden. They have survived three winters (including the terrible one of 1880-81), and are now in flower, the blossoms being as large and strong as could be produced under glass.—WILLIAM WICKHAM, *Binsted-Wyck, Alton, Hants.*

Viola Mrs. Gray was raised here several years ago. It was tried along with many other white seedlings, and was found to be quite hardy, sound in constitution, and dwarf—even creeping—in habit. We find it also very useful in a cut state. We have over 8000 planted, and some in borders two years old are masses of pure white bloom. Some idea of its hardness may be formed when I say that last winter after eleven days of frost, ranging from 4° to 19°, we gathered blooms.—JOHN GRAY, *Eglinton Castle.*

5008.—**Violets in September.**—Czar and Queen Victoria are the best varieties of Violets for flowering in autumn; new plantations made from the strongest runners as soon as procurable in early spring never fail to produce an abundant supply of flowers from September onwards, and continue to flower till destroyed by severe frost. The best aspect for such a plantation is a border facing the west.—W. W.

Sowing biennials.—Canterbury Bells, Sweet Williams, Foxgloves, Antirrhinums, Columbines, and other hardy plants of a like character, which flower the second year may be sown now in the open border. They are best sown thinly in drills in a partially shaded position, such as that afforded by a border on the east or west side of a wall or fence. The soil should be well pulverised, and the drills, which should not exceed half-an-inch in depth, should be far enough apart to permit of the free use of the hoe after the young plants appear. If the weather is dry at the time of sowing, water the drills and sow on the damp soil, covering with dry surface soil to prevent the moisture from escaping by evaporation. A thin shade if the weather is very hot in the middle of the day will be beneficial to the sprouting seeds.—E. HOBDAK.

The Sun Roses (Helianthemums).—To fully enjoy the beauty of Sun Roses early rising is necessary; on sunny mornings they are fully expanded by seven o'clock, and by the middle of the day their flowers are entirely or partially closed. Despite this peculiarity they are, however, very gorgeous *en masse* when the weather is favourable, and will succeed where little else will thrive. The Sun Roses are small, procumbent shrubs from 6 inches to 1 foot high, and therefore are well suited for sloping banks or rockwork, even where the soil is chalky; indeed on some of the Surrey hills the common *Helianthemum vulgare* forms large showy masses. As they lend themselves readily to the operations of the hybridist, a large variety now exists amongst them, including white, yellow, crimson, and various intermediate shades. There are also single and double flowered kinds. Although classed as shrubs, their general aspect is that of herbaceous plants, so procumbent in habit are they. Should the day be very dull, the flowers do not open, but a long-continued succession is kept up, and in summer most days are sufficiently favourable for their expansion.—ALPHA.

Seedling Columbines.—I send a few flowers of Columbines for your opinion; some of them are quite distinct from their parents, which were *Aquilegia chrysantha*, *A. cœrulea hybrida*, and *A. californica hybrida*, there being no other kind in the garden except one of the commonest double forms. We find them to be most useful for arranging amongst cut flowers in vases, cutting them with moderately long stalks and keeping them above a groundwork of other flowers. With us they stand in water a fair length of time—generally three or four days, but they probably would not stand so long now, as the weather has been so hot and our honey bees have been hard at work among them.—C. WARREN, *Clarendon Park, Salisbury*.

** Beautiful hybrids, with delicate and most novel colours. They are very desirable in cultivation, and we have had many enthusiastic comments upon them from our correspondents, but those who have enjoyed the beauty of the finer wild species will rather seek to keep them pure and vigorous than to add to their hybrids. Their beauty, however, is very great, and a batch raised occasionally will prove useful.—ED.

Autumn-sown Sweet Peas.—These I find to be most useful for furnishing a supply of early flowers for cutting; they stand the winter well, and come into full bloom considerably in advance of spring-sown ones. Anyone having a sheltered position such as a boarded fence or even close to a hedge may get a very early supply of Sweet Pea blossoms by sowing in November, and as soon as the young plants come through the soil put a good covering of sifted coal ashes over

them; these act as a protection from severe frost, slugs, and even superfluous moisture. A few sticks should also be put to them early, as they screen them from cold winds that are more destructive to such plants than actual frosts. I find the scarlet *Invincible* to be a capital sort for cutting from, but as a rule mixed sorts are most generally useful. The colours can be selected as gathered if required for any special purpose, and the more closely the flowers are kept gathered the longer will the plants continue to produce them. It is seed-bearing more than flower-producing that exhausts the energies of the plants, and if kept well supplied with liquid manure, and a covering of good rotten stable manure is placed over the roots about 2 feet wide, the same plants will continue to flower the whole season. Sweet Peas are especially suited for filling vases either mixed with other flowers or by themselves, the latter being as a rule the most satisfactory arrangement.—J. GROOM, *Gosport*.

NOTES FROM COOMBE WOOD.

OF all seasons the present is doubtless the best for visiting a tree nursery, the foliage being now fully developed and still fresh and spring-like. Hence a correct estimate of the true character of the different subjects examined can be obtained. Never have we seen Messrs. Veitch's nursery at Coombe Wood so beautiful as now; everything seems so fresh, and, as usual, it teems with a host of interesting plants with which one cannot meet elsewhere. Among the most striking features of this nursery is its collection of

CONIFERS, which are now developing their new season's growth, and the contrast between the bright emerald-green of the young tips of the shoots and the sombre tint of the older branches is most striking. It is interesting to observe the various degrees of forwardness which the different kinds exhibit; some began to break into growth several weeks ago, and some are only just breaking. Among the late breakers is the very handsome Japanese Tiger-tail Spruce (*Abies polita*), and this distinct character makes it a valuable tree for northern districts in which late spring frosts are prevalent; even the latest would be past before the tender shoots of this Spruce unfolded. Besides the collection of older coniferous trees, one may see here a host of new ones, and some not yet put in commerce. Among the new ones are several Japanese species collected by Mr. Maries when travelling for Messrs. Veitch. Never till now had we seen the true beauty of the new *Abies Veitchi* and *Mariesi*, both recent introductions. The first bears some resemblance to Nordmann's Fir, but the branches are more densely set with deep shining green leaves, which are also somewhat shorter than in *Abies Nordmanniana*. It gives every promise of becoming a handsome plant, and if as hardy as *A. Nordmanniana*, it will be a real gain. *A. Mariesi* is distinct from all others, and though said to grow in company with *A. Veitchi* on the Japanese mountains, they seem to bear no near affinity to each other. It is a strikingly ornamental species, and, being perfectly hardy, will be an acquisition. The new Japanese Hemlock Spruce may likewise be seen here clothed with fresh young growth, as well as such beautiful kinds as the true *Abies concolor* and *amabilis*. The collection of conifers for the most part occupies a sloping bank, and in such a position the beauty of their young foliage can be seen to the best advantage. Another and perennial feature, though in one sense always changing, is what is called the specimen borders, which skirt a broad path that runs through the centre of this nursery. Here one may find well-nigh every kind of ornamental tree or shrub grown in gardens. At the present time those which arrest attention are the

JAPANESE MAPLES. These are now arrayed in their richest summer leafage. We more especially allude to the innumerable varieties of *A. polymorphum*, truly the most variable of all Maples. Judging by the splendour of the foliage on the specimens here, these Maples must be even now but little known, or they would be oftener met

with than they are. Some, such as *sanguineum*, have blood-red foliage, the effect of which, properly placed in a garden, would be charming. In this nursery, on one of the exposed sunny slopes, a broad mass of it has occupied its present position for some years, and has never been injured either by cold or heat, drought or excessive wet. The effect of this rich mass of colour—a deep reddish crimson—especially when seen from the opposite side of the nursery, several hundred yards distant, is very fine. In the specimen border are also some fine examples of the varieties *dissectum*, with finely divided, deep red foliage; *septemlobum*, also with dark foliage, and many other varieties, all beautiful, plainly showing the wealth of variety existing amongst these Japanese Maples alone. Scarcely less attractive are young shoots of two other Maples, *A. colchicum rubrum* and *A. platanoides Schweedleri*; the young leaves of both of these are of a rich red tint, retained for a long time, but longest by *colchicum rubrum*. These plants grown in large masses contrast beautifully with such ornamental trees as the Golden Oak (*Quercus Robur concordia*), the new Golden Elm (*Ulmus Dampieri aurea*), the variegated Negundo, and others.

Among the other Japanese Maples of recent introduction are *Acer crataegifolium*, which gives promise of becoming a useful fast-growing shrub, and the variegated form of it certificated at South Kensington a week or two ago is one of the prettiest of Maples. The bright red petiole of the leaves is a distinct and beautiful character of this species, and also that of the *Acer rufrum*, another Japanese introduction, with larger foliage. These and various other new Maples are being tested in every way as regards their hardiness, and up to the present they all seem perfectly indifferent to the severe cold of our winters. A sunny slope set apart in this nursery specially for new things in the way of trees and shrubs abounds with interest. Here may be seen trees from the antipodes in company with those from Chili, and Japan, and California, four widely separated regions, and it is a singular fact that all, or nearly all, are thriving, though quite unprotected during the past few winters. The Japanese shrubs are especially interesting, and those in flower just now are *Styrax japonicum* with clusters of white bell-like flowers similar to those of the Snowdrop Tree (*Halesia*). *Daphniphyllum glaucescens* promises to become a very ornamental evergreen, the Rhododendron-like leaves being of a silvery hue beneath. The greatest attraction, however, in this part of the nursery is a huge spreading bush of the single *Rosa polyantha*, which is indeed a beautiful sight, as each of its long slender shoots carry a dense cluster of white blossoms, the delightful perfume of which pervades the atmosphere around; a finer object for isolation on a lawn would be difficult to find. Among other noteworthy shrubs in flower is the beautiful *Zenobia pulverulenta*, one of the prettiest of all Ericaceous shrubs, which was exhibited at South Kensington on Tuesday last, and likewise the Californian *Leucothoe Davisæ*, which was certificated. Seen in the open air, this shrub is even prettier than it was at the show, and it is to be hoped that it is quite hardy.

PHILADELPHUS GRANDIFLORUS is the best of all the Mock Oranges in flower, and indeed of the whole collection, not even excepting *P. mexicana*, which was certificated a short time since. By far the finest white-flowered shrub in bloom is *Viburnum plicatum*, of which there are here some grand specimens, fairly smothered with snow-white clusters of bloom, each of the long slender shoots being wreathed in white. In a short time the beautiful *Escalonia Philippiana* will be a mass of bloom in various parts of the nursery, besides a host of other things. The fine new *Magnolia Soulangeana nigra* must not be omitted from the list of flowering trees. For some weeks past it has been laden with bloom, and still the large specimen standards of it quite in the open air are in flower. The huge blossoms, almost of a black-purple, have a very fine effect in the specimen border, where also we noted the new purple-leaved Plum (*Prunus Pissardi*) which has emanated from the Continent.

If perfectly hardy it will be a valuable addition to the list of pictorial trees, for the colour is equal to that of the purple-leaved Filbert, the variegated Tulip Tree (*Liriodendron*). W. G.

NOTES OF THE WEEK.

APPOINTMENTS FOR THE WEEK.

July 3.—South Kensington: Show of National Rose Society.

5.—Dublin: Summer Show of Royal Horticultural Society of Ireland.

Bath: Rose Show.

A DEPUTATION of market gardeners has arrived from Scotland for the purpose of urging the Government to include market gardens and orchards within the provisions of the Agricultural Holdings (Scotland) Bill.

A STEPHANOTIS HOUSE.—There is a house devoted to this plant in Messrs. Hawkins & Bennett's nurseries at Twickenham, about 150 feet long. It is now full of flowering plants in the most perfect health, and without a trace of insect pests of any kind. The culture is admirable, and the flowers gathered in the house for the market are of the finest quality.

STOVE PLANTS AND THEIR CULTURE.—We have made an arrangement with the well-known plant grower, Mr. Thomas Baines, for a complete series of articles on this subject. It is needless to say that their culture will be fully treated of, and in addition their propagation, which, if done at all in books of this sort, has never hitherto been well done. The series will embrace fine-leaved as well as flowering stove plants.

PRIZES FOR FRUIT PACKING.—On Tuesday next at the Horticultural Gardens, South Kensington, the competition for the prizes offered by Messrs. Webber & Co., fruiterers, Covent Garden Market, for the best examples of packed fruit will take place. These prizes, three in number, amount to 10 guineas. The exhibits must consist of one box of Grapes, not less than 14 lbs.; one box of Peaches, not fewer than two dozen; and one box of Strawberries, not less than 2 lbs. The boxes are to be sent by rail and delivered by the railway company.

HEUCHERA RICHARDSONI, commonly called the Satin-leaf Plant, is grown unusually well by Mr. Bedford, of Straffan, Kildare, judging by the size of some leaves of it which he sends us. The upper surfaces of these leaves, which measure 6 inches across, are very beautiful, being deep green, overlaid with a bronzy tint, and edged with bright green, the whole shining with a satin-like lustre. The form somewhat resembles that of a Vine leaf. This plant is being brought prominently into notice on account of its fine appearance, not only in the garden, but when mixed with cut flowers, its leaves lasting in perfection several weeks when cut.

SOWERBY'S ENGLISH BOTANY.—We have received the first part of the concluding volume of Sowerby's "English Botany," which has been in preparation for the last eight years. It will contain Ferns, Fern allies, and supplementary plants, and also a full index. There will be seven monthly parts, which will be issued in succession. The present number contains coloured plates of *Pilularia globulifera*, four species of *Isoteles*, *Selaginella selaginoides*, five species of *Lycopodium*, two of *Ophioglossum*, *Botrychium Lunaria*, *Osmunda regalis*, *Trichomanes radicans*, *Hymenophyllum tunbridgense* and *unilaterale*, *Polypodium vulgare*, *Gymnogramma leptophylla*, *Cryptogramma crispa*, and *Phegopteris Dryopteris*.

GLOXINIAS.—The prizes offered by Messrs. Sutton for a dozen Gloxinias at South Kensington on Tuesday last were so poorly responded to that only one lot, though a very good one, was staged. No doubt these plants when in full bloom travel badly, for the flowers are not of sufficient substance to withstand friction, and the packing of the flowers with a mass of wadding seems produces

tive of almost worse results. Then a dozen plants make a heavy and difficult parcel for transit anywhere, and at the most only a dozen diverse kinds can be shown. If the Messrs. Sutton wish, as they doubtless do, to encourage the cultivation of this lovely flower, we would suggest that in preference to asking for plants in the future, the prizes should be offered for cut blooms, say twenty-four kinds in bunches of three blooms, set up in a groundwork of *Selaginella* or Maiden-hair Fern. This would make one of the most charming cut flower classes, and in small shows might well be reduced to twelve kinds to meet the ability of small growers. There are dozens of growers who could carry a box of flowers to a show who would not bother themselves with a dozen large plants. —A. D.

COMMONS PRESERVATION SOCIETY.—On Monday last the annual meeting of this Society was held (by permission of the Duke of Westminster, at Grosvenor House. The president, Lord Mount-Temple, was in the chair. The report, which was taken as read, stated that protection from encroachment on rights of common was needed at Mitcham, Chislehurst, St. Paul's Cray, East Sheen, Keston, Epsom, Harrow Weald, and Stanmore. No act for vesting Malvern Hills in a properly constituted authority had been passed, as was hoped, last year. The Society's friends were congratulated on the recent dedication to the public of the Coudsdon Commons by the Corporation of the City of London, the movement for their preservation having been set on foot by one of its local branches. Lord Onslow, the lord of the manor, had notified his willingness to dedicate Merrow Downs, on the outskirts of Guildford, to the public if the Corporation of that town would apply for a scheme under the Commons Acts. No scheme had as yet been set on foot for the regulation of Ashdown Forest, but it was likely that next year application would be made. The rest of the report referred mainly to the more or less effective resistance to the attempted appropriation of rights of common by railway and other public bodies.

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 26.

THERE was an interesting display of plants on this occasion, and these, combined with the brilliant exhibition of the Pelargonium Society and the competition for special prizes, held under the same tent, made a most successful gathering. A large number of plants was submitted to the committee, to the following among which first-class certificates were awarded:—

CATTLEYA WARNERI.—This was a wonderfully fine form, designated Hardy's variety, and shown by Mr. Hardy, Pickering Lodge, Timperley. Its flowers were very large, the petals broad and of a delicate rose-pink, and the labellum was unusually broad and exquisitely coloured. On the lowermost lobe was a large blotch of amethyst; this was margined towards the throat with a band of white, and beyond that was a conspicuous blotch of citron-yellow, while the whole margin was beautifully frilled and tinted with rose. The only fault the flower possessed was an inordinate flopping of the sepals and petals. The plant, a fine one, bore two large spikes.

PRITCHARDIA GRANDIS.—This noble fan-leaved Palm, lately introduced from Borneo, and shown by Messrs. Veitch, is destined to become one of the handsomest dwarf Palms in cultivation. It was admired by all who saw it.

BEGONIA PRINCE ALBERT VICTOR.—An extremely fine double flowered variety of the tuberous-rooted section. Its flowers are large, and the petals form a perfect rosette of bright cherry crimson. The plant, a sturdy grower and well furnished with blossoms, was exhibited by Messrs. Laing, Stanstead Park Nurseries, Forest Hill.

RHODODENDRON DIADEM.—A new seedling variety of the Javanese section raised by Messrs. Veitch & Sons, who exhibited it. The truss is

large and dense, and the flowers individually good in form. Colour, a bright orange-scarlet.

YUCCA GLORIOSA VARIEGATA.—A new form of the common hardy Yucca, in which the leaves are variegated with longitudinal bands of yellow and a rosy pink tinge with green, much in the same way as in *Y. quadricolor*. Shown by Messrs. Veitch.

ROSE HEINRICH SCHULTHEIS.—A new Hybrid Perpetual, raised and exhibited by Mr. Bennett, of Shepperton. The blooms are large and full, and the colour a rich rose-pink. It is one of the finest of all Mr. Bennett's new Roses.

LEUCOTHOE DAVISLE.—A handsome evergreen shrub, lately introduced from California, where it grows from 3 feet to 5 feet high. It has rather small, deep green foliage, and bears at the tips of each branch clusters of small white blossoms, which, being abundant, have a pretty effect. It is a valuable addition to hardy shrubs. Shown by Messrs. Veitch.

PRATIA ANGULATA.—This little New Zealand plant has long been known in botanical gardens under the name of *Lobelia littoralis*. On this occasion it was shown in a profusely flowered state by Messrs. Veitch. The surface of the large pan in which it was growing was so densely studded with tiny white blossoms, as to appear to be quite a sheet of white. It is perfectly hardy, and is a capital plant for the rock garden.

ROSE VIOLETTE BOUYER.—A new Hybrid Perpetual in the way of Madame Lacharme; the flowers are large and full, and almost pure white, there being but a delicate suffusion of pink in the petals. Shown by Mr. Housé, Peterborough, and also by Mr. Wm. Paul, Waltham Cross.

BEGONIA ZENOBIA.—A double-flower tuberous variety, shown by Mr. Barron, from the Chiswick garden, on behalf of Messrs. Benary, of Erfurt. The flowers are deep crimson, and arranged in large, compact rosettes.

DELPHINIUM DICK SAND.—An extremely fine variety of the tall perennial class. The flowers are each as large as a florin, semi-double, and of an intensely deep violet-purple. The spike shown by Mr. Bealy, Roehampton, was much branched and the centre shoot densely furnished with flowers.

ROSE MRS. GEORGE DICKSON.—Another of the Hybrid Roses, raised by Mr. Bennett, of Shepperton. This is a Hybrid Perpetual variety with good sized blooms consisting of broad petals of firm texture of a delicate pink colour. Like Mr. Bennett's other Roses certificated this season, this will doubtless become popular.

BEGONIA ORANGE GIANT.—A tuberous-rooted variety, raised at the Society's garden, at Chiswick, whence it was brought for exhibition. The flowers are single, unusually large, and of good shape. The colour, a vivid vermilion-scarlet, is very telling, particularly when in contrast with that of others of duller hue.

VERBENAS FANTASTIC, with large trusses, pink flaked with crimson; COMPACTA, with an unusually long truss, the colour being a bright purple; MABEL, a pretty variety, of a delicate pink colour; and DELICATA, a soft mauve-pink. All these new seedling varieties were shown by Mr. Stacey, Dunmow, one of the few raisers of improved Verbenas now-a-days.

ORCHIDS were not numerous. Among them were some very choice varieties. The finest form of *Cattleya Sanderiana* we have ever seen was shown by Mr. Hardy. The flowers were very large, and the broad sepals and petals of a much deeper rose colour than usual, and the broad, shallow labellum, exquisitely frilled at the margins, was of an intensely deep amethyst. This splendid variety was the admiration of everyone, and it plainly exemplified what a beauty Sander's *Cattleya* is when represented in its best form. Mr. Hardy also sent a fine plant of *Laelia purpurata alba*, bearing two spikes, having four flowers on each. A plant of *Cattleya gigas* was sent by Mr. Fowler all the way from Ashgrove, Pontypool. It represented a very fine form of the species, the colour being rich and the flowers large. The finest variety as regards colour

of *Cattleya Warneri* we have seen was that exhibited by Mr. Gair, of Falkirk. The rose colour of the sepals and petals was uncommonly deep and uniform, and the amethyst-crimson tint of the labellum was intense. This and the variety exhibited by Mr. Hardy and certificated showed admirably what a wide range of variation there exists in *Cattleya labiata*, of which *Warneri* is a variety. Mr. James, Castle Nursery, Lower Norwood, had a few choice Orchids, conspicuous among which was the rare *Trichopilia picta*, a pretty species, producing a profusion of flowers with greenish yellow sepals and yellow lip. He had also the singular *Nanodes Medusa* in flower, as well as a rather distinct form of *Thunia alba* appropriately named *citrina*, which had the lip wholly of a citron colour. Mr. Stevens, of Trentham, exhibited a few fine forms of *Masdevallia Harryana*, one with the sepals curved and crossed in a peculiar way. A few very choice Orchids were also shown in the small group of plants from Mr. B. S. Williams' nursery, Upper Holloway. Among these were *Cattleya Morgania*, an extremely lovely variety of C. Mendeli, having large purple-white blossoms, save a dash of amethyst-purple on the labellum. There were also in Mr. Williams' group numerous other varieties of *Cattleya Mendeli* and *Mossia*, as well as of *Dendrobiums*, *Nepenthes*, and a choice collection of stove and greenhouse plants. A cultural commendation was accorded to Mr. Gilkes, Higham Hall, Walthamstow, for a fine spike of *Cymbidium Lowianum*.

CUT ROSES were abundant. Messrs. W. Paul & Son, Waltham Cross, had a large display, filling some eight or nine large trays. Among the sorts were several new ones, notably *Violette Bouyer*, which was certificated; *Queen of Queens*, one of the new Waltham Roses of great promise and shown better than hitherto. Then there was the beautiful *W. A. Richardson*, a new American Rose which captivates everyone, particularly ladies, who admire so much the soft gradation of tint in the flowers, which varies from a reddish buff to a creamy white. Besides this gathering of choice Hybrid Perpetuals and Teas there were some basketfuls of the old-fashioned Damask and Moss Roses, among the latter being the white *Blanche Moreau* and *Maiden's Blush*, both charming sorts still; Mr. Prince exhibited some of his Oxford-grown Roses, principally *Tea* and *Noisette* varieties, all of which were so fine as to anticipate Mr. Prince's usual successes at the forthcoming Rose shows. Mr. House, of Peterborough, showed the new Hybrid Perpetual *Hélène Paul*, which seems to be a fine variety. Besides the varieties certificated, Mr. Bennett exhibited other beautiful Hybrids, such as *Lady Mary Fitzwilliam*, *Earl of Pembroke*, *Mary Bennett*, *Countess of Pembroke*, and *Princess of Wales*, nearly all of which have received certificates.

NEW PLANTS shown by Messrs. Veitch, besides those certificated, included *Cornus brachypoda* variegata, a Japanese Dogwood with handsomely variegated foliage; *Acer polymorphum* dissectum variegatum, a long name for an extremely elegant form of the polyphormic Japanese Maple; *Daphnephyllum glaucescens* and variety *jezeuse*, both hardy Japanese shrubs of great promise; *Zenobia speciosa pulverulenta*, very fine flowering shoots of this handsome hardy shrub; *Heliotrope Roi des Noirs*, alluded to in another column; and three new erect flowered *Gloxinias* named *Diadem*, *The Daimio*, and *Mars*, all splendid sorts. Besides these were some glorious cut flower sprays of *Rosa Polyantha* and *Spiraea Aruncus*, the elegant white plumes of which being an unusual occurrence at an exhibition.

CUT FLOWERS and plants from Messrs. Cannell & Sons' nursery, Swanley, made a bright display. A score or so of tall spikes of *Delphiniums* were a beautiful feature distinct from anything else in the show. There were also from Swanley a large collection of *Pelargoniums* of the zonal type, both single and double, besides a numerous gathering of cut blooms of *Violas*, *Petunias*, *Verbenas*, and a host of other things, which are grown specially by Messrs. Cannell. An extensive collection of seedling zonal *Geraniums*

was exhibited by Messrs. Pearson, of Chilwell, some of which showed a decided advance on older kinds, especially in point of colour. A numerous display of double and single *Pyrethrums* and herbaceous *Pæonies* came from Messrs. Kelway, of Langport, who seem to be paying particular attention to these beautiful races of hardy plants, and with good results, judging by the produce they exhibit.

HARDY FLOWERS were shown finer than we have seen them for a long time, and the extensive collections from Messrs. Barr & Son, Covent Garden, and Mr. Ware, Tottenham, surpassed even those shown by the same exhibitors on the occasion of the last meeting. Messrs. Barr's collection was a very large one, and was made of groups of particular flowers arranged in a mass by themselves, and had a pleasing effect. There were English and Spanish *Irises* in abundance, *Columbines*, *Alstroemerias* in variety, French *Poppies*, Iceland *Poppies*, and *Poppies* of other sorts, including the new double *Papaver umbrosum*, which is a very handsome one, the flowers being quite double, and each petal has the characteristic black blotch at the base. Bearded *Irises* in great variety, *Ixias*, *Pyrethrums*, *Delphiniums*, *Lilium elegans* in numbers of varieties, and a splendid assortment of herbaceous *Pæonies* were also among this fine group, besides such curious plants as *Arum Dracunculoides*, the odour of which, however, was somewhat unpleasant.

A similar gathering of hardy flowers was that from the Hale Farm Nursery, Tottenham, which without question was the finest collection of choice hardy plants that has been exhibited for years. There were upwards of a hundred kinds, and with scarcely an exception were beautiful and interesting border of flowers. This included a fine series of varieties of *Irises*, Bearded English and Spanish *Pyrethrums* (single and double), *Pæonies*, *Snapdragons*, *Pentstemons*, double white *Rockets*, *Pinks* in great variety, including the new Mrs. Sinkins, the best of all the whites. Besides these we singled out the following, all of which are first-rate border plants:—

<i>Inula Oculus-Christi</i>	<i>Tropaeolum polyphyllum</i>
<i>Lychnis Viscaria splendens pleno (new)</i>	<i>Onosma tauricum</i>
<i>Spiraea Aruncus</i>	<i>Cyclobothra pulchella</i> and <i>alba</i>
<i>Campanula glomerata dahurica</i>	<i>Polemonium Richardsoni</i>
<i>Lathyrus grandiflorus</i>	<i>Phlox ovata</i>
<i>Lilium pomponium</i>	<i>Dictamnus Fraxinella alba</i>
<i>Colchicum parvum</i>	<i>Armeria cephalotes</i>
<i>Martagon</i>	<i>Sidalcea candida</i>
<i>Martagon purpureum</i>	<i>Gladiolus Colvilli</i> and its variety <i>The Bride</i>
<i>Candidum</i>	<i>Ramosus</i> in variety
<i>Longiflorum</i>	<i>Cypripedium spectabile</i>
<i>Auratum</i>	<i>Orchis foliosa</i>
	<i>maculata superba</i>

Among the newer and rarer plants shown were *Heuchera sanguinea*, an extremely pretty plant, flowered for the first time in this country; *Lilium pardalinum pumilum*, a rare and beautiful form of the Panther Lily; *Milla biflora*, not often seen in flower; *Senecio japonicus*, *Cyclobothra fusca*, and *Sprekelia formosissima*, cut from plants that have been in the open border for several seasons.

A cultural commendation was accorded to Mr. G. F. Wilson for a remarkably finely-flowered example of *Lilium Hansonii*, with a tall, stout stem, carrying about a dozen of its handsome flowers, of a rich yellow spotted with chocolate. Mr. Wilson also showed a stout flower-stem of *Lilium colchicum* bearing fourteen fine blossoms—a fine example of good cultivation. A new *Pelargonium*, named *Duchess of Connaught*, was shown by Mr. Dutton, Bath. It had prettily variegated foliage and dense trusses of double flowers of a flesh-pink colour. It was a very pretty plant, and much admired.

FRUIT AND VEGETABLES were rather numerous. A first-class certificate was awarded to a new seedling Melon named *Hollanden Favourite*, exhibited by Mr. Goldsmith, *Hollanden Park*, Tonbridge. It was a large, round fruit, well netted, and with thick, red flesh of delicious flavour. Mr. Goldsmith also showed another, called *Ilero* of *Hollanden*. Mr. Ross, of Welford Park, likewise showed a Melon, a seedling from William Tillery, and a seedling Melon also came from Mr. Hudson,

Gunnersbury Park, a cross between *Scarlet Gem* and *High Cross Hybrid*. For a fine collection of nine Pine-apples of The Queen variety, Mr. Harris, gardener to Mrs. Vivian, Singleton, Swansea, was awarded a silver medal. The fruits ranged from 4 lbs. to 5 lbs. each, and were remarkably uniform in size; and Mr. Laxton, Bedford, showed a new Strawberry named *The Captain*, stated to bear fruit perpetually from early June till late in September.

Messrs. Veitch & Co. contributed an interesting collection of early Peas, comprising fourteen kinds, all sown March 26, and their times of fitness for gathering were given, although some specified as ready several days previous were far from being fit to gather then, whilst the discrimination which detected a Pea as being fit one day earlier than another was of a remarkably discerning kind. Three kinds suitable for pot culture were *Little Gem*, *Minimum*, and *American Wonder*. These ranged from 9 inches to 10 inches in height, and the last was the earliest and best cropper, being ready on the 19th, as also was *Masterpiece*, height 14 inches, having full pods and a capital cropper; whilst *Optimist*, same height, was not ready till the 22nd. Of rather taller kinds, *Veitch's Extra Early* was ready on June 19, and *Laxton's First and Best* on the 19th, though the variation was not clear. *Alpha* and *Dr. Hogg* was both ready on the 19th, and both good croppers; whilst *Sunrise*, *Kentish Invicta*, and some others were poorly podded. Then the same firm showed several kinds of Onions, of which *The Queen* was the earliest and best sample.

Messrs. Carter exhibited baskets of various Lettuces from their trial grounds, but none were yet fully developed, although capital stocks of the respective kinds. *Victoria* was a handsome green Cabbage Lettuce, while *Stonehead*, one of the All the Year Round type, is doubtless the parent of that and many others. *Tom Thumb*, a pretty small green kind, was evidently identical with the more modern *Commodore Nutt*, and *Early Paris Market* was a large green kind, the leaves slightly tipped with purple. The American Green Fringed resembled a curled *Endive* and had no heart, and the American Gathering was the same colour as *Sutton's Marvel*, but much looser. The same firm also showed a large collection of new sorts of Peas, such as *Invicta*, *Little Gem*, *Tom Thumb*, *Earliest of All*, and *Holborn Gem*.

Special Prizes.

On this occasion the special prizes offered by Messrs. Webb & Sons, Stourbridge, and Messrs. Sutton & Sons, Reading, for vegetables, &c., were competed for. There were eight competitors for the four prizes offered by

Messrs. Webb for collections of six kinds of vegetables from fourteen named sorts, but all of an open choice. As might well be expected in the case of such small collections, the quality throughout was exceedingly high and even. Mr. E. Beckett, who was first, is a young exhibitor, but is taking a high place with vegetables amongst veteran growers. His collection included a fine dish of white Naples Onions, handsome Woodstock Kidney Potatoes, *Early London Cauliflowers*, solid and white; good *Telegraph Peas*, Canadian Wonder dwarf Beans, and very handsome *Early Nantes Carrots*. The second prize lot comprised *Earlier Leviathan Beans*, very fine; *Lapstone Potatoes*, a good sample; *Telephone Peas*, and with the same kinds of Carrots, Onions, and Cauliflower as in the first named collection. It was worthy of notice that in each collection were *Nantes Carrots* and *Early London Cauliflowers*, and all had Potatoes, whilst all but one had white Naples Onions, and of Peas four had *Carter's Telephone*, two had *Culverwell's Telegraph*, one *Carter's Stratagem*, and one *Webb's Kinver Marrow*. These figures show the average popularity of various vegetables for exhibition purposes.

Messrs. Sutton's prizes were offered for vegetables as under: First, for four dishes of Peas, any kinds except those otherwise specially named elsewhere in the schedule. In this class

there were four competitors, the average quality of the samples being far below that shown in the vegetable collections. Mr. Ward, gardener to Earl Radnor, Longford Castle, Wilts, was awarded the first prize, having very immature samples of Culverwell's Giant Marrow, a fine-looking sword-shaped Pea; Laxton's Supreme, a very fair sample; John Bull, also a pointed pod, but far from full; and Sutton's President Garfield, a fine-looking Pea of the British Queen type, and remarkably fine flavour. Nearly all the other sorts shown were small white-seeded forms of Sangster's No. 1 type, some, such as Kentish Invicta and First and Best, being wretchedly small samples. There was a large and spirited competition in the next class for six kinds of Lettuces, three heads of each kind. Here Mr. Beckett was again first with fine, well-selected samples, of such excellent sorts as Sutton's All Heart, a handsome, Solid Green Cos, and their Superb White Cos, very like the other, but lighter in colour. Of Cabbage kinds there were capital samples of Blonde de Berlin, a handsome, smooth-leaved, yellowish green kind, with firm, solid heart; the well-known All the Year Round; and the purple kind Marvel, a very fine solid-hearted kind. Other exhibitors had good Paris White Cos and St. Albans All Heart, but, of course, all this section are either the old trade strains of Paris White or Green Cos, though some may be better stocks than others. Of other Cabbage kinds were Standwell and the little Commodore Nutt.

SCIENTIFIC COMMITTEE.—A. Grote, Esq., in the chair.

Melon leaves diseased.—Mr. G. Murray reported that he had examined the leaves sent by Mr. Boscawen to the last meeting, and found that the treatment of sulphur and lime had quite destroyed the fructification of the fungus, but the mycelium was still present within the tissue of the leaf. He thought it might prove to be a *Peronospora*, but would examine it further and report.

Potato disease.—Mr. S. Wilson forwarded fresh material for Mr. G. Murray to examine, remarking that the results of the chemical tests he had applied were that the so-called sclerotia were insoluble in spirit, not coloured by iodine, but are soluble without effervescence in nitric acid; they are also soluble in acetic acid. Alkaline tests had not been applied. They fall out readily from macerated tissue not being in the cells, but between them. Mr. Wilson adds that Professor Dickson distinctly denies that they are tubercinia or protomyces. Mr. G. Murray will report further on the nature of these sclerotoid bodies.

Achenilla vulgaris.—Mr. G. S. Boulger exhibited a fine specimen of the common Ladies' Mantle grown in a garden for three years, and which formed a very ornamental plant.

Pinus Thunbergi (Massoniana of gardens).—Dr. M. T. Masters showed young cones of this species having anthers at the base. He observed that he had seen a similar occurrence in *P. rigida*.

Torsion in Sweet Williams.—Mr. Bennett exhibited a stem showing the spiral arrangement of the leaves by torsion. It is observable that the opposite and decussate arrangement characteristic of all the Caryophyllaceæ is not departed from, but one leaf of each pair grows slightly more elevated than the other, thus producing the torsion. Teazle stems thus grown (from seed) were used as parasol handles under the name of Eucalyptus.

Deformed Digitalis.—Mr. Loder showed a plant where the terminal flower had grown in a campanulate form by two or three having combined. It was fully expanded, though the raceme was blossoming upwards as usual.

Plants exhibited.—Col. Clarke showed a blossom of a Hibiscus, probably Hugeli. From Mr. C. Green came a hybrid Begonia, *B. argyro-stigma* crossed by *B. sanguinea*.

Ranunculus aquatilis.—Mr. Henslow showed a specimen growing on damp soil in which several of the usually floating leaves were partially divided, showing a transition to the filiform state; while the latter, which formed a perfect carpet, were provided with abundance of stomata, though when submerged they are devoid of them.

PELARGONIUM SOCIETY.

JUNE 26.

THE annual exhibition of this Society, held as usual in the gardens at South Kensington, was as brilliant as its predecessors, and the number of exhibitors was perhaps larger than hitherto, but amongst exhibitors there seemed to be no new recruits, the same familiar names being on the prize list as in former years, and in much the same positions. This is not the fault of the Society, the schedule being most comprehensive, but rather an indication that there is really not so widespread an interest taken in the Pelargonium as in such flowers as the Rose, which is exhibited from all parts of the kingdom. The quality of the specimen plants was not up to the average, a circumstance probably attributable to the hot weather experienced a short time ago, having a tendency to defoliate the Pelargoniums. Throughout the whole of the plants shown there was a conspicuous thinness in growth, and the redundancy of sticks which some of the exhibitors used to prop up weakly flower-stems was most unsightly. As on previous occasions, there was a marked absence of anything strikingly new. Notwithstanding the fact that upwards of £15 were offered by the Society for hybrid varieties, there was not a single plant partaking of that character. Such work, nevertheless, may be going on, though we may not see its results, at least at exhibitions, for some years to come. Some new departure is greatly wanted now that the climax of perfection has apparently been reached with regard to most of the types of Pelargonium, except perhaps the Ivy-leaved class. This exhibition, it may be added, was visited by a large and appreciative company.

NEW VARIETIES were but sparingly produced, and there was no trace of any new forms of the Cape species or any other of the types that are less known. The large-flowered Pelargoniums, both of the show and decorative types, were most largely represented in the shape of new forms, but as only one certificate of merit was awarded in this section, it may be assumed that there was little of special novelty or quality among them. Mr. E. B. Foster, Clewer Manor, Windsor, had the best three new large flowering (show) Pelargoniums, and was awarded the prize for Adventure, a pretty pink flower with dark top petals, fine form; Brilliant, rich orange, deepening to scarlet, showy, and of good form; and Diadem, lovely orange, shaded dark, dark top petals, and white throat, all very pleasing varieties, raised by the exhibitor. In the class for two plants, Mr. C. Turner, Royal Nursery, Slough, staged Pioneer (Foster), a bright-coloured variety of showy character; and Confessor, a pleasing orange-pink flower, dark top petals and good form. Mr. H. Little, Hillingdon Place, was awarded the prize for one plant, staging Mrs. H. Little, raised by himself, having pure waxy white lower petals and black and purple upper petals, very pretty, and good in habit. The new fancy Pelargoniums were few in number. In the class for three varieties Mr. Turner was the only exhibitor, having Butterfly, Cherry-ripe, and Irene, none of them in good condition, the last the best—a pretty pale variety of decided promise. There was no competitor in the class for one or for two plants. New decorative varieties were fairly numerous, but not generally of such good quality as the show types. Messrs. J. & J. Hayes, Edmonton, had the best three varieties, receiving the prize for Bouquet, pure white, the flowers much fringed on the edges, very fine, and excellent in habit; Fanny, delicate pink, also much fringed, very pretty and distinct; and Formosum, brilliant deep orange, very showy. From Mr. H. Little came Rayonette, a free-flowering, bright-coloured variety; Pink Perfection, and Mauve Queen, both very novel in appearance. Mr. W. Brown, Brent Nursery, Hendon, was first with two decorative sorts, viz., Lustrious and Beacon, both fine, bright red flowers of good form and very free, also with excellent habits of growth. Mr. Brown has raised some excellent market varieties, generally of bright and striking colours. Mr. Turner had the prize for one new decorative variety, staging Dresden China, a sin-

gularly novel Pelargonium, having white flowers stained and flaked with pale rose, but with a tendency to sport, as some of the flowers were white, with a slight dark spot on each petal. Mr. H. Little had Rosette, a pale pinkish red, but not of good quality. Of new zonal Pelargoniums (single) there was a poor display. No award was made in the class for three plants, the varieties shown not being good enough; in the class for two plants there was no entry; in that for one plant there was no award; in the class for three double zonal varieties there was no award, the only exhibitor being Mons. Victor Lemoine, Nancy, who had unnamed seedlings. There was no entry in the class for two plants, and in that for one plant no award was made.

Of new Ivy-leaved Pelargoniums, Mons. V. Lemoine showed in the class for three doubles La Rosière and Jeanne d'Arc, both of good properties, and a seedling, but no award was made. Mr. J. George showed his new variety, Future Fame, which the floral committee a short time since thought good enough for a first-class certificate.

COLLECTIONS were more numerous, but the specimens on the whole were below the average quality of the past few years. As usual, Mr. Turner, of Slough, and Mr. Little, of Uxbridge, were the only competitors of show and fancy specimens. The six best show kinds from Slough were large and admirably flowered. They represented such beautiful sorts as the old Victory, Despot, Modesty, Archduchess, Mountaineer, and Amethyst, as fine a half dozen as could be selected. The large specimen of Amethyst was really superb, and was selected by the judges as the best specimen in the whole show, for which the Royal Horticultural Society offered a silver Banksian medal. The colour of Amethyst is a beautiful rich purple, with the upper petals of a deep maroon. It is distinct from any other variety as regards colour that has been raised, and it combines with this splendid colour dwarf and compact growth and a remarkably free flowering habit. It was sent out two or three years ago by Mr. Turner, and the fortunate raiser of it was M. Bréhaut. Those who care for show Pelargoniums should by all means possess this one. Mr. Little's second best six were fairly good, the best being Claribel, one of the finest light sorts; and Illuminator, the brightest of all the shows, the colour being a glowing vermillion-scarlet, set off by a clear white centre. The two collections of fancy varieties were shown by the same exhibitors, Mr. Turner's being again the best. His plants were profusely flowered, and averaged about a yard in diameter, the sorts represented being Mrs. Pope, Lady Carington, Mrs. Pottle, Nellie Fordham, Pilgrimage, and Delicatum. In the other group were beautiful examples of Polar Star, Duchess of Edinburgh, and Delicatum. In the class for eighteen show kinds, in 6-inch pots, Messrs. Little and Turner were again the only competitors. In the first collection, from Slough, were several beautiful new sorts, such as Cornet, orange-scarlet with maroon upper petals; Royal Review, one of the finest of all the show class, the flowers being of perfect shape, and of a rich crimson, and dark upper petals edged with crimson; Seyla, pale rose-maroon, crimson upper petals and white centre; Zealot, bright scarlet and of fine shape; Statesman, a pleasing rose with dark top petals and white centre. All these are new sorts now being distributed for the first time; but besides them such excellent sorts as Amethyst, Rob Roy, Martial, Fortitude, The Baron, Morning Light, Joe, Monarch, and Sunbeam, the last being probably the brightest scarlet of all.

THE FRINGED or decorative varieties were the most numerous, a fact that points to the rising popularity of this section, which is now so largely grown for the London markets. The varieties of these are becoming very numerous, and among the most successful raisers are Messrs. Hayes, market florists, of Edmonton, who were the principal prize takers in the classes for this type of Pelargonium. The best six came from them, the specimens being large, profusely flowered, and altogether fine examples of skilful culture. The

sorts were Mrs. Bradshaw, Garibaldi, Lady Isabel, a distinct and lovely tinted variety; Duchess of Bedford, one of the best whites; and Gold Mine, a splendid new sort, the brightest of its colour (a glowing scarlet) yet raised. In Mr. Little's second best six were such excellent sorts as Madame Favart, Duchesse de Morny, Triomphe de St. Mande, and Digby Grand. The other six were from Mr. Turner, who had several fine varieties of the Regal type, such as the vivid Carl Klein, Dr. Masters, besides Volonté Nationale, Madame Thibaut, and Comtesse de Choiseuil. The class for eighteen plants in 6-inch pots was also best represented by Messrs. Hayes, who had several novelties, such as Madame Marie Knecht, the best pure white yet produced, and one of excellent habit; Mrs. J. Hayes (rosy pink), Gold Mine, Metallica, Robina, Emma Hayes, and numerous other excellent kinds. In the next best collection from Slough, Robina, Lady Blanche, Decorator, Mrs. J. Hayes, Maid of Kent were striking varieties; and among those from Mr. Little those named Zulu Belle, white with conspicuous black blotches; Blushing Bride, new; Miss Alice; Goliath, new, were the most noteworthy. The other two exhibitors in this class were the Messrs. Brown, both market florists at Hendon.

ZONAL VARIETIES throughout the whole of the classes were poor; even Mr. Weston, who usually shows some astonishing productions amongst the single kinds, was not up to his usual mark, though he had no difficulty in taking the principal prize in the class for six. His group consisted of Rosamond, Lucrezia, Hettie, Laura Strachan, Rev. Atkinson, and Lizzie Brooks. The plants were trained in the broad Mushroom-shaped fashion, and of course were very showy. The other collections were poor in comparison, as were also the collections of eighteen plants, the best being much inferior to those shown on previous occasions, the plants being rendered unsightly by a redundancy of sticks. The double zonal varieties, too, evinced the same fault, and the paucity of foliage made it more bare; indeed, the double zonals were so poorly represented in the class for six specimens, that the judges refrained from awarding the first prize. The Ivy-leaved class was only exemplified by one collection of nine; this was from Mr. Little, the specimens being large tall pyramids, well furnished with bloom. The sorts represented were M^{me}. Emile Gallé, M^{me}. Jean Wouters, Perle, Sarah Bernhardt, Eurydice, Elfrida, Anna Pfitzer, and Gloire de Orleans. The collections of cut blooms made, on the whole, a very creditable display, the principal prize winners being Messrs. Turner, Cannell, Saltmarsh, Meadmore, and Little.

THE CERTIFICATES of the Society were awarded to the following La Cygnée, shown by Mr. W. Bealby, Roehampton. It was a zonal variety with large massive trusses of white flowers, though not quite pure, being shaded slightly with green. However, it is the best double white at present raised, and seems to be a free grower and flowerer. Mr. Little showed the other certificated plant, which was named Mrs. H. Little, and belonging to the show section. It is a most distinct variety, having large finely-shaped flowers, the lower petals of which are white, while the upper two are a deep maroon-crimson, a striking contrast of colours. The habit is sturdy and dwarf, but the plants shown were poorly flowered.

A full list of awards is given in our advertising columns.

WAVERLEY PANSY SOCIETY.

THE annual exhibition of this Society was held at Galashiels on the 16th inst. The number of entries in the various classes was more numerous than in former years, while the quality of the flowers was all that could be desired. There were eight competitors in the nurserymen's section, the principal awards in which were as follows: Twenty-four show Pansies.—1 (silver medal), Wm. Paul & Son, Paisley, with beautiful flowers of Artemus, A. Miller, Harry Paul, J. P. Barbour, P. Barr, Rev. J. Morris, dark self; Gomar, Geo. Rudd, yellow self; Mrs. Dobbie, Mrs. Turnbull, white self; The Mede, Mrs. J. Millar, Mr. J. G. Paul, Mrs. D. Wallace, Miss Meikle, Jessie Foote, Nellie Corbett, white grounds; Try me Oh! J. B. Robertson, D. Dalglish, Lizzie Bullock, A. Henderson, D. Robertson, Seedling No. 1, yellow grounds. 2, Messrs. Dicksons and Co., Edinburgh. Twenty-four fancy Pansies.—1 (silver medal), Mr. J. Sutherland, with grand blooms of Catherine Agnes, D. Main, W. McIntosh, Mrs. J. Stewart, Mrs. McTaggart, J. Murray, Perfection, John Stewart, May Tate, Ruby, Miss Reeve, General Grant, Mrs. Findlay, Mrs. Murdoch, Earl Beaconsfield, Miss Bliss, W. Dickson, Mrs. Duncan, D. Wallace, and seedlings. 2, Messrs. Laird and Sons, Edinburgh, whose exhibit included George Ross, James Gardner, Prince Silverwings, Archie Bowe, W. Cuthbertson, Luck's All, Lady Falmouth, Hon. G. R. Vernon, W. Windle, Mrs. Forrester, Mrs. E. H. Wood, and A. McMillan. Gardeners' and amateurs' class: Eighteen show Pansies.—1, (silver medal), James Skinner, Penicuik, with A. Miller, Manve Queen, Peter Lyle, Rev. J. Morrison, dark self; Gomar, yellow self; Agnes Fairgrieve, white self; Miss Barr, Miss Meikle, Mrs. J. G. Paul, Miss Ritchie, Jessie Foote, Mrs. J. Millar, white grounds; Corsair, J. B. Robertson, R. Donaldson, J. Bucha-

nan, John Bruce, Try me Oh! yellow grounds. 2, Mr. L. T. Fleming, Berwick. Eighteen fancy Pansies: 1 (silver medal), Mr. Jas. Gowans, Hawick, with May Tate, Miss Bliss, Catherine Agnes, Jas. Gardner, A. McMillan, Perfection, Rev. J. Graham, Mrs. Jameson, Mrs. Barrie, W. Cuthbertson, Miss Reeve, and others. 2, Mr. J. Black, East Calder, who had specially fine Bob Montgomery, R. K. Mitchell, Ruby, Mrs. T. McComb, Countess of Home, Mrs. J. Stewart, and G. O. Trevelyan. Best show Pansy: Miss Bowie (primrose self), Mr. Jas. Black. Best fancy Pansy: Miss Bliss, Messrs. Laird & Sons. Best white ground show Pansy: Jessie Foote, Mr. J. S. Armstrong. Best yellow ground show Pansy, David Dalglish, Mr. Jas. Bowie, Galashiels.

Pansy (M. M.).—By no means new, but distinct, and well worth growing.

Bronze Pansy (Myton).—We can find no mention of the Pansy you name in the report on question.

Pink Malmaison Carnation (J. B.).—A very distinct and pretty sort, but not new. It was shown a year or two ago in London.

Gloxinas (G. A. F.).—Your question appeared in THE GARDEN (see p. 575). Can you send us a bloom or two for inspection?

Pansies (Messrs. Carter).—The flowers sent are large and beautiful, deep and rich in colour, edged in some cases with bright yellow, in others with buff and flame colours, and in others again with white—a charming strain.

Names of plants.—*L. A. C.*—1, *Astrantia major*; 2, *Centaurea montana*.—*Bete.*—A deformed flower of some *Cattleya*; the other (yellow) is *Oncidium sphacelatum*.—*A. Wallis.*—*Stanhopea tigrina*.—*Col. Wortley.*—*Erigeron grandiflorum*.—*D. H. P.*—*Veronica Teucrium* var. (blue); the other is *Hesperis tristis* (Night Scented Rocket).—*X. Y. Z.*—1, *Æschynanthus grandiflorus*; 2, *Diplacus glutinosus*.—*Anon.*—1, *Geranium macrorrhizum*; 2, *Hieracium pilosella*; 3, *Acæna pulchella*; 4, *Crepis aurea*.—*Capt. Coleridge.*—A fair variety of *Oncidium stelligerum*.—*E. Beveridge.*—*Oncidium altissimum*.—*R. V. & Son.*—The *Pæonies* belong to the herbaceous, not the Moutan class, but we do not know the names.—*Berthons.*—*Jasminum Sambac*.—*W. N.*—*Thalictrum aquilegifolium*.—*A. Locke.*—*Orchis maculata*.—*De B. Crawshaw.*—*Digitalis grandiflora*.—*E. F. T.*—1, *Aspidistra lurida*; 2, *Lilium Martagon*; 3, *Silene inflata*.—*G. Jupp.*—*Stanhopea bucephalus guttata*.—*Constant Reader.*—1, *Gymnogramma calomelanos*; 2, *Selaginella Kraussiana* (denticulata of gardens); 3, *Adiantum pubescens*; 4, *Pteris serrulata*.—*C. W. H.*—*Amelanchier canadensis*.—*C. L. C.*—1, *Allium* species; 3, *Allium Moly*; 4, *Lotus corniculatus* fl. pl.; 5, *Doronicum Pardalianches*.—*T. S. U.*—*Acropera Loddigesi*.
